Note.—The yields given above are from the pumping records after beginning to utilize the spring. Observations in 1890, before beginning to pump, showed a natural flow in gallons per 24 hours, as follows: Minimum, 246,818; average, 274,320; maximum, 310,532; equivalent to about 100,000,000 gallons for the year. Pumping continuously from the well excavation for 21½ days the yield in gallons per 24 hours was as follows: Minimum, 415,152; average, 440,479; maximum, 519,840.

This spring is in a direction from the well nearly at right angles to the course of the brook. There are two brooks between, and the spring supplies a third and would naturally be considered in a different watershed, although the dividing line is not pronounced. From its location and the circumstance mentioned it is probably fed by the same reservoir. It does not follow, however, that the same or similar conditions always exist concerning any two springs that may be somewhat near each other, or even in the watershed of the same brook, for their particular watersheds may be distinct, separated by a barrier and uncommunicable, as might be the case with two springs on opposite sides of a wide valley.

The location of the Seaverns Spring in Lexington, Mass., is an example of the latter situation, being at the toe of the slope on the opposite side of the valley from the spring-wells and pumping station of the town supply, with a deep muck deposit intervening. No records have been kept that would determine beyond question that long continued pumping on the wells does not affect the flow of the spring, but from such observations as have been made it is probable that the spring is not seriously affected, if at all.

In a preliminary study of the probable quantity to be depended upon, it would be on the safe side to consider a spring-well supply, on the basis of an ordinary ground water, at the place under consideration, and estimate the quantity in accordance with the method described in Mr. Frederick P. Stearns' paper on "The Selections of Sources of Water Supply," under the heading "Quantity of Ground Water," printed in the "Journal" of the Association for March. 1892.

While it is possible that a spring-well as usually situated may not furnish as much water as a well located in open porous material with a direct watershed of the same area, it is very probable that it will furnish more water than could be expected from the same watershed in which it is located, were the spring and its supply channels absent.

Mr. J. T. Fanning, in his treatise on "Hydraulic and Water Supply Engineering," states that, "from springs, with the aid of capacious storage reservoirs, it might be possible to utilize 50% of the above (referring to accompanying table) volume of percolation. From wells, it would rarely be possible to utilize more than from 10 to 20% of the volume."

For the purpose of affording opportunity for comparison with other springs, the following data, compiled from observations made before and during construction, and from the pumping records since, is given concerning two springs that have been utilized for town supplies six and five years respectively.

The Porter spring constitutes the present supply for the town of Avon, Mass., having a population of 1,626. The watershed of the brook draining the valley has an area above the location of the spring of about 0.5 sq. mile, with possibilities for a reserve supply; and the formation of a considerable portion of the territory is of a fairly absorbent nature, 30 or 40 acres tributary to the spring being especially favorable.

The table shows that during the last three years the quantity of water pumped exceeds the average natural flow as observed in 1889, demonstrating that the normal capacity of a spring is not the measure of the capacity of a well at the same location, the difference in quantity being made up from the storage reservoir. In 1894, the year of least rainfall, the quantity pumped was but 6% of the total rainfall, indicating that much water runs to waste during wet seasons.

The minimum natural flow was measured after a period of 19 days when the rainfall was so slight that probably none of it reached the water table; and the maximum, following a fall of 2.44 ins. These figures show the variations springs are subject to in direct consequence of variations in the rainfall.

The quantity pumped during a short preliminary trial of 53 hours was an aid in studying the source, and indicates pumping possibilities in a similar season when the storage reservoir has not been drawn upon for too long a period to permit of it, as does also the quantity pumped at a trial of the permanent pumping plant for determining its capacity per minute and steaming qualities, at which time 103,555 gallons were pumped into the stand-pipe in a run of 2 h. 43 min.

The Colburn spring supplies the town of Needham, Mass., which had a population by the 1895 census of 3,511. The brook nearby has a watershed above the spring of about 0.9 sq. mile, which is particularly adapted for absorbing a fair percentage of the rainfall. The yield of this spring is shown by Table II.

It is evident from the Needham records that the water required in 1895 was a little more than one-half the natural flow of the spring, and that the maximum demand has not required a draft upon the reserve in the main storage reservoir, 251,102 gallons being the maximum pumping for one day in 1894, the year of low rainfall.

The greatest natural flow observed in 1890 was on April 10, nearly 1 in. of rain having fallen the day before, and the least flow on Aug. 25, after nearly three months in which there was a deficiency of rainfall and in a season when it is doubtful if the water table received any replenishment.

The quantities pumped from the well excavation during construction are of interest, as the pumping occurred immediately after the deficiency in rainfall before mentioned and when little or no water was running in the brook above the spring. The pumping covered a space of 2½ months, and during three periods was continuous; one period of 11 days, one of 21.5 days, and the third of 12 days, with a dry spell of two weeks occurring during the longest period. The least quantity pumped was during three days at the end of the dry spell, and as given in the table was 415,152 gallons, which amount represents 20% of the average daily rainfall for the twelve months preceding.

By the third day after pumping ceased at the end of this space of 2½ months, during which time the quantity pumped and the natural flow exceeded 23,000,000 gallons, the spring had resumed nearly its usual flow.

The Colburn spring, originally consisting of three distinct springs, within a radius of 110 ft. of each other, is not far from the Charles River. This locality is near the middle of a long detour which the river makes about the town, almost semi-circular in shape for a distance of about nine miles. The town is practically enclosed by it on three sides, the main villages being situated near the center of the bow on elevated land about a mile from the river. The watershed of the brook is east of the villages and comprises a portion of the Needham Plains before referred to, with an absorbent area of a hundred acres or more where the formation is very porous and the water table 25 or 30 ft. below the surface.

The location of the works is particularly fortunate in possibilities for the future when the town outgrows the supply from the well; not the least of which is the opportunity to obtain a ground supply near the river; legislative right to a daily quantity of 500,000 gallons from it having been obtained by the town.

The supply works are designed with a view to future additions, the pumping station being located nearly midway between the spring and river. This renders the connection between pumps and well longer than ordinarily advisable for a direct suction. It was determined by considerations of the best location for the station, present and future, together with the fact that the extra friction in the suction pipe would be of little consequence in this case, as there is a back head of 2 ft. on the pump discharge valves when the well is full, and the maximum lift is but 19 ft. The suction pipe is 12 ins. in diameter, 970 ft. long and laid on a true grade.

The spring well is circular, 22 ft. in average diameter, 24 ft. deep, built of open-jointed rubble masonry, with a lining of brick laid in cement mortar, for the upper 18 ft., and is surmounted by a conical shingled roof. It was built at the largest and highest of the three springs, and the sites of the other two were sealed over by beds of concrete, while the water was kept down by pumping from the well. The outlet is 1½ ft. below the top of the well, which overflows between times of pumping.

The pumping plant is in a substantial brick building, is operated by steam, the machinery is duplicate throughout, designed for economical operation and has a total capacity of 1,500,000 gallons in 24 hours. The plant is connected with the distribution system ¾ mile away by a 10-in. force main.

PARIS TRAMWAYS, PAST AND PRESENT.

According to a report prepared by Mr. Graham, of the British Embassy at Paris, tramways were introduced into that city in 1853 by Mr. Alphonse Loubat, who had just returned from a trip to the United States and saw them tried in New York. They were at first called "Chemins de Fer Americains." On Aug. 16, 1853, a trial took place in Paris, which was fairly successful, and on Feb. 18, 1854, an imperial decree authorized M. Loubet to establish and operate horse-tramways between Sevres and Vincennes. In 1856 this right was transferred to the Compagnie Generale des Omnibus. The Loubet concession provided for the building of about 18 miles of line, of which 5 miles were not built until about 1874.

In 1893 the urban and extra-mural systems of Paris tramways extended over 230 miles, and they carried annually over 158,000,000 passengers. The city of Paris is not entitled to any portion of the receipts from these lines, except as covered in the following taxes and rents: A ground rent for offices, stations and shelters erected on the highways and a tax of 6 cts. on each car starting from a terminus within Paris. The city receives annually about $23,500 as rent for offices, etc. The State receives nothing from tramway enterprises: not even the 3% wheel-tax levied on ordinary carriages.

A decree of Aug. 6, 1881, fixes special conditions which tramway companies must comply with in the construction and operation of their lines. All plans must be approved by the Minister of Public Works and the Municipal Council, and these plans cannot be modified without the consent of these parties, though the administration may order such changes as will not give grounds for indemnity. The companies are answerable for the conditions of the highways over which the lines pass; and in cases of neglect the streets may be repaired by the city at the users' expense.

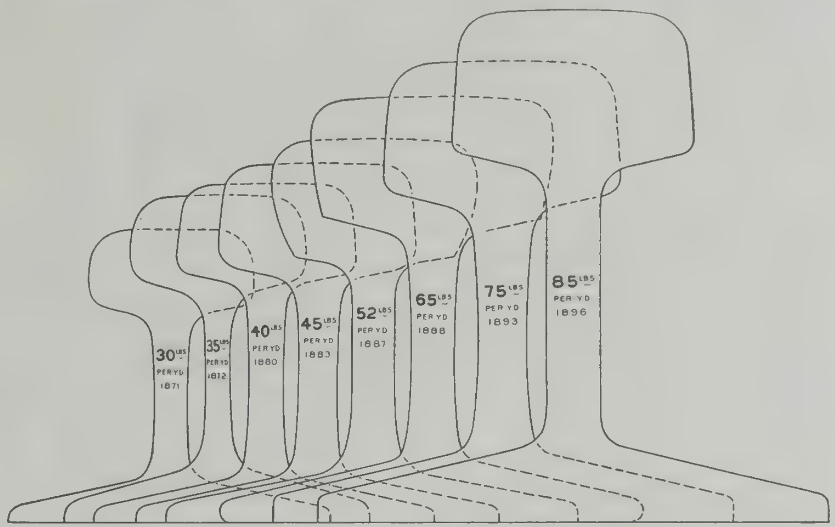
The maximum speed of steam tramways is fixed at 12½ miles per hour; and if there is danger to the public safety from any cause, the working of the line may be stopped or it may be given to a new company to operate. The city has the right to cross any tramway with roads, railways or canals without indemnity to the tramway company; and any concession for a tramway may be withdrawn at any moment if such a step is deemed to be of public benefit. The administration may grant concessions for new lines branching from the lines of old concessions without any indemnity to the original company. The two companies, in such a case, must come to an agreement regarding the use of each others' lines, stations, etc.; and in case of disagreement the decision of the Minister of Public Works is final. In the Department of the Seine control over the construction and operation of tramways is exercised by the Chief Engineer of the department, assisted by two engineers of the "Ponts et Chaussees," and one engineer of mines under the Prefect of the Seine and the Prefect of Police. The Chief Engineer is paid 3,000 francs, or $600, annually for these services, and his assistants are paid each 1,000 francs, or $200 annually—presumably in additions to other salaries.

The tariffs are fixed by the "Cahier des Charges" and must be approved by the Minister of Public Works for all state concessions, and by the prefect in all departmental or communal concessions. In Paris, the usual charges over the whole or any part of a line are 6 cts. for first-class and 3 cts. for second-class passengers. The first class have seats in the interior and are entitled to "correspondence," or transfers on any abutting or intersecting line having transfer offices; the second-class ride on top and have no rights of "correspondence" without an extra charge. Children under 4 years and bundles not exceeding 22 lbs. in weight are carried free. The administration may require, except on Sundays and national holidays, special cheap service for working classes with only second-class fares.

The lines are generally worked by horses, but mechanical power is making rapid progress. Ordinary and fireless steam locomotives, compressed air and electric motors are now used on several lines and the Belleville tramway is operated by a cable. The rails are of the American flange and Broca or Marsillon types.

RAIL SECTIONS OF THE DENVER & RIO GRANDE R. R.

The various forms of rail sections which have been used on any one railway of considerable age and length would make an interesting set for comparison, and we illustrate herewith a comparative set of the sections which have been used on the Denver & Rio Grande R. R. since 1871, when the construction of that road was commenced. There are eight sections, ranging from 30 to 85 lbs. per yd., and dating from 1871 to 1896, and these represent three different types of head. The first two (30 and 35 lbs. per yd.) have heads with round corners and sides, the second approximating somewhat to English sections. The next two (40 and 45 lbs. per yd.) have heads with outward flaring sides and very round corners. The next two (52 and 65 lbs. per yd.) have inward flaring heads, which is a distinctly objectionable form of section, and it will be noted that while the first of these (52 lbs. per yd.) has rounded sides to the head, the second (65 lbs. per yd.) has the sides very nearly plane. In the last two rails (75 and 85 lbs. per yd.) the section approximates to what is now practically the standard type of section, although the top corners of the head are of rather larger radius than is usually considered advisable.



COMPARATIVE SECTIONS OF RAILS USED ON THE DENVER & RIO GRANDE R. R. FROM 1871 TO 1896.

Our cut is reproduced from a page of the tenth annual report of the railway company, being for the year ending June 30, 1896. This report states that during the year 9,255 tons of rails were received and paid for, of which 5,266 tons are of the latest section, 85 lbs. per yd., as the management has deemed it prudent to increase the weight from 75 to 85 lbs. per yd. on these portions of the standard gage main line where the traffic of the system is concentrated and the speed of passenger trains is greatest. The heaviest rails used last year were laid north of Pueblo, Colo., and it is the intention, in the near future, to relay the balance of the 92 miles of single main track between Denver and Pueblo, with 85-lb. rails, provided the earnings permit of the expenditure. The relaying of the 28 miles of double track between these points will be deferred until a later time. The second-hand rails released by the laying of new ones are used upon other parts of the system to replace lighter rails now in use. Upon the standard gage main line between Denver and Grand Junction, 455 miles, and the Trinidad Branch, 91 miles, there are no rails of less than 65 lbs. per yd. carrying standard gage equipment. It is of interest to note that where the 85-lb. rails are used in the three-rail or mixed gage track, which extends from Denver to Leadville, 278 miles, the middle rail for the narrow gage (3-ft. gage) equipment weighs 65 lbs. per yd., making the total weight of steel rail 235 lbs. per yd. In an article on the Erie R. R., in our issue of Jan. 9, 1896, we referred to the use of 80-lb. and 74-lb. rails on opposite sides of the same track, but the Denver & Rio Grande R. R. goes even farther in using the above noted combination of an 85-lb. and a 65-lb. rail. It would be interesting to know whether this affects the riding quality of the track for the narrow gage trains.

WATER DEVELOPMENT ON THE MOJAVE RIVER, NEAR DAGGET, CAL.

By J. B. Lippincott.

The Mojave River rises on the northern slope of the Sierra Madre Mts. in San Bernardino Co., Cal. Its course is semicircular, flowing progressively west, north and then east, and, as is common in the arid region, decreasing in volume as it progresses until the surface flow at last disappears in the sandy bed a short distance below Barstow.

The headwaters of this stream flow from elevations of 5,000 to 8,000 ft.; it sinks at an elevation of 1,900 ft., the foothills of these mountains being 3,000 ft. above the sea.

The basin may be classified in three parts: Mountainous, containing 251 sq. miles; foothills of 219 sq. miles; plains and desert buttes, 1,000 sq. miles; thus making a total drainage area above Dagget of 1,470 sq. miles. These areas were taken by a planimeter from the county map.

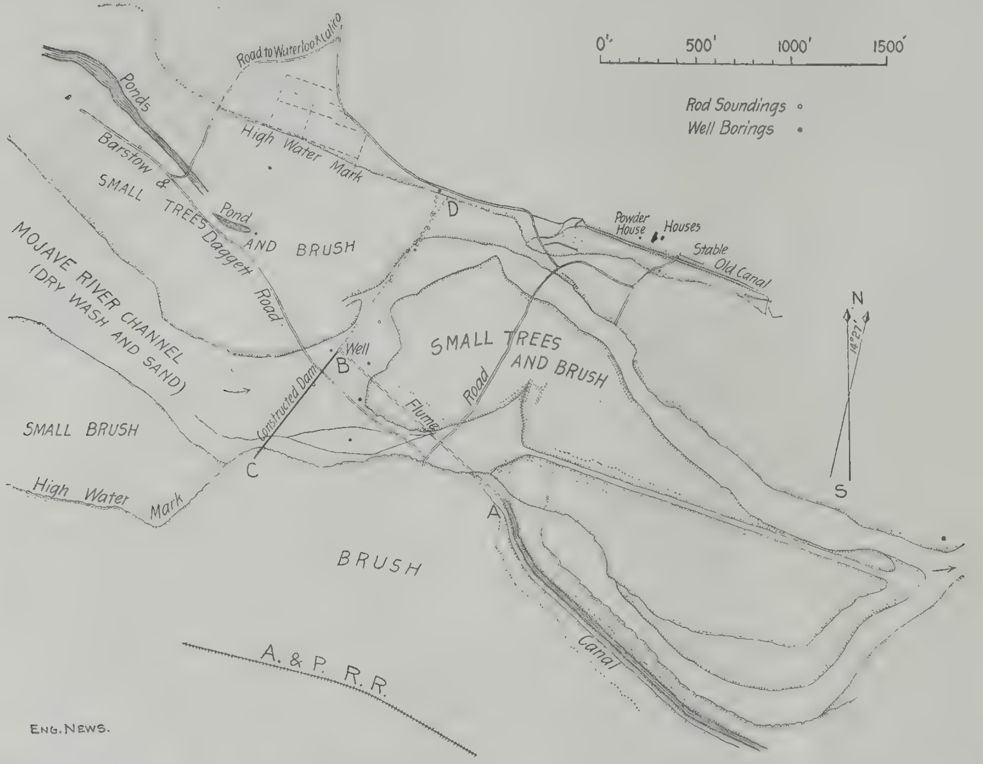


FIG. 1—SUBMERGED DAM SITE ON THE MOJAVE RIVER NEAR DAGGETT, CAL., FOR THE IRRIGATION SYSTEM OF THE SOUTHERN CALIFORNIA IMPROVEMENT CO.

To the west there are many mountains that drain toward the Mojave desert, but the streams, which are small and few in number, disappear as soon as they reach the hot sands of the desert. The general slope of this great valley is toward the Mojave River from the west, at the rate of 2 ft. per mile, but the rainfall is so light, about 3 ins. per annum, and the summer heat so great that the runoff, to say the least, is not on the surface.

The rainfall on the coast ranges of Southern California increases with the elevation of the range on the side toward the sea until the summit is reached, the heaviest precipitation being just over the crest. This increase discontinues, however, above an elevation of from 6,000 to 7,000 ft., at a point not well determined. The rainfall at the heads of this river has been well measured by the Arrowhead Reservoir Co. Just north of the crest and in the basin of the Mojave River the rainfall is 60 ins., and from that maximum it falls rapidly to an average of 2.6 ins. per annum at Barstow. It will be remembered that the storms in southern California occur between October 1 and May 1, the greater portion of the rain falling during the months of December, January and February. They are frequently very violent and the fact that the ground is so dry, provided the storm is very severe, causes a greater flood. The rivers of the southwest attain a violence during these floods that is not readily comprehended until witnessed. Boulders of several feet in diameter are rolled along in the stream bed, producing a noise that may be heard for several miles.

In the mountains of this basin the rains are frequently very heavy, often falling on slopes that are both rugged and steep, thus yielding floods which being shot out from the hills far beyond the ordinary limit of surface flow into the desert, fill up the porous sand and gravel of the river bed as they progress, and from their very nature disappear as rapidly as they began. From 24 hours to a week thereafter will find the bed of the lower portions of the stream again dry at the surface.

This is the general character of the Mojave River. During the summer it flows in places, where the position of the canyon walls or of bed rock force the water to the surface, in a stream of 20 or 30 cu. ft. per sec., rising and sinking on its uncertain journey as it encounters impervious material and finally losing itself in the sand just below the headworks of the Southern California Improvement Co.

The floods that issue from the mountains carry themselves as far out into the plains as their sandy river beds will permit. In addition to these waters are those supplied to the stream perennially and which normally sink at the foothills. These percolate down the channel probably at the rates of from 5 to 20 miles a year, depending on the slope and the character of the voids in the stream bed. It is the water in the voids of the sand and that which percolates in the stream bed that the Southern California Improvement Co. endeavors to obtain.*

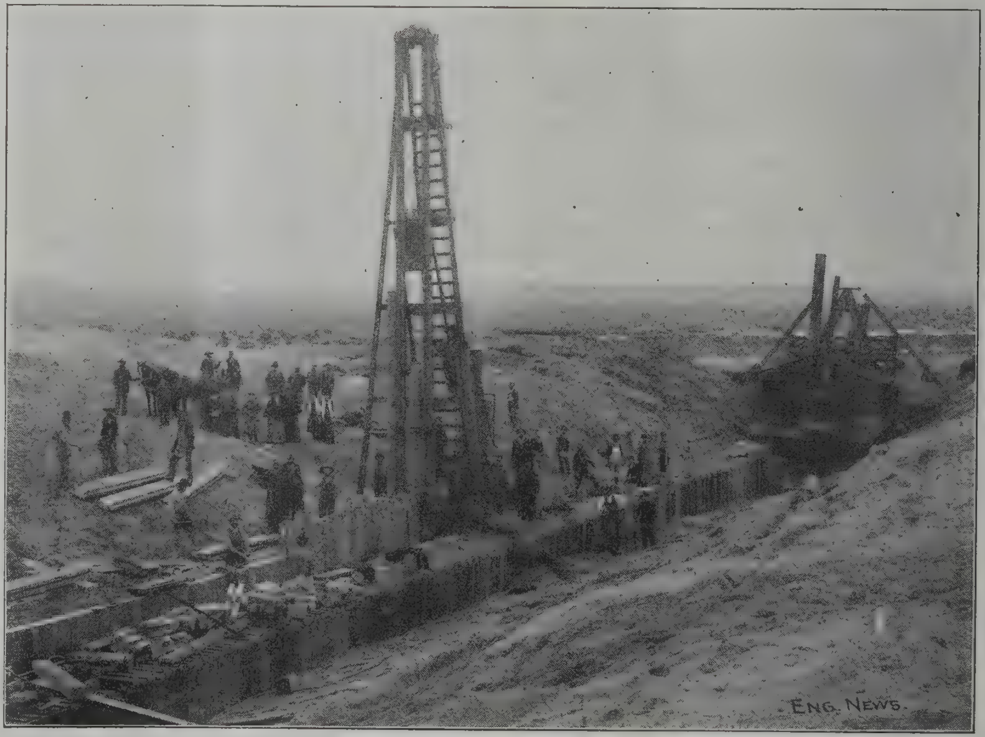

FIG. 2.—VIEW OF DAM AND COLLECTING GALLERY UNDER CONSTRUCTION.

The determining fact in the selection of the point for the construction of the diversion works of the Southern California Improvement Co. was that the bed rock as an impervious stratum was found nearer the surface here than at any other place on the lower portion of the river, and although the river channel is broad and the valley extends in an unrestrained way to the south, from the surface channel, all things being considered, this was chosen as the most feasible place to put in the works of development.

The rock of this locality is favorable to the work. It is a pronounced porphyry and is found in every color. It disintegrates rapidly on exposure to the atmosphere and forms clays on its surface. The exposed rock in the hills is thus melting away into clays, being very soft on top and getting harder as it is penetrated. A foot from the surface the rock is usualy quite solid. As this condition obtains on the side hills next to the river, it is assumed that the clays that are found in much the same condition beneath the sands of the river bed are of the same nature and gradually merge into the porphyry rock, making an ideal condition for the stopping of the underflow of the river with sheet piles, which are here used. The piles are said to be driven from 1½ to 5 ft. into this clay, the latter being covered with a varying depth of river sand. The piling could not have been driven true in case large boulders had been found in the stream bed.

The method of procedure in the construction of this work was to start a canal far enough down in the valley below to permit the water that was developed to flow away from the works as it was encountered. At the point where the canal enters the river bed the conduit is changed into a carrying flume. This is shown as line A B on the map, Fig. 1. This flume is 5⅓ ft. in the clear; the top, sides and bottom are made tight to prevent any escape of the water which has been gathered above. In other respects it is constructed the same as the gathering flume which will be described below. This carrying flume passes through the sheet-piling and into what is called the "well." This is a junction bay into which it is the intention to have all the gathering flumes empty.

The "well" is 10 × 6½ × 6½ ins., and is made of 6 × 8-in. timbers laid flat and bolted together. The bottom is drifted into piling, which are driven into the bed of the river for the purpose of forming a foundation and anchor for the bay; the top is made of the same material, and two large trap doors open through it from above. These doors may be fastened down solidly to the rest of the frame. The top of the well is on the level with the top of the sheet-piling, and is 5 ft. below the bottom of the river bed. The trap door on the top of the well opens into a temporary shaft that extends above the surface of the ground and permits entrance into the flumes. This shaft is made of 2-in. plank and is set on the main well, but is not fastened, so that when the floods come they will roll the shaft away, and the doors of the well being closed the flood will pass over without encountering any obstruction.

---

*As many of the conditions in connection with this work were personally investigated by the writer as was feasible, but much of it is of such a nature that this could not be done.

The well being finished, the channel of the river was next opened along the line B C, Fig. 1, with scrapers, to a depth of about 10 ft., the water developed being permitted to pass out through the carrying flume; This scraper work having been excavated well down into the water-bearing gravels, the gates of the well were closed and the open channel allowed to fill with water. The dredger then floated into place and the excavation continued to the desired depth. It was then floated away and beached, and the gates of the well were opened, which by the drawing off of the water permits of the laying of the flume. This same order was followed in the laying of the carrying flume.

The gathering flume is first constructed and placed and then the sheet-piling driven below the flume (down stream), as show in the view, Fig. 2.

It is the intention to drive a row of piling on the line C B D, Fig. 1. These sheet piles are of the ordinary type, being 3-in. Oregon pine plank, 12 ins. wide, firmly bolted together, the lower end being sharpened to an edge. The lap of the plank is 3 ins., which permits the head being rounded to a diameter of 9 ins. These piles are driven with a 2,200-lb. hammer through the sand and gravel into the clay which is said to cover the top of the porphyry bed rock

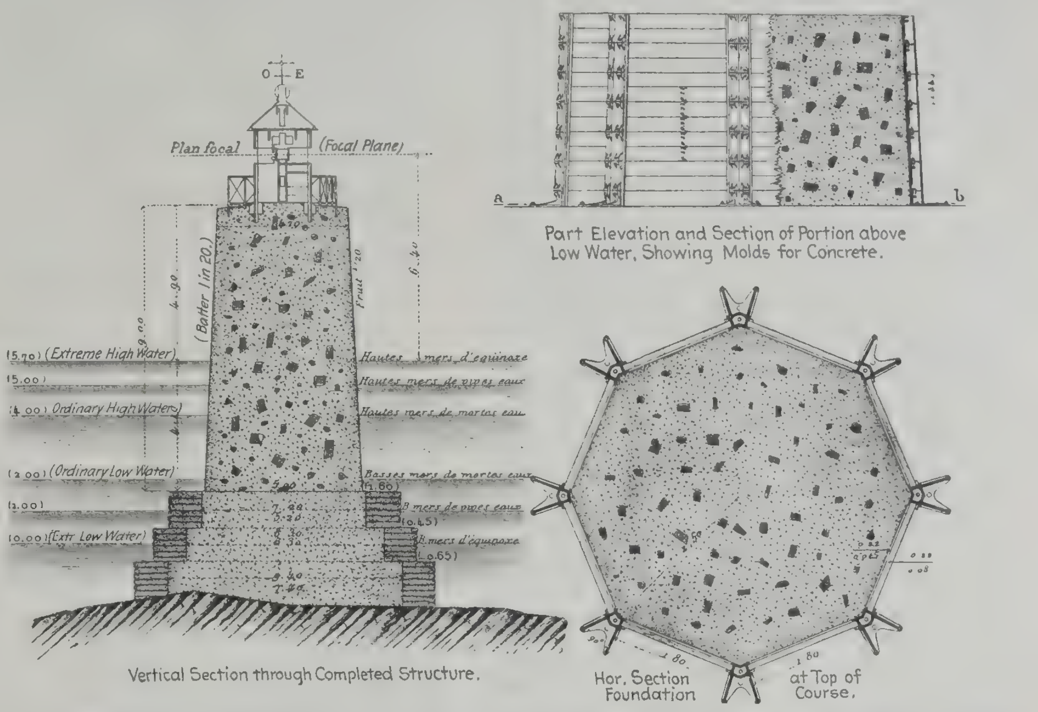
Up to May 1, 1896, the piling had only been driven for about 600 ft. south from the junction bay or well at the center of the channel, as shown by the line B C, Fig. 1. They are sawed off at a depth of 5 ft. below the bed of the stream and below the level where the sand has become stratified. All of the flumes and piling are to be covered with sand, as finished. By this method it is the intention to offer absolutely no resistance to the stream when it is in flood, and in that particular the plan is most wise, for it has been found that in placing the slightest obstruction in a torrential stream bed that obstruction will be subjected to violent attack from both water and boulders. An excavation being made below the obstruction it will be thus undermined and knocked over.

The gathering flume is built from the well 700 ft. south. It is made of 3 × 12-in. Oregon pine plank, except on the top, where they are 4 instead of 3 ins. thick, to support the gravel above. It is built square, 5⅓ ft. in the clear, and in the manner in which timbers are framed for shafting, each being mortised into the other, and all being framed around 6 × 6-in. longitudinal timbers, which are set in the corners inside. A much more convenient form of flume for working purposes after construction, and with no more material in it, would have been 6⅓ × 4⅓ ft.

The bottom of the flume is first made upside down, the plank being nailed on the longitudinal piece, then floated into place and turned over. The sides and top are then built onto it. Openings of ⅝-in. width were left in the sides, and of 1⅛-in. in the bottom of the flume to admit the water. Four 4 × 8-in. sills were placed on the bottom of the cut for the flume to rest on. They were rammed well into the gravel and laid longitudinally.

Numerous water development tunnels have been built in southern California in water-bearing sands and gravels and have been lined by placing lagging on the top and sides on the caps and posts. These posts rest on substantial sills, but frequently no floors are put in them. These tunnels have been successful in obtaining water but they probably lose water by percolation where the grade gets above the water plane. In this case, where the sheet-piling brings the water plane constantly above the flume grade, it would seem that the gathering flume might have been dispensed with. As it is, one-tenth of the bottom is left open, and efforts have to be made to keep these openings clear. The intention of the design was to prevent sand entering the flume too freely and interfering with the flow in other parts. The action of the fine sand in the present case is to work into the openings in small quantities.

It has been found that driving the piling, after the flume was in place and only 2 ft. from it, has been the cause of jamming it out of line and driving the gravel tightly into the openings. In the remaining portions of the channel the piling will be driven as much as 25 ft. from the flume to avoid this undesirable result. The flumes are provided with gates so that they may be kept full of water to prevent rot.



Vertical Section through Completed Structure.

Part Elevation and Section of Portion above Low Water, Showing Molds for Concrete.

Hor. Section Foundation at Top of Course.

SECTIONS SHOWING THE CONSTRUCTION OF A SMALL CONCRETE LIGHTHOUSE AT TROIS PIERRES, FRANCE.

The work of driving the sheet-piling across the river was less than half finished on May 1, the portion B D, Fig. 1, not being completed. It is fair to presume that when the channel is entirely closed to bed rock on either side of the river a greater amount of water will be obtained than a direct proportion of the present amount of water flowing to the portion of the river bed that is now shut off. At the present time there is approximately 7 sec.-ft. of water flowing from the carrying flume.

It is proposed to use this water on the Minneola Valley, which is a desert at the present time, but with the aid of water very favorable results may be obtained in an agricultural line. For the purpose of irrigation a charge of $22.50 per acre for the water right is made and an annual rental of $1.50. The duty of 1 cu. ft. per sec. to 250 acres is made. This is at the rate of $5,625 per sec.-ft. for the water right and $375 annual income from rentals.

There are a large number of mines in this neighborhood, borax, iron, copper, silver and gold being found near here. These mines are paying at the rate of $11.50 a ton for coal. A drop of 100 ft. in the grade of the main canal has been planned for the purpose of developing power which will be offered to the mines and used for general purposes.

Mr. W. E. Robinson is general manager and vice-president of the Southern California Improvement Co. He designed these works and superintended their construction. The work has been well done and is a credit to his ability and energy.

◆

A MONOLITHIC BEACON TOWER, FRANCE.

We illustrate herewith the beacon tower of Irvis-Pierres, at the entrance to the harbor of Lorient, on the coast of France. The execution of this work presented grave difficulties, owing to its exposed situation and the fact that the rock upon which it was to be founded lay about 6½ ft. below the level of the lowest tide, while the extreme rise of tide was 18.7 ft.

As built, the beacon proper is octagonal in form, with a base diameter of 16.4 ft. and a top diameter of 15.4 ft., 29.5 ft. above the base. The foundation was built in three courses, each presenting an offset of 2.8 ft., the total height of the base being 11.8 ft. The first part of the work consisted of clearing the surface of the rock from a heavy growth of seaweed; this was done by divers, and the roots and the finer mosses were then burned by breaking upon them carboys of hydrochloric acid and finally scrubbing the surface with steel brooms and fine wire brushes.

To define the exact position of the proposed beacon, and to guide the divers, a rectangular mast of wrought iron was fastened to the rock by wedges and spikes and bags of beton placed around the base. The center thus made was utilized in building a wall of bags of beton intended to contain the first layer of the concrete base; a light piece of wood attached to a ring encircling the mast was used to fix the position of the inside bags. It was found that the current was not strong enough to stop the divers from working and the state of the sea itself was the only obstacle, this latter depending on the direction and force of the wind.

When the wind was favorable a tug towed to the work a large barge and two smaller boats, containing all the material necessary for one day's work. The beton was made as it was needed, upon the barge, which was moored to four buoys located with the beacon-mast as a center. The beton was mixed during the passage of the plant from the little harbor of Lamar, and in building the encircling wall each sack of beton was lowered from a derrick on the barge in an iron bucket. The divers received this bucket and by opening the bottom deposited the sack in its place. The washing out of the cement was thus avoided. The sacks were made of a somewhat loose material which permitted their contents to unite closely together; and each empty sack made a rectangle of 4 × 5.2 ft., and 11 filled sacks made 1 cu. m. of wall. When this wall had reached a certain height it was filled with beton of the same character as that in the sacks themselves by dumping it from a cylindrical iron bucket with a bottom door.

The proportions for the beton to be used were only fixed after a special study. At high tide certain wooden boxes, 1 m. square on the sides and located near the experimental station at Lorient, were filled with beton. At the following low tide the sides of the boxes were demolished and it was then easy to watch the effect of the sea upon it. This experiment, continued during three months, convinced the engineers that a mixture of broken stone and a mortar rich in cement would give the best results. Ramming the submerged beton was impossible, as this would have led to a complete separation of its elements by the action of the water. On the other hand, with broken stone as a constituent element of the beton, ramming is indispensable to obtain the intimate mixture of the stone and cement mortar. For this reason the first beton experimented with was generally lacking in compactness and impermeability. This difficulty was finally overcome by using material of small dimensions, or a gravel mixed with sand obtained from a beach near Lorient. The beton then adopted had a definite proportion of 500 kilos. (1,100 lbs.) of Portland cement to 1 cu. m. of the gravel; or, about 3 barrels of cement to 1 cu. yd. of gravel. This beton gave excellent results. The experimental blocks showed no interior voids and, thanks to the precautions taken in depositing it, there was no notable deposit of "milkiness" or "laitance" between the several beds. The mass was perfectly homogeneous throughout its height. The completion of the foundation courses required the three summers of 1891, 1892 and 1893, during which time only 54 days were available for actual work. The cost of the foundation work was 18,016 fr. ($3,603.20) for 195 cu. m.; this was equivalent to 84.60 fr. per cu. m., or about $13.00 per cu. yd.

The beacon tower itself was made of the same beton as the foundation, but the work was executed in the dry at low tides. As a matter of some slight economy, large stones were introduced into the beton, as shown in the illustration, the concrete being well rammed around them. The tower presents the form of a trunk of a pyramid with an octagonal base; a form fixed upon as most convenient for the arrangement of the molds to be used. The base is a regular octagon, 16.4 ft. in diameter, diminishing to 15.4 ft. at the top, which is 29.5 ft. above the foundation and about 16 ft. above the level of the highest equinoctial tides. Upon the upper platform of the tower is a fixed light, adapted to the use of mineral oil, placed in a lantern, 5 ft. 3 ins. in diameter, constituting a light of the fifth order.

The molds used in building this tower were arranged as follows: At each corner of the octagon were placed special castings, the first or lowermost one securely anchored to the foundation, and successive sections were then bolted on as the work of filling progressed. These cast-iron sections had a uniform height of 2.44 ft. corresponding to two mold planks of 1.22 ft. each in width; the castings only weighed about 25 lbs. each, so they could be easily handled, and 3 bolts held them in place. The most delicate and important preliminary operation was the exact location of these castings at the eight corners of the tower. But when this was done the filling of the molds with beton was performed with the same bucket used in building the foundation and operated from a mast on the barge, and finally from a mast planted on the tower itself. The tower was built in the months of July, August, September and October of 1894; though in this period there were only 35 days available for effective work. The actual cost of this portion of the work was 3,570 fr. for material used, and 11,786 fr. for labor and all the accessory expenses of execution, including in this sum the original cleaning of the surface of the rock for the reception of the foundation. The tower contained 119 cu. m., and the item cost was 94.30 fr. per cu. m., or about $14.51 per cu. yd. As the foundation masonry, executed under water, cost only $13 per cu. yd., the cost of the tower seems high. But it must be remembered that in building the foundation the same quantity of beton was used each day, as the tides did not have to be considered. On the contrary, work on the tower was executed according to the stage of the tide, and in the beginning only one hour out of each tide was available for work. The workmen and the tug-service were paid for by the day and consequently the general expenses were constant. The total cost of the beacon tower was about 33,000 fr. or $6,600.

Since the completion of the work in October, 1894, the tower has been subjected to storms of exceptional violence. An examination made after two of these storms shows that the sacks of beton about the foundation are securely united together and none have been displaced; they preserve their original form in every detail. It is interesting to note that the foundation is already covered with a great quantity of small marine shells binding the sacks together and forming an excellent protection against the action of the sea.

The above description is prepared and our illustration is reproduced from a paper in the "Annales des Ponts et Chausees."

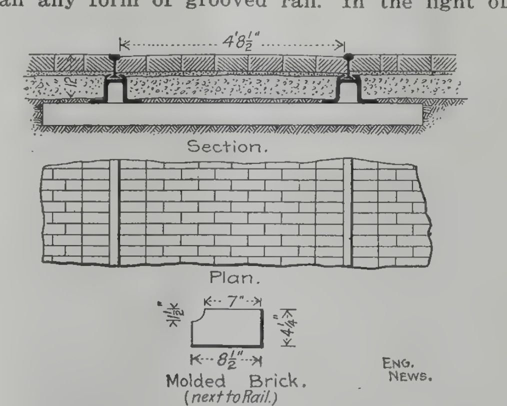
BRICK PAVING ALONG A STREET RAILWAY TRACK.

The city of Cortland, N. Y., is laying a large amount of brick paving this season. The accompanying cut gives a plan and cross-section of an electric railway track, showing the method specified for laying paving next to the rails and the bond adopted for the paving between the rails. It will be seen that the rail is supported on chairs in order to place the tie under the concrete and elevate the rail head to a level with the pavement. That street railway managers prefer the T-rail is well known, but it would seem that special brick forming a groove along the rail head would be better than the method here shown which breaks up the even surface of the street and leaves the inner side of the rail head as an obstruction to traffic. If the paving is laid in the way suggested, as is done in several cases, the T-rail is little more of an injury to the street surface than any form of grooved rail. In the light of these facts it would seem that the statutes and ordinances which have been enacted in various states and cities requiring the use of grooved head rails in the streets might well be reconsidered.



An Electric Railway Track in a Brick Paved Street at Cortland, N. Y.

The work at Cortland is being carried out under the direction of Mr. Wm. B. Landreth, M. Am. Soc. C. E., as Engineer-in-Charge, and Mr. Walter L. Webb, Assoc. M. Am. Soc. C. E., as Assistant Engineer.

SIX TWIN-SCREW STEAMERS for the North German Lloyds' Steamship Co. have been launched at Stettin, Germany. Two of them are to be express steamers and four are intended for the regular passenger and freight service of the company between Bremen and New York. The dimensions are as follows: Length 525 ft. between perpendiculars, or 550 ft. over all; 60 ft. beam, 34 ft. deep, 10,000 tons register, and approximately 20,000 tons displacement, with a draught of 28 ft. The cargo space, including the steerage decks, shows a capacity of 11,000 cu. meters or 10,000 tons measurement. The cabins contain accommodations for 100 first-class and 76 second-class passengers, and 2,300 passengers can be carried on the steerage decks when not needed for cargo. The fore part of the steamer is provided with a turtle-back deck, 80 ft. in length, as a protection against the high seas of the Atlantic, and over the after part there is a poop 66 ft. long. Besides the double bottom, extending the whole length of the steamer, the vessels are divided by twelve transverse bulkheads, extending to the upper deck, into thirteen water-tight compartments. The motive power consists of two quadruple-expansion engines, which in three of the steamers will develop 7,000 I. HP. with a speed of 14 knots; while the others will have engines of 8,000 I. HP., resulting in a speed of 15 knots.

◆

THE STRAIGHTENING OF A CHIMNEY STACK at the brick and tile works of the Standard Concrete Mfg. Co., Earnest, Pa., was recently accomplished under the supervison of Mr. B. W. Seamans, the company's superintendent. The stack is 122 ft. high, 11 ft. square at the base, tapering somewhat at the top, and weighs 400 tons. The walls are 36 ins. thick. The top was found to be leaning 45 ins. from a vertical line. To sink the side 4½ ins., 10½ ins. of brick work was removed from the foundation on three sides. As the bricks were removed square blocks of wood were inserted, one after the other, until three sides of the stack rested on the blocks. Between the blocks, supporting the stack temporarily, substantial brick piers 6 ins. high were built, leaving a space 4½ ins. between the top of the piers and the bottom of the undermined brickwork. The blocks were then set on fire and all were kept burning briskly. If one burned faster than the others the fire on that particular block was checked, so that all were made to burn uniformly, and as the blocks were being reduced to ashes the stack slowly righted. As the top gradually swung back through the 45-in. arc, small fissures appeared near the base. Into every crevice a steel wedge was driven, maintaining the solidity of the walls. The entire work consumed one day, and the reduction of the wooden blocks to ashes required an hour.

◆

A 24-IN. GAGE RAILWAY is probably to be built as an experiment by the government of the colony of Victoria, Australia. The line will be from Wangaratta to Edi, 24-in. gage, laid with 20 or 24-lb. rails, with engines of about 80 HP., capable of hauling a load of 250 tons on the level, with a passenger car seating 30 passengers, the weight of the cars being 6 tons each.

◆

A BOILER EXPLOSION occurred at a grist mill at Harrodsburg, Ky., Aug. 29, and several men were hurt and scalded.

RAPID WORK IN RAISING A WRECK was accomplished in the case of the steamer "Rosedale," which was sunk in 16 ft. of water, by a collision in the East River, New York, on Sept. 3. The Chapman Wrecking Co. had the vessel raised within 24 hours after the accident. The "Rosedale" measures 216 ft. over all, 34 ft. beam, 10 ft. draught.

◆

CHAINLESS BICYCLES, in which two pairs of bevel gears are used instead of the chain, are reported to have proved their superiority over the present style of wheel in a test, in which a wheel was run 39,000 miles without adjustment or appreciable wear. Dynamometer tests also show that the bevel gears run with less friction than the chain. It is stated that one of the largest manufacturers will soon put these wheels on the market. An obstacle to their rapid introduction is the time required to construct the machinery necessary for turning out the bevel wheels which must be mathematically accurate in form.

◆

THE NEW YORK & NEW JERSEY BRIDGE CO. held a meeting at 214 Broadway, New York city, last week, at which Gen. J. S. Clarkson was elected President; Louis Windmuller, Vice-President, and Charles H. Swan, Secretary and Treasurer.

◆

FOR THE NORTH SEA AND BALTIC SHIP CANAL a revised tariff of charges on shipping went into operation on Sept. 1. Under the old tariff vessels up to 600 tons net were taxed 60 pfennings, or 15 cts. per ton, and vessels above that tonnage, 40 pfennings, or 10 cts. per ton. Under the new tariff the 10-ct. rate begins with vessels of 400 tons; above 600 tons, the tax is 30 pfennings, or 7½ cts., and beyond 800 tons it is 20 pfennings, or 5 cts. per ton. For vessels empty, or in ballast, the tax is 20% less than the above rates. Besides the above dues sailing vessels using the regulation tugs will be charged as follows: For the first 200 register tons net, 10 cts. per ton; for every additional register ton, 7½ cts. From October to March the charges for tugs will be increased 10%, but these charges include compensation for the use of the entire working arrangement of the canal and for the services of pilots between the ends of the canal.

◆

THE MANCHESTER SHIP CANAL CO. has sent its general manager, Mr. Marshall Stevens, to this country to induce the transportation companies here to make more use of the canal. Mr. Stevens has issued a circular letter setting forth the apparent advantage, at least, of shipping direct to Manchester instead of via Liverpool. He claims that with no reduction upon inland freight in America and with an even sea rate there will be an average saving on the whole New York cargo of 7 cts. per 100 lbs., or $1.56 per ton in favor of Manchester; and $1.17 per ton saving on the New Orleans cargo. He does not explain where this saving comes in, except to say that delivery by cart to destination is included in his figures and that one week is allowed at the Manchester docks for the removal of freight from the quay sheds, as compared with 3 days at Liverpool.

◆

CAST-IRON PROJECTILES are soon to be ordered by the Ordnance Bureau of the War Department, about $50,000 being expended on shells and shrepnel. The latter will be bought for use in the 3.2 and 3.6-in. guns, the projectiles to be fitted with 15 and 28-second fuses. The cast-iron shells are for the siege and seacoast guns; 500 shells of the 7-in. 500-lb. type will be bought for siege projectiles. The shells for use in the seacoast guns are as follows: 100 8-in., 100 10-in., 100 12-in., 100 12-in. 800-lb. mortar, and 50 12-in. 1,000-lb. mortar shells.

◆

ONE OF THE LARGEST GUNS designed in this country is the 16-in. gun which the Watervliet arsenal is now getting ready to build. The United States has built two of larger caliber for its coast defences, but they were old-fashioned 20-in. smooth-bores, 20 ft. long, with a range of between five and six miles. The new gun will be 49.67 ft. long, will have a range of 16 miles and be able to penetrate 27½ ins. of armor at a distance of two miles. The gun will weigh 125 tons, and it will throw a solid armor-piercing projectile weighing 2,370 lbs. The great trouble so far found in the construction of guns of such size has been that they "drooped" at the muzzle after being fired a few times. The Ordnance Board, however, believes that it has succeeded in overcoming this defect. The maximum diameter of the breech of the new gun will be 62 ins., and the diameter of the breech opening 20 ins. To fire this gun will require a charge of 1,060 lbs. of the usual brown prismatic powder.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week occurred, Sept. 7, at Taswell, Ind., on the Louisville, Evansville & St. Louis Consolidated R. R. The wrecked train was an excursion from St. Louis. The baggage car and three coaches jumped the track and rolled down an embankment. Ten people were injured, two fatally.

◆

A THRESHING ENGINE BOILER EXPLODED near Sanilac Center, Mich., Sept. 2. It was carrying 100 lbs. pressure at the time. Three men were killed and two injured. Near Charleston, W. Va., on Sept. 2, a saw mill boiler exploded, killing two men and injuring two others.

◆

A FALLING WALL killed eleven firemen at Benton Harbor, Mich., Sept. 6. The Yore Opera House, a four-story brick building, was not discovered to be on fire until the flames had made considerable headway. The wall fell almost as soon as the firemen arrived.

◆

PROPOSALS FOR THE READING SUBWAY (for the depression of the Philadelphia & Reading R. R. tracks) at Philadelphia, were opened Sept. 1, the bidders being Ryan & Kelly, E. D. Smith & Co., P. H. Flynn & Co., Sullivan Bros., Mason, Hoge & Co., and R. A. Malone & Co. The tunnel will extend from 22d St. to Tavey St., 2,710 ft. In this distance there will be 13 openings in the center of the newly-made street. Each opening in the center of the roadway will be surrounded by a stone coping 3 ft. high, over which twining vines will grow. Outside of this will be a plot covered with trees and shrubs, and surrounded with a highly ornamental picket fence. Each plot will take up a space 10 × 48 ft., and in the narrowest part there will be an asphalted roadway on either side, 27 ft. wide, giving a street on either side at least as wide as Chestnut St. The next contract covers that part of the subway beginning east of 22d St. and running to the grade at 30th St., and includes all of the tunnel work and part of the open subway. The original plan required the erection of fan houses by the city for the purpose of expelling the foul gases from the tunnel, but this has been done away with and the new plans call for openings in the tunnel which will be a great saving in the cost of construction. The work has been described and illustrated in our columns.

◆

THE TAMALPAIS MOUNTAIN RAILWAY was opened Aug. 26. The line starts from Mill Valley, Cal., and rises 2,300 ft. in a straight distance of two miles, although the railway is 8¾ miles long, with grades of 5 to 7%. The line is a very winding one, composed mainly of curves and loops, the sharpest curves being of 72 ft. radius.

◆

A RECORD FOR TRAINS RUNNING ON TIME is claimed by the Chesapeake & Ohio Ry. for its four limited trains running between Washington and Cincinnati, Each train covered the distance of 599 miles 122 times during the months of March, April, May and June, and the four trains were on time 463 times out of a possible 488, or 95%.

◆

AIR MOTORS WERE SUCCESSFULLY TESTED on the night of Sept. 3 on the boulevard line of the Third Avenue Railroad in New York. They ran from the Fort Lee ferry across town, back to Tenth Ave. and up the heavy grade on that avenue to Fort George. The cars were stopped and started up and down on the steepest grades.

◆

AN AIR MOTOR capable of pulling a train of five cars is shortly to be tested on the Sixth and Ninth Avenue lines of the New York elevated railroads. The American Air Power Co. which is to furnish the motor, has leased a building at Greenwich and Rector Sts., where the plant for compressing the air is being erected. A pipe will be run from the motor house to the Rector St. station, where the motor will be charged. The motor is being built at the Rome Locomotive Works, and is to be completed by Nov. 1.

◆

THE "FRAM'S" HIGHEST LATITUDE, says Capt. Sverdrup, in his detailed account, was 85° 57′ North, in 66° East longitude, reached on Oct. 16, 1895. From this point the "Fram," tightly bedded in the ice, drifted southward. Aside from the fact that this expedition reached a point nearer to the North Pole than any preceding it, is the remarkable behavior of this remarkable ship. Capt. Sverdrup, who succeeded to the command after Capt. Nansen left the ship on his expedition over the ice, says that though the ship was repeatedly subjected to enormous pressure from the ice, she was safely and quietly lifted up without undue strain; sometimes being lifted 6 to 9 ft. several times a day. He reported the expedition as an easy one, resulting in no damage to the ship or to the men.

◆

THE PAVING OF CITY STREETS was referred to in a paper on "Highway Legislation," read before the American Social Science Association, at Saratoga, on Sept. 3, by Prof. Francis Wayland, of Yale. For cities he advocated compelling the street car corporations to pay for keeping a certain space on each side of, as well as between, their rails in good order. This is only equitable, because by diminishing the amount of room which can be used by vehicles they add greatly to the wear and tear of the remainder. It was, moreover, suggested that a tax should be levied on vehicles in proportion to the amount of injury which they were capable of doing in their daily use. There seemed no justice in calling on abutter to pay a considerable part of the expense of repairing a street which would have needed almost no repair but for the damage caused by heavy carts. If the amount of this "wagon tax" were used exclusively for street repairs it would go far toward a reasonable solution of the problem. This expedient has been adopted in other countries with good results.

◆

THE STEEL ARMORED CRUISER "BROOKLYN," in her trial trip of Aug. 27, made an average speed of 21.92 knots in a run of 83 knots, and passed over part of the course at the rate of 22.90 knots per hour. She made the run with a boiler pressure of 160 lbs. and an average of 138 revolutions per minute of the screws, with a maximum of 140 revolutions. By her performance she is claimed to earn a bonus of about $350,000 for her builders, the Messrs. Cramp, of Philadelphia. Her contract speed was 20 knots per hour. The cruiser "New York," on her trial trip, made an average of 21 knots; the "Minneapolis" made 23.073 knots; the "Columbia" made 22.81 knots, and the "Olympia" made an average of 21.69 knots per hour.

◆

THE WIRE FOR THE NEW SUSPENSION BRIDGE over the Ohio River between Cincinnati, O., and Covington, Ky., is now being delivered, and the work of stringing the wires and making the cables will soon be commenced. The wire is of No. 6 gage, and is delivered on large spools.

◆

THE NEW BROOKLYN TIMBER DRY-DOCK, now under construction at the Brooklyn Navy Yard, is to be completed for the government about Nov. 30, next, by the present contractors, T. & A. Walsh. This dock was contracted for originally with John Gillies, and it was to cost $575,000. After no practical progress had been made in two years, it was taken from him and on April 30, 1895, it was awarded to the above contractors, and will now cost, complete, about $650,000. The general dimensions are as follows: Length, 658 ft.; width, 64 ft.; width at entrance, 105 ft.; mean draft at high water, 28 ft. More detailed dimensions are as follows:

	Ft.
Length on coping level	560
Length inside head to inner sill	580
Length inside head to outer gate sill	600
Length inside head to outer end of table	625
Length on floor head to inner abutment	516
Length on floor head to outer gate sill	556
Width on coping on head	94
Width on coping on body	151
Width on coping at abutment	105
Width on coping at entrance	105
Width at entrance on high water line	100
Width of coping at outer end of table	154
Width on floor of dock at head	27
Width on floor of dock at head angles	64
Width on floor of dock in body	64
Width on floor of dock at abutment	64
Width on floor at inner abutment	70
Width on floor at outer end of table	116
Depth from top of coping to mean high water	5
Depth from top of coping to inner abutment floor	33
Depth from top of coping to working floor of dock	35

◆

AN INTERESTING CASE OF CORROSION of the metal of marine engines was described at the recent meeting of the Institution of Mechanical Engineers at Belfast, Ireland. A steamer loaded with "burnt ore" was sunk off the coast of Scotland, and was under water for a week. When the vessel was again floated the machinery was found to present an extraordinary appearance, all wrought iron work being deeply corroded, and planed cast iron being so soft as to be easily cut with a knife. As engines are generally little injured by submergence, even for a considerable time, it was evident that there had been some unusual chemical action. The source of this was found in the cargo, burnt ore being the residue from the manufacture of vitriol from sulphur pyrites, and usually containing sulphates of copper and iron. These salts would react on the chloride of sodium of sea water to form sulphate of sodium and chloride of copper, either of which in solution dissolves wrought iron or cast iron.

◆

AN EXHIBITION OF MACHINERY will be held in Munich in 1898. American manufacturers have been invited to participate, according to a letter from U. S. Consul Steiner to the Department of State.

THE SEWERAGE AND SEWAGE DISPOSAL SYSTEMS OF PLAINFIELD, N. J.

By Andrew J. Gavett, Constructing Engineer.

The city of Plainfield, N J., is situated in the western corner of Union Co., hemmed in on two sides by the counties of Somerset and Middlesex. On the Somerset Co. side, only separated from the city by a narrow brook, is the borough of North Plainfield, and its interests are identified in many ways with those of the city.

The population of Plainfield is now about 13,500, that of North Plainfield 3,500. Such a large proportion of the residents of both places are New York business men that the chief occupation of the people is said to be "going to New York."

An excellent water supply system, pumping from wells in the eastern part of the city to a stand-pipe 140 ft. high, has been in use a number of years, but this has only emphasized the urgent need of a system of sewers. The poorer buildings are supplied with outhouses having leaching vaults, and cesspools, also leaching, for sink wastes. The better class of buildings generally have complete and often costly systems of plumbing, but all draining into cesspools on the premises. These were emptied from time to time by "odorless" excavating carts, and the expense of this work was no doubt very much greater than all the extra taxes and interest on the assessments for the sewerage system will be.

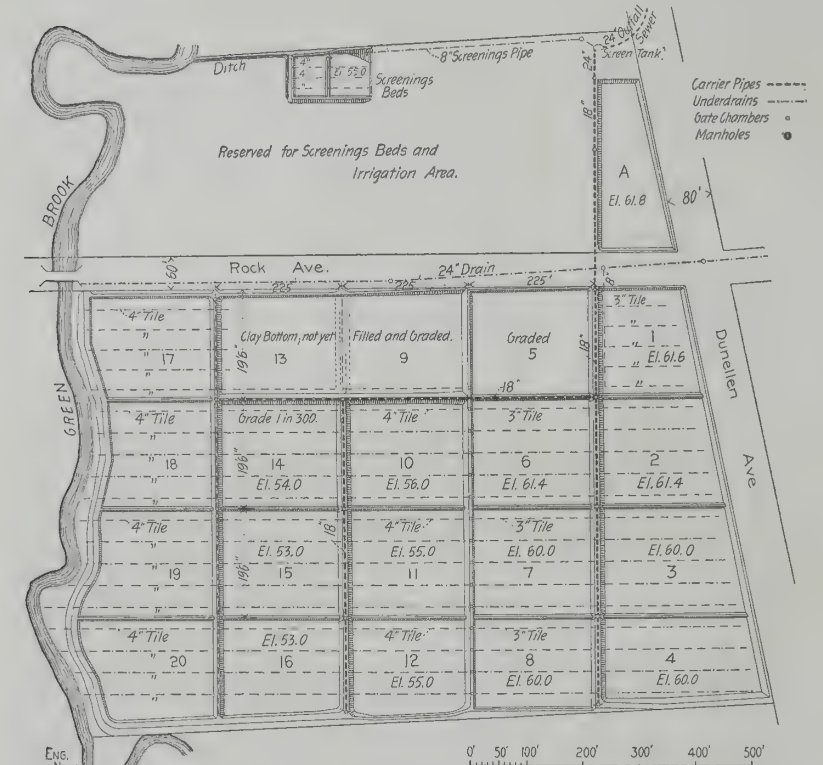

FIG. 1.—PLAN OF SEWAGE DISPOSAL AREA, PLAINFIELD, N. J.

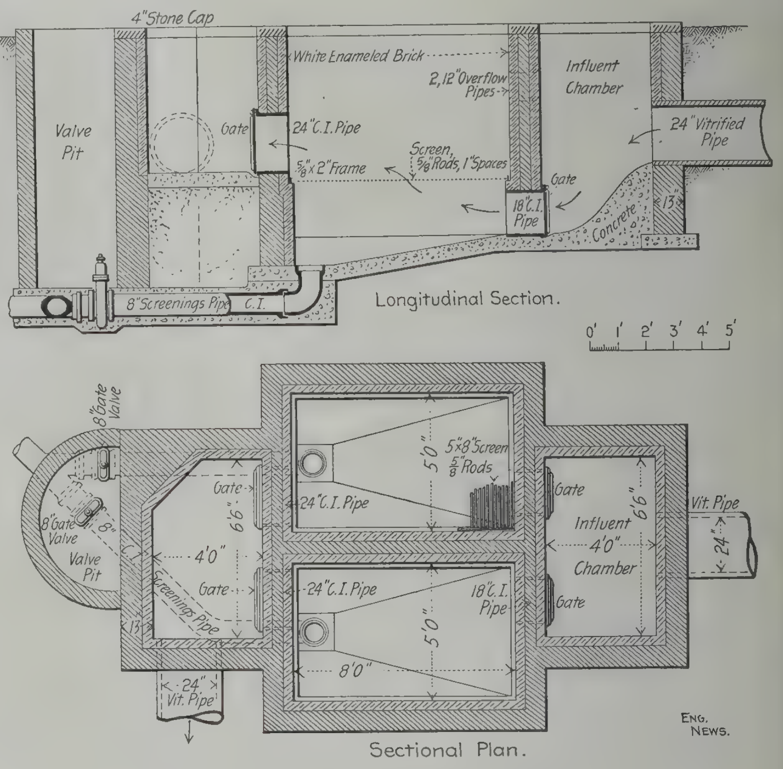

FIG. 4.—DETAILS OF SCREEN CHAMBER.

Topography.

Geologically and topographically, Plainfield has the ice age to thank for her formation. From 40 to 70 ft. below the present level of the city is the Triassic red sandstone and shale; across the eastern end of the city stretches the terminal moraine of the ice sheet, while the underwash from the glacier forms the site of the city. These details are given as they indicate with considerable exactness the character of the material encountered in the construction of the sewerage system and that of the disposal beds as well. The latter are situated in that part of the city farthest from the moraine.

Sewer trenches in the moraine disclose an unstratified mixture of clay, gravel, hardpan, and occasional large boulders. Going west, and descending, a coarse gravel is first found, then stratified sands and gravel, followed by sand alone. The city is underlaid by a flowing sheet of water of great purity and abundance, which furnishes the water supply of the city. At the pumping station the surface of the water is 18½ ft. below the surface of the ground, and it falls toward the southwest at a rate of about 1 in 300, the average inclination of the surface of the ground. At Grant Ave. and Front St. the water was found just below the sewer at a depth of 4 ft., and in the 14-ft. cut at the corner of Central Ave. and Eighth St. the water was also found a few inches below the sewer. But in Ninth and Richmond Sts. the sewer grade was from 6 to 24 ins. below the water level, and the very free flow of water, coming through the open sand and gravel, caused the contractors considerable difficulty and delay.

In all other parts of the city, however, the conditions encountered were extremely favorable, the material being dry and easily handled, no sheeting being required in the more shallow trenches. These conditions explain the very low prices at which the different contracts were let.

Preliminary Work.

The first move for sewers which yielded practical results was made in 1892, when a committee, composed of representative citizens and members of the common council, was appointed by the Mayor, Mr. Alexander Gilbert.

After a thorough investigation and discussion of various methods of disposal, including the popular one of emptying into the Raritan River (for which surveys were made for the committee by Mr. F. A. Dunham, C. E.), the committee reported the estimated cost of several methods of disposal, favoring the plan of intermittent filtration. The report, which included profiles and estimates for the various schemes under consideration, as well as proposed methods of assessment and the providing of funds for the prosecution of the work, was presented to the common council on March 6, 1893, and adopted.

After a careful investigation by the Corporation Counsel, he advised proceeding under the Act of April 7, 1890, which directs that upon the petition of the owners of three-fifths of the real estate valuation of the city, the council shall be empowered to proceed with the construction of a sewer system, issuing, from time to time, temporary obligations of the city in payment for the work, and when completed, commissioners shall be appointed, whose duty it shall be to assess the benefits upon the property benefited, and the excess shall be assessed upon the city at large, and for this excess, bonds shall be issued.

On April 4, 1893, the council decided to proceed under this act, and the work of securing the signatures of the owners of a sufficient valuation was begun. Volunteers made house to house visitations, with copies of the assessor's lists of property-owners, through the remainder of the year 1893 and well into 1894, before the requisite amount was secured.

A general ordinance, specifying all the streets in which it was supposed that sewers would be required, was adopted by the common council on July 25, 1894. Pending the passage of this ordinance, considerable work was done by Mr. George H. Frost, of the sewer committee, in planning the routes for the main sewers, and preliminary levels were run for this purpose by Mr. F. J. Hubbard.

At a meeting held Aug. 6, 1894, the following appointments were made: Committee on Sewers, Messrs. George H. Frost, E. N. Erickson,* S. A. Ginna; Consulting Engineer, F. W. Farquhar, of New York; Constructing Engineer, A. J. Gavett; Assistant Engineers, F. J. Hubbard and H. C. Van Emburgh.

Plans were at once prepared on the lines laid out by Mr. Frost, and on Sept. 10, 1894, the first contract for 5.2 miles of sewers, mostly mains, was let. The first work was begun on Sept. 24, and prosecuted until stopped by cold weather on Dec. 24. During the progress of this work, levels were run over the entire city and a general drainage plan, with profiles, was completed, showing the location and grade of a complete sewer system.

All storm water is excluded from the sewers and flushing is provided for by automatic flush tanks at the head of each sewer. The surface water is carried in the gutters of the streets, directly to the two brooks, or to storm sewers emptying into them. Other storm sewers are planned for future construction, but not many are required, and they will be short ones, from 12 to 24 ins. in diameter. The two brooks are named Green and Cedar, and flow through the entire length of the city, about ¾-mile apart.

Plans for Disposal.

During the winter, the matter of sewage disposal was taken up for final settlement, and estimates of the cost of the various plans which had been under consideration were submitted by Consulting Engineer Farquhar, with the result that all schemes for reaching tidewater were abandoned on account of the great difficulties involved, and the danger of legal complications.

This narrowed the question down to the choice of one of two locations for the disposal beds. One was near Sebring's Mills, a mile below Dunellen, the other in the western corner of the city, 2½ miles nearer the lateral sewer system than the former. Although the Sebring's Mills location possessed a number of advantages, no action could be taken toward securing it for disposal purposes without the consent of the authorities of Piscataway Township, and this consent being refused, the Plainfield site was necessarily decided upon.

---

*Upon Mr. Erickson's retirement from the council in December, 1895, Mr. J. B. Dumont succeeded him as a member of the committee on sewers.

The land finally selected lies at an elevation of from 50 to 72 ft. above mean sea level, so that most of the city can be drained to it without pumping. For the most important outlying district, the Cedar Brook Valley, a system has been designed for future construction, draining to a pump well near the junction of Plainfield and Pemberton Aves., from whence it is proposed to raise the sewage by automatic, electric pumps, through a 10-in. cast-iron force main, 1,000 ft. long, into a gravity sewer at Grant and Sherman Avs.

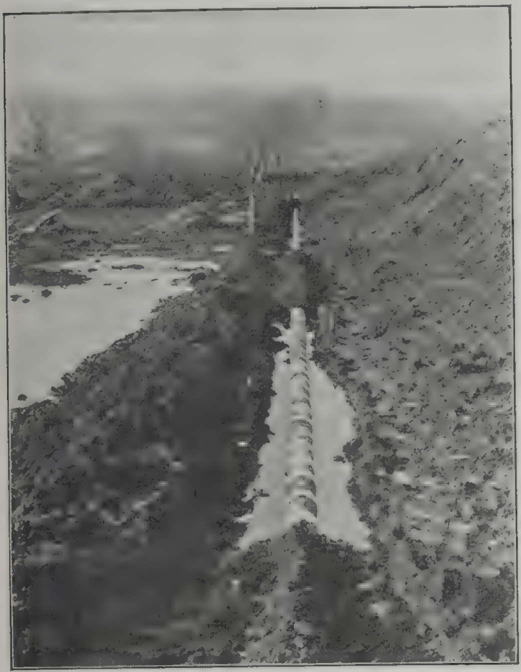

Fig. 2.—View of 4-in. Underdrain in Bed No. 10, During Construction.

Grades.

In order to drain the largest possible area to the disposal beds by gravity, the main sewers have been designed with minimum self-cleansing grades, as follows: For 24-in. sewers, 1 in 1,200; 18-in., 1 in 900; 15-in., 1 in 750; and 12-in., 1 in 600. The 10-in. sewers, and a few of the 8-in. have grades of 1 in 400, but the most of the 8-in. laterals have inclinations of 1 in 300 or more.

Outfall Sewer.

The main outfall sewer is 7,726 ft. in length, from Grant Ave. and Third St. to the screening tank. It is constructed of 24-in. vitrified pipe 1⅝ in. thick, laid on a grade of 1 in 1,200. The greatest depth of cut was 18½ ft., and a length of 2,540 ft. was over 16 ft. deep. At one point it was but 4 ft. deep.

Wherever the cut was less than 5 or more than 15 ft. a concrete foundation and backing was used. A bed of 4 ins. of concrete was first laid and the pipe was then bedded in stiff mortar; when correctly graded and lined, concrete was rammed under and on each side of the pipe. After the concrete had set, the inside joints were cemented on the bottom and more than half way up each side.

Some difficulty was experienced in excavating the trench in the deep cuts, as the sand dried so quickly that it ran out under and between the sheeting planks, loosening the cross braces and causing a cave-in several times, but without serious results. No water was encountered, and where the sheeting was carefully done, the work was ideal for cleanliness and comfort.

Main Sewers.

At Grant Ave. and Third St. the north and south mains enter the outfall sewer. They are respectively of 15 and 18 ins. diameter and the cuts run from 4½ to 14 ft. deep. After traversing circuitous routes and separating some 3,300 ft., they nearly meet again, as 10-in. sewers, on Richmond St.

Lateral Sewers.

The streets running transversely to the main sewers are almost level, and in the center of the city the blocks are generally about 300 ft. square. In order to avoid using an excessive number of flush tanks, which would have been necessary otherwise, many of the cross sewers are continuous for several blocks, crossing the other sewers without connecting.

The necessity of providing sufficient clearance for the different crossings required some sewers to be deeper and others more shallow than the usual depth of about 7½ ft. A 6-ft. length of cast-iron water pipe was used for the upper sewer at all crossings, to prevent settlement.

The least depth of sewers was generally at the flush tanks, in some cases slightly under 5 ft.; the greatest depth, except on the outfall sewer, was 14 ft.

The lines and grades of all sewers were so established that a clear line of sight may be obtained through every part of them, by sighting from one manhole to another, or from manhole to lamphole.

The establishment of this full bore line of sight was one of the requirements of the contracts, but the contractors really had very little to do with securing it, as the inspectors handled the grade rods and plumb lines and were made responsible for accurate work.

Y-Branches and Extensions.

Four-inch Y-branches were located at the most convenient point for each building and wherever else it was thought they would ever be needed, the distances apart varying from 10 to 75 ft. Where the sewers were deep, an extension connection was constructed, consisting of an eighth bend, turned upward, supported by a 12-in. brick pier, with a 2-ft. length of 4-in. pipe added. On the outfall sewer, where the depth would allow, 6-in. T-branches were used on the 24-in. pipe. They were turned upward and were surmounted by a 6 × 4-in. double Y-branch, the branches being turned toward the sides of the street. As the depth increased, lengths of 6-in. pipe were used to raise the double branch to a nearly uniform depth below the surface. In the more shallow cuts, 4-in. Y-branches were used.

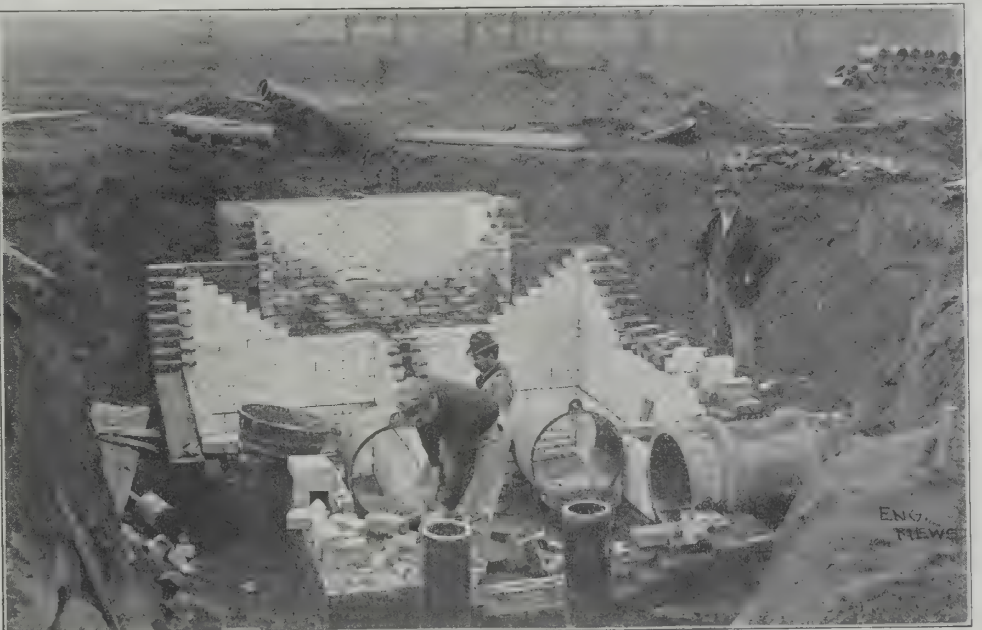

FIG. 3.—VIEW OF SCREEN CHAMBER AT DISPOSAL AREA.

Flush Tanks.

Every lateral sewer is provided with an automatic flush tank at its upper end (except where the sewers are soon to be extended) and little or no hose flushing will probably be needed after the house connections are generally made. The flush tanks are 43 ins. in diameter and of 150 gallons capacity. At first they were set to discharge once in 12 hours but they are now regulated for emptying once in 24 hours. The siphons are of three kinds, Rhoads-Williams, Miller and Van Vranken. A lamphole is constructed adjoining the flush tank and is connected with it by a 6-in. pipe. It is believed that, with occasional inspection, the flush tanks can be trusted to do their work with more certainty, regularity and economy than could be obtained by any system of hand flushing.

The regularity of discharge of the flush tanks is being tested by suspending a "Bristol" counter in the neck of the tank, with a wooden float suspended from the arm. This registers each time the siphon discharges and indicates any failure of the tank to work properly. It will also give assurance to the water company that the tanks are not using more water than is agreed upon. The city pays for the water at the rate of 10 cts. per 1,000 gallons, or about $30 per month at present. In case any flushing with fire hose is needed, it is paid for at the rate of $1 per hour.

In order to ascertain the need and efficiency of the flush tanks, some of them have been shut off for four or five days, and then, when they were turned on again, the flow in the next lower manhole was observed. This experiment showed that the sewers would not keep clean at their upper ends without flushing, as the stream came down black with deposits; also, that the flush-tanks obviated the difficulty, for the last part of the flow ran clear.

It is probable that flushing by hand at considerable intervals would serve to keep the sewers in condition for use, but with disposal beds within the city limits, and in close proximity to dwellings, the periodic washing out of decomposed matter from the sewers would be highly objectionable.

Manholes.

On the main sewers, manholes are placed at all junction points and at all changes of direction or grade, and in general, at distances of from 400 to 500 ft. apart. On the lateral sewers this distance is increased to about 700 ft., lampholes being placed at intervals of 200 to 300 ft. between the manholes. Junction manholes were made 4½ ft. in diameter and intermediate ones 3½ × 4½ ft. in plan. The walls were carried up plumb 3½ ft. and then drawn in to a 2-ft. neck in the next 2½ ft. The walls were 8 ins. in thickness, except where the manholes were over 12 ft. deep, when the thickness was increased to 12 ins.

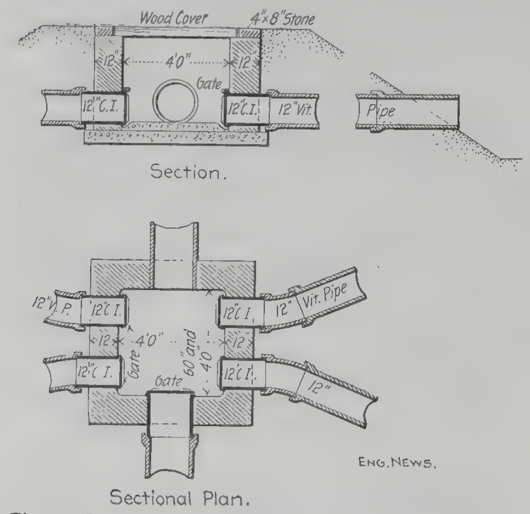
Each lateral sewer, where possible, has a drop into the main sewer equal to the semi-diameter of the latter. Where underdrains were laid with the sewers, an inspection opening was left over the drain in each manhole, the opening being in the platform at one side of the sewer. Stone covers are placed over the openings, and will be cemented on should it be found necessary.

Provision is made for turning the underdrain water into the sewer for flushing purposes, by plugging the drain below the inspection opening and allowing the water to flow through a side opening, into the sewer. When not used for flushing, the underdrain water empties, through two outlets, into Cedar Brook.

Underdrains.

Underdrains are laid in East Ninth and Richmond Sts., in part of Watchung Ave., and in most of the Netherwood district. The sizes are from 3 to 6 ins., with a short section of 8-in. outlet pipe. Hub and spigot vitrified pipe was used for the larger sizes, and agricultural tile for the 3-in. and most of the 4-in.; the underdrains were generally laid 9 ins. below the sewer, and the same distance to the left (going up the sewer).

The drains in the Netherwood section are doing good work, but those in the Cedar Brook Valley are entirely submerged in the ground water every spring, and then only serve as outlets for the Netherwood drains.



Section.

Sectional Plan.

Fig. 5.—Details of Distributing Chambers at Disposal Area.

Materials.

All pipe used in the sewers was from the Ohio Valley, but Akron pipe is being largely used for the 4-in. house connections. All the pipes were in 3-ft. lengths except the 4 and 24-in., which were 2 ft. long.

A careful inspection of the sewer pipe was made at the car while it was being unloaded, and a large quantity was rejected, much of it for crookedness. A regular inspector was detailed for this work, and the payment for pipe was made by the contractor on his reports.

"Hoffman" and "Newark" Rosendale cements were used for all work, and gave entire satisfaction. The specifications called for a cement equal to the "Hoffman" Rosendale, and the contractors decided to use this cement. As its quality was so well known, it was not thought necessary for the city to purchase a cement testing machine, but as a check on the contractors, the constructing engineer had briquettes made occasionally in a standard Riehle mould, and broke them on his own machine, a frame with two levers and 100-lb. spring balance, testing up to 500 lbs.

The cement was used neat, mixed to a stiff paste, for jointing the pipes, and 1 to 1 for mortar for brickwork. Wherever the sewers have since been uncovered, the joints have been found hard and in good condition.

Pipe-laying.

As each pipe was laid, the grade was given by the inspector, using a grade rod with iron shoe reaching into the pipe. A light grade line (braided fish line) was stretched tightly between boards clamped on iron posts. The grade was marked by the engineer on these posts, levels being run each day for the purpose. The iron posts were about $1\frac{1}{2} \times \frac{1}{4}$-in. in section and ordinary cast-iron clamps were used; they were found more convenient than wooden posts, being easily driven and much less liable to wedge off the banks of the trench. They are easily marked with a slate pencil or piece of roofing slate. The inspector kept the pipes in line by plumbing down from the grade line, which was centered on the boards by measuring out from the 4-ft. offset stakes.

A gasket of jute was placed around the spigot end of the pipe before it was lowered into the trench, and the jute was calked into the joint before the latter was cemented. Unless the work was watched, the jute would not be calked into the joint at all, and the cement would be merely beveled over the outside. The other extreme, of having the gasket too small, was also to be guarded against, the general tendency being to use too little jute. The joint room would then be very large on top, sometimes allowing the jute to slip off the end of the pipe and the cement to intrude. The cement was applied to the joints with rubber mittens, being pressed well into the bells, leaving a bevel of cement on the outside.

After a section was cemented, each joint was examined by the inspector, who was also required to see that the earth was solidly packed around the pipe.

The inspectors made daily reports on printed blanks, recording the progress made and force employed, also the location of the Y-branches. These Y notes were recorded the following day on maps drawn to a scale of 1 in. to 100 ft.

Backfilling and Consolidating Ditches.

The backfilling, except the first covering of the pipe, was done by means of horse scrapers. After filling 3 or 4 ft. in this way the trench was flooded several feet deep with water from a fire hose and the material was dragged by the scrapers into the water. By this means the sand and gravel were so well deposited and settled, that when trenches were afterward excavated crossing those filled in this manner, the latter could hardly be distinguished from the undisturbed material adjoining, except in the lower part of the ditch, where the earth had not been consolidated by falling in the water.

The contractors at first paid the water company $1 per day for flushing trenches, the number not to exceed three at a time; this price was afterward doubled, but even then it was the most economical method for the contractor, and more satisfactory to the city than hand ramming would have been.

Testing.

After completion, all sewers (excepting the 24-in. and those where no water could be obtained) were tested by the contractor, in presence of an engineer or inspector, by flushing wooden balls through them by means of streams of water from hydrants.

Gates.

FIG. 6.—DETAILS OF GATES AT DISPOSAL AREA.

The balls used were of 2 ins. less diameter than the sewers for which they were intended, and were drilled to receive a cord. This cord was long enough to reach between manholes on main sewers and between lampholes and manholes on laterals. By working the ball back and forth, stones, gravel and even whole bricks were forced through the sewer to the next manhole below.

A wire screen of ¼-in. mesh was always placed in the lower manhole, in order to intercept all debris.

At the time of making the test all manholes, lampholes and flush tanks were examined to see that they were complete and in good order, and the flush tanks were filled and discharged. Notes were made of all defects found, and the inspector went around with the masons later to see that the repairs were properly made.

Many of the flush tanks were tested by filling them to nearly their discharging height, and then leaving them filled for several days. As the mains were tested before the lateral sewers were constructed, the testing of the latter brought more sand down into the mains, which were again cleared by flushing the balls through them.

Considerable use was made of small mirrors in examining the interior of the sewers, the sunlight being reflected by one on the street to another in a manhole, and the illumination was sufficient to show the joints for several hundred feet.

The 24-in. outfall sewer was cleaned by men passing through it, the inspectors following with lanterns. This important sewer was found in excellent condition, and showed the care taken in its construction by the contractor, Mr. John Marsden, of Utica, N. Y.

House Connections to Curb.

On July 20, 1895, the contract for laying 4-in. house connections from the sewer to the curb was executed, with Mr. John Siddall as contractor, and work was prosecuted whenever the weather would permit, until their completion, about May 1, 1896.

The work was let at an exceedingly low rate, viz., from 19 cts. per ft. for work in streets with car tracks and telford-macadam pavement, to 14 cts. in unpaved streets. The contractor has, however, put in many private connections from the curb to the buildings for about 30 cts per ft., and so has been compensated, partly, at least, for his low price on the city work.

Before commencing this work on any street, the owners were interviewed again as to their choice of location for the connection at the curb line. The connections to the curb are laid on a grade of 1 in 48; between the curb and the house much steeper grades are often used, though some of the residences are so far back from the street, with fixtures in deep cellars, that only the flattest allowable grades can be used.

The inspector examined the work, recorded the length of the connection, the number of the house, and the distance from the end of the connection at the curb to the line of one side of the building produced. Where there was a curbstone, a V was cut on it over the end of the pipe; in other places a stake was driven.

Ventilation.

The plumbing ordinance of the board of health requires that every plumbing system must be provided with a ventilating pipe extending above the roof, clear, and 4 ins. in diameter. In some cases this is secured by a separate 4-in. pipe carried above the roof from the sewer side of the trap on the main drain, but in most cases the trap is omitted, and the ventilation is secured through the soil pipe.

A Gas Explosion.

On Thanksgiving day, 1895, an explosion of illuminating gas occurred, which did considerable damage to the sewers and appurtenances. A 4-in.

gas main in Richmond St. was broken by some unknown means, and the break was not discovered for several days. The gas found its way to the manholes through the open joints of the 6-in. underdrains, and thence spread through the sewers in that vicinity. It was lighted by a property-owner on La Grande Av., who had a house connection pipe laid into his cellar, but not connected to the plumbing system. Smelling gas in the house, and being of an inquiring turn of mind, he investigated the matter with a light, and a number of explosions occurred in rapid succession, as manhole and lamphole covers were blown high in air, the effect reaching a distance of three-quarters of a mile.

Upon examination, some of the manholes were found cracked, and one of the lampholes was shattered. An examination of the sewers with mirrors and a test with balls failed to show any further damage, but by digging down to the sewer two other injured portions were discovered, one of about 60 ft. in the 12-in. sewer in Richmond St., and the other of 164 ft. in Putnam Ave., near Richmond St. The pipes were found cracked longitudinally, but none of the pieces was displaced.

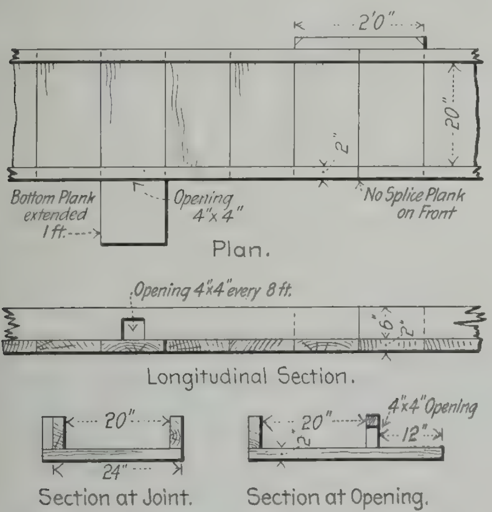

Fig. 7.—Details of Wooden Sewage Carrier.

Disposal Beds.

The outfall sewer reaches the beds, shown by Fig. 1, at an elevation of 63½ ft. above mean sea level, and the grades of the upper beds vary from 61.8 to 60.0, the latter being the ones most distant from the sewer. The elevation of the lower tiers of beds is about 5 ft. less.

The land purchased for the disposal beds comprises three farms of about 17 acres each, bounded at one end by Front St., the main thoroughfare from Plainfield to Dunellen and Bound Brook, and at the other end by Green Brook, the city and county line. The property is intersected by Dunellen Ave., parallel with Front St. and Green Brook, and by Rock Ave. transversely, both public roads.

At present only the two tracts nearest the brook are being graded for beds; the remainder, containing two roomy and substantial houses, is being farmed.

To bring the upper beds to the required grade for delivering the sewage on them by gravity, necessitated the excavation of nearly 60,000 cu. yds. of sand, the deepest cut being 10 ft. About 26,000 cu. yds. were excavated from the beds east of Rock Ave., and the material so excavated was deposited in the lower beds, the grade of which was made as low as the flood level of the brook would warrant.

TABLE II.—Details of the Several Contracts for the Plainfield Sewerage System.

Contractor.	Contract executed.	Work finished.	Character of work.	Total amount.
W. W. Cook & Co., Jamestown, N. Y.	Sept. 14, 1894.	June 1, 1895.	Mostly mains.	$19,608
M. Honan & Sons, Chester, Pa.	April 5, 1895.	Nov. 22, 1895.	Mostly laterals.	43,190
John Marsden, Utica, N. Y.	July 10, 1895.	Nov. 15, 1895.	Outfall sewer.	13,653
John Siddall, Trenton, N. J.	July 20, 1895.	May 15, 1896.	House connect'ns.	5,529
Washburn & Washburn, New York	Oct. 10, 1895.	July 1, 1896.	Disposal beds.	31,212

Mr. Allen Hazen, of Boston, who had been engaged by the common council to report on the availability of the materials in the disposal bed area for the purpose intended, advised that the different grades of sand should be kept separate in filling, the experiments at Lawrence having indicated the danger of placing layers of coarse sand over fine, an impervious layer being formed at the junction. For a similar reason the surface of the beds, when above sub-grade, was ploughed and kept loosened as the fill was made over it.

The top soil, to a depth of at least 1 ft., following the slope down to sub-grade, was removed and placed in the embankments.

In excavating the top-soil, and wherever the haul was short, slip and wheeled scrapers were used, but in the deeper cuts the excavation was made by a steam shovel. West of Rock Ave., a continuous line of carts moved the sand from the shovel to the lower beds; east of Rock Ave., dump cars and a light construction track were used to good advantage.

Underdrains were laid under each bed, 39.2 ft. apart, and from 5 to 7 ft. deep, the grade being 1 in 300.

In the upper beds 3-in. agricultural tile was used, emptying into manholes constructed of 24-in. vitrified pipe. From these manholes, 4-in. tiles continue under the lower beds to the brook, terminating in 12-ft. lengths of cast-iron water pipe.

Extra Work—Fixed Prices.

Extra concrete, per cu. yd.	$5.00
Rock excavation, per cu. yd.	3.00
Sheeting or shoring ordered left in place, M. ft.	20.00
Gravel foundation, per cu. yd.	.75

Disposal Beds—Washburn & Washburn, Contractors.

Excavation, low lands to sub-grade, per cu. yd.	$0.125
Excavation—General, per cu. yd.	.17
Overhaul, per cu. yd.	.06
Screening tank, cost, complete	977.76
Gate chambers, 4 × 6 ft.	60.00
" " 4 × 4 ft	50.00
18-in. gates—extra, each	15.00
12-in. gates—extra, each	6.00
18-in. sewer in embankment, per ft.	.66
12-in. pipe outlets from gate-chambers, per ft.	.55
3-in. tile underdrains, per ft.	.15
4-in. tile underdrains, per ft.	.10

Note.—Excavation for 4-in. drains was about 18 ins.; for 3-in. drains, about 6 ft.; manholes (of 24-in. pipe—over underdrains), $20 each; wood distributing channels, tarring extra, 28 cts. per lin. ft.

For a distance of 25 ft. above the manholes, the drains are composed of 4-in. vitrified pipe, laid with cemented joints, to prevent the water from the upper beds from leaching through to the lower.

The drop from one level of the underdrains to the other is made in the manholes; these manholes prove convenient for obtaining samples of the effluent as well as for examining the drains. In bed No. 11, where the material was extremely fine, an extra drain was laid between each of the others. While the underdrain ditches were being excavated, samples of the materials were taken at frequent intervals and kept in numbered bottles; the notes thus obtained were transferred to the profiles of the drains, making an accurate record of the original materials in each bed, which range from coarse to very fine.

The excavated sand which has been filled into the lower beds runs much more even in size than the test pits indicated, so that, while the specifications classified the materials as "fine," "medium" and "coarse" sand, only one bed, No. 12, has been entirely filled with coarse sand, * and one bed, No. 11, naturally fine, has been leveled up with fine sand. The remaining sand is quite uniformly "medium," and the operation of excavating by the steam shovel, emptying into carts and dumping into the fill, served to thoroughly mix any thin layers of fine sand encountered. The medium sand is about 0.20 to 0.25 mm. (0.008 to 0.01 ins.) effective size.

The ordinary dividing embankments between the beds are 2 ft. high and 2 ft. wide on top, with slopes of 1½ to 1; the embankments containing the carrier pipes are 4 ft. wide on top and about 4½ ft. high; those serving as roadways are made 10 ft. wide on top.

Enough of these roadways are provided to give access to all the beds. Along the brook the roadway embankment becomes a levee, which was mainly formed from the stiff clay found in excavating the beds along the brook to sub-grade. The amount of excavation required to bring the lower beds to sub-grade was 5,875 cu. yds.

Contract Prices.

The contract prices for the various parts of the work are given in Table I., and some facts regarding the several contracts in Table II.

Screen Chambers.

The 24-in. outfall sewer terminates, with a curve of 79 ft. radius, in the screen chambers shown on the plan, Fig. 1, and by the view and the details, Figs. 3 and 4, respectively. The sewage is admitted from the influent chamber to either of the two 5 × 8-ft. screen chambers through the 18-in. gates. At first, when the quantity of sewage was very small, both these gates were kept closed until the sewage filled the 24-in. pipe, when the 28,000 gallons thus stored up were run out upon the beds. At present the sewage is allowed to flow continuously through one or the other of the screen chambers, where the sewage rises through the screens, and flows out through the 24-in. gates to the main carrier pipes. The screens are constructed of ⅝-in. galvanized wrought-iron bars, spaced 1 in. apart in the clear, are submerged 0.3 ft., when in use, and can be removed if required.

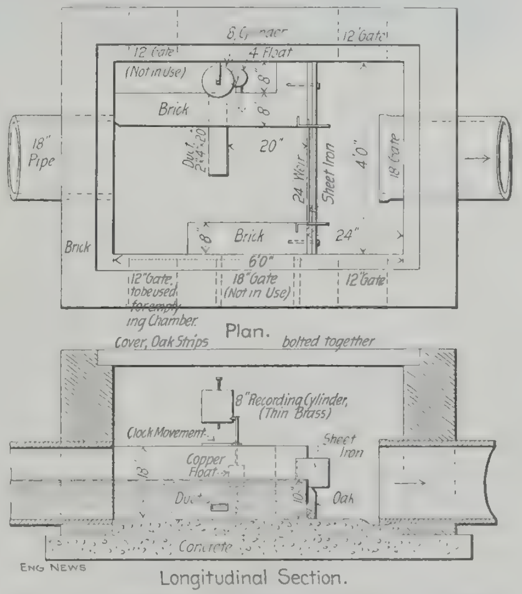

Fig. 10.—Apparatus for Gaging the Flow of Sewage

The entire interior of the screen tank is lined with imported, white enamelled brick, coped with bluestone. The tank is covered by a frame building.

---

*Effective size about 0.30 mm. (0.012-in.)

The two chambers are intended to be used alternately, to allow of cleaning one while the other is in operation. The screen chambers are each provided with an 8-in. cast-iron drainage pipe with gate valve, the two pipes converging to a cast iron Y-branch, and then continuing, by an 8-in. vitrified pipe, to the screenings beds on the low land.

The two screenings beds, or sludge beds, are each 75 ft. square, and are located on the swampy land east of Rock Ave.

Sand was excavated from the adjacent hill, and filled to a depth of about 4 ft., to form the beds. Four-inch tile underdrains are laid under the beds, emptying into ditches leading to the brook. These drains are intended to form part of the system of underdrains for the beds east of Rock Ave., when they are needed. The screenings beds may be moved nearer the brook when the area now occupied is needed for filtration beds.

About every three days the screenings are flushed out of the chambers onto these beds, and after the material is sufficiently dry, it is raked up and carted to the farm for fertilizer; this amounts to two or three cart loads each week.

The main carrier pipe is 24 ins. in diameter to the first gate chamber, where it is reduced to 18 ins.; an 18-in. gate is provided at this point for use when the easterly farm tract is graded for beds. The carrier is continued 18 ins. in diameter throughout the work at present completed. The pipes to be laid in the lower beds will be reduced to 15 and 12 ins.

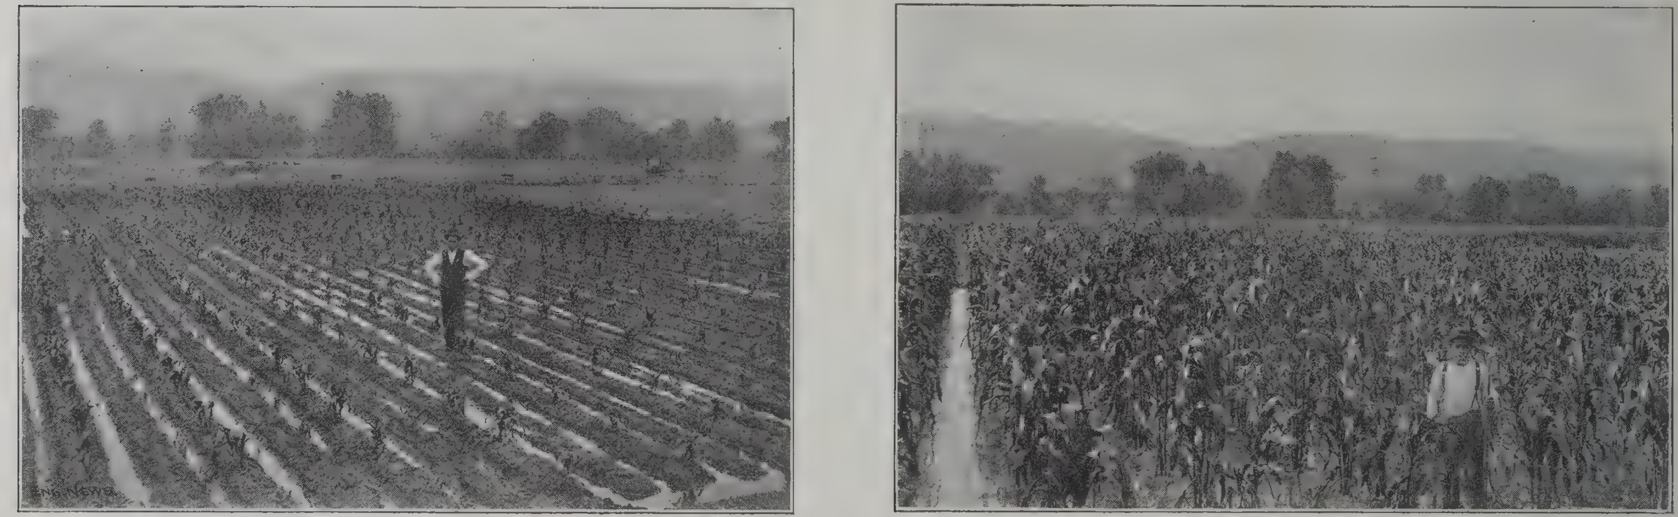

FIG. 8.—IRRIGATING IN JUNE.

FIG. 9.—CORN IN JULY.

FIGS. 8 AND 9.—VIEWS SHOWING CORN GROWING ON BED NO. 8.

Gate chambers are constructed on the main carriers at each embankment, as shown by Fig. 5, the ordinary ones being 4 × 4 ft., and containing one 18-in. gate and from two to four 12-in. gates. At junction points of the main carriers, the gate chambers are 4 × 6 ft., and contain an extra 18-in. gate. The details of the gates are shown by Fig. 6. The guides for sustaining the 18-in. gates are not placed over them, as shown for the 12-in. gates, but in the adjacent side walls, in order to allow more room for opening the gates.

From the gate chambers wooden distributing channels will extend along two sides of each bed, and a few are now in position.

They are constructed, as shown by Fig. 1, of 2-in. spruce planks, are 20 ins. wide in the clear, the sides 6 ins. high (except the section nearest the gate chamber, which is 12 ins. deep) and the bottom planks are 24 ins. long, spiked to the side pieces.

Openings 4 × 4 ins. are provided every 8 ft., and at each opening the bottom plank is extended 12 ins. to spread the flow. Before being used, the channels are covered, inside and out, with coal tar, applied hot.

These tarred distributing channels do not retain accumulations of any kind and give entire satisfaction.

Messrs. Washburn & Washburn, the contractors for constructing the disposal beds, had a large and complete plant and a very efficient force. All their work was done in the most conscientious and satisfactory manner.

Operation.

On December 31, 1895, permission was given to make connections with the sewers, the immediate cause for action at that time being an injunction by the Supreme Court restraining the residents of North Ave. from draining into a storm sewer which emptied into Green Brook. It was supposed that not many others would connect, but 88 applications were received in January, and by the end of April about 450 permits had been granted. All this was before a single bed had been completed, and when but four could be used at all. Up to July 1, 1896, 550 permits had been issued. Eight beds, Nos. 1 to 8, are now planted with corn, in rows 4½ ft. apart. These beds are irrigated about every three days, and the corn is in fine condition, promising a good crop. Two views of Bed No. 8, taken one in June and the other in July, are shown by Figs. 8 and 9.

The beds were planted at different times, as fast as they were finished by the contractors, so the corn varies from that which is "tasseling out" to that only a few inches high. Of course, the corn has no nourishment except the sewage, as the beds were clean sand before use.

The remaining beds, Nos. 10, 11, 12, 14, 15, 16 and 20 are used as filtration beds, being flowed whenever the sewage is not needed on the corn beds.

There is more scum left on the beds than is found in places where the sand is coarser (as at So. Framingham and Marlborough, Mass.), but this dries up without any offense, unless the ground settles, and the sewage "ponds," when considerable odor is caused before the thick deposit dries up. To obviate this trouble the beds are leveled up occasionally by means of a road scraper and rakes, and the aim is to keep the surface as even as possible.

There was a great deal of opposition expressed by the neighboring owners, when the proposal was made to locate the beds so near their property and dwellings, and every odor has been noted and complained of by these men, who make almost daily inspections.

It is probable, however, that the principal objection to the beds is the name of having them located in the vicinity of the property in question, as the odor rarely reaches beyond the beds, and is seldom offensive there.

The completed system includes 23.65 miles of sewers (not including pipes at disposal beds); also over six miles of house connections to the curbs; all of the best materials, and constructed in the most careful manner. These have cost, with all appurtenances and expenses, and with fifty acres of good land, and two good residences about $160,000.

The weir and recording device shown by Fig. 10 has recently been placed in one of the 4 × 6 ft. gate chambers. The apparatus is similar to that at Brockton, Mass.

The float is of copper, 4 ins. in diameter, and weighted with lead. The recording cylinder is made of thin brass, and revolves once in 24 hours. The pen is a V-shaped trough attached to the float spindle by a light steel spring. Dr. Draper's thermograph ink is used. The head on the weir is read occasionally by means of the hook gage to check the diagram.

The flow at present is about 11,000 to 13,000 gallons per hour from 11 a. m. to 7 p. m., diminishing to 5,000 about 4 a. m., and beginning to increase again about 7 a. m. The total for 24 hours is about 230,000 gallons.

It is said that the Pond Machine Tool Co. furnishes between 50,000 and 100,000 gallons of water per day. The remainder would amount to about 55 gallons per head, allowing five persons to each building connected with the sewers.

THE ARTISTIC ELEMENT IN ENGINEERING.*

That the artistic element is not recognized as it might or ought to be in the present American day is natural. The rapid development and growth of our land, the intensive study of science and the concentration of the effort put forth to adapt it to every-day affairs, have exalted one phase of the economic idea, the quick attainment of profitable results, and clouded the truer, broader meaning that looks toward the best things and the highest life of the people. Into the midst of this active, restless, business life entered the engineer, doing more and more of its work and becoming more and more a recognized part of it and an undisputed element in its growth. He has acquired the characteristics of the life about him—zeal, energy, alertness, readiness in meeting quickly changing conditions, and absorption in the work in hand. He plans rapidly, and executes to-day with an eye for to-morrow's profits.

With an engineering practice based solely on immediate results by way of expected profits in dollars and cents the esthetic element has little to do, though even here its absence may mean financial loss. But from the standpoint of this paper, engineering is to be considered in the broader light of Telford's well-known definition, "The art of directing the great sources of power in nature for the use and convenience of man," while the engineer is he who designs and executes engineering works. With an engineering practice based on a generous interpretation of the above, the artistic has much to do.

The engineer is primarily a designer. He works with the materials of Nature as his medium and her powers as his tools wherewith to express his thought and his purpose to serve and benefit man. Just as in the making of a picture the brushes, paint, and canvas are not the chief things, so here it is not the wood, steel and brass, or the powers of gravity, steam, air, and electricity, that are most important, but rather the character and quality of the design and the degree of realization in its execution. The design may be bad or good, according as it ignores or harmonizes with principles underlying all such acts of creation. The result may be a happy one only when the means employed are rightly chosen and properly adapted to the end sought. In this process of creating something of value, something that helps man to a fuller, richer and better life, the artistic cannot be left out. In its absence the design falls far short of its possible perfection, and man is deprived of what is due him, though not perhaps distinctly conscious of the loss. In a certain sense, then, every engineer is an artist, and in some directions at least, as in architecture and other forms of construction and in the making of public parks, the result of his cultured brain may attain to the dignity of a work of "fine art."

---

*An address delivered by Frank O. Marvin before Section D of the American Association for the Advancement of Science, at the meeting at Buffalo, N. Y., in August, 1896.

To the superficial or hasty thinker there may appear a conflict here between the utilitarian and the artistic, but there can be no real antagonism. The result of any act of designing is to be judged as a whole and in the light of all the purposes to be fulfilled. The physical conditions imposed by the materials used and the forces of nature employed are to be met. These conditions must be expressed in the design frankly and candidly, and in such a way as to indicate clearly its purpose, and to gratify the observer through its proportions, symmetry, harmony and decoration. The end desired must be attained in the most direct and simple way, so that the expenditure of money may be a minimum. These are the three elements of design. The scientific, the esthetic and the financial. A disregard of the first may mean structural or organic weakness on the one hand, or, on the other, an excess of material that unduly adds to the cost and at the same time may produce heaviness or ugly proportions in the completed work. Non-compliance with the demands of the second makes the design fail in fulfilling its complete mission, and this applies with the same force to those cases where a poorly directed attempt has been made to be artistic in expression, as to those in which no attention whatever has been paid to the matter. Artistic treatment often costs money, yet the mere expenditure of cash will not secure it. On the other hand, the proper display of good taste may often come without the spending of a dollar more than is made necessary by the other conditions surrounding the problem.

The current engineering practice gives great attention to the first and last of these elements, and but little comparatively to the second. There is no branch of it but would be benefited by adding to scientific and business ability a knowledge of the principles of artistic design, and an impulse to give an expression to it. The effect on the life of our communities and the nation by such a change is not easily estimated.

Some recent installations of power plants illustrate a movement that will have considerable influence on engine design. In many of our larger cities there are engine-rooms fitted up in elegance, with marble floors and wainscot, decorated walls and ceilings, brilliantly lighted and with all the appliances of the plant, engines, dynamos, switchboards, and even the smaller accessories in keeping with the surroundings. These plants are used as drawing cards or advertisements. There are other plants, not so used, where there is displayed less elegance, but fully as much artistic sense in adapting the room and its treatment to its purposes. In many of these places only the enclosed type of engine can be employed. In all of them the standard of maintenance must have its influence on the matter of design, which will in turn react on the former. An engine might pound itself to death in a dark basement, but would have its slightest vagary looked after in one of these better planned housings. This result cannot be entirely accounted for by the larger room, the better light, the rules and regulations. There is a refining, educating influence in these artistically planned constructions that makes better men and more efficient workmen of the attendants. Whatever they may cost, there is a credit side to the balance sheet.

Our railways are contributing toward this change. They have found the decoration of passenger trains a profitable thing, and, so stimulated, have carried it to excess. More significant still is the tendency to adopt high standard of maintenance, under which the roadbed is kept trim and neat, flanked by sodded slopes, and bordered by clean and well-kept buildings, and which also requires the rolling stock, the shops, and the yards to be maintained in a high state of efficiency. This is not necessarily in itself artistic, but it furnishes at least a necessary foundation. That the railway management understands to some degree the commercial value of the artistic element in its business is further evidenced by the nature of its advertising, that seizes on any advantage of scenery or artificial effect that is at hand.

Not much can be said in praise of the artistic qualities of our bridges, for these attributes are conspicuous through their absence. The American bridge satisfies the conditions of stability and least cost, but of beauty of line or balanced proportion that makes it fit into and harmonize with the landscape, or even that makes it considered by itself attractive, it has little. And this is to be the more regretted, because an intelligent application of right principles would improve the effect, without adding much, if any, to the cost, or making the structure less safe and durable. It is true that the truss with parallel chords, especially of the through type, does not lend itself readily to artistic treatment, yet even here something can be done. It is not so much of adding ornament as the proper treatment of the organic lines, the length of spans, the relation of length of panel to height of truss, the location of the piers, and the form of their outlines. Ornamentation is not to be used so much for its own sake, but rather where it is needed to accentuate these organic markings. There are some truss bridges of such size that they give pleasure to the observer through their massiveness, though lacking in other desirable qualities. The cantilever, like the Pratt and its relatives, is difficult of treatment, while arch forms, either braced or of the suspension type, are naturally pleasing and best adapted for artistic expression. Of these types we have a few satisfactory examples, like the Eads and the Grand Avenue Bridges at St. Louis, and the Brooklyn and Washington Bridges at New York. In our public parks are to be found many small bridges of good design, while in our cities there are some creditable ones of larger dimensions. There is some tendency toward the use of curved chords in bridges designed for urban use, and a further evidence of interest in the curved line through the introduction of the Melan arch. In some respects it is unfortunate that the economical element has driven out the stone arch, which possesses so many of the features of a beautiful structure for most situations, and it may be that this new form will become a substitute for the old, with added characteristics of its own. However much we may admire the inventive genius and mechanical ingenuity of those who have worked out the types of rolling or lift bridges that cross the Chicago River, the less said about the beauty of the designs the better. Perhaps the environment imposes ugliness on the designer. But that problem is hardly solved yet, and will not be until some man gets hold of it that combines aesthetic with scientific qualities, and has insight keen enough to see the possibilities of the situation and adroitness enough to manage, not only the physical, but also the human elements.

In the entire field of engineering there is no portion of it that includes a greater variety of intricate and difficult problems for solution than that connected with municipalities. Here the engineer has to do with matters touching the home life, the business life and the larger life of the city as a whole.

The engineer here comes in close contact with the people that daily and hourly use the results of his work. He already influences their health and bank accounts for the better, gives them greater ease and convenience at work or play, and saves their time. This is what is asked of him, and he meets the demand well. But what an uplift would come to city life, how much richer it would be, if he could put an artistic quality into his designing, and the people would learn to appreciate it! It is not to be inferred that there is an entire absence of this, but rather that artistic effects have been largely confined to individual cases, and not made manifest in the general life of the city.

For instance, there are numerous examples of suburban dwellings, beautiful internally and externally, and with harmonious settings; there are occasional business blocks whose treatment is satisfactory, but very few public buildings that have an adequate artistic meaning and are so situated as to express this advantageously if they did possess it. Without detracting in the least from the acknowledged merits of the design of Trinity Church, Boston, it must be admitted that its roomy location on one side of an open plaza adds greatly to its effectiveness. Think of its being placed in the middle of a block on Washington Street, or set in the midst of brown stone fronts on Fifth Avenue! All public buildings need both room and appropriate setting. They are the larger and more important pictures in the gallery of city structures; yet under the prevailing system of rectangular blocks, bounded by long, straight, and narrow streets, the hanging committee has nothing but the walls of corridors on which to place them. The worst of the matter is that the exhibition is a permanent one. Along these alleyways must also be hung the narrow, vertically elongated panels that seem to be so popular to-day, in favor because they pay. The observer needs a twenty-story ladder in order to study their details, or even to know if they have any, and can find no point from which they may be seen as entireties. At their sides hang strings of pictures whose horizontality exaggerates their skyward tendency. It is not the modern tall building in itself that is here objected to, but its location on sites that will not admit of a display of its best qualities. With wide, clear spaces about them and effective grouping they may be made agreeable, as is illustrated by the happy combination at the southeast corner of Central Park.

One of the good results of the tall building craze is the bringing closer together of two branches of designers; from the architect the engineer will learn more of art, and he will teach the former better construction. While retaining their separate functions, the collaboration will result in a higher mutual respect and appreciation, and a better grade of work on the part of each.

The rectangular plans of American cities are neither adapted to meet aesthetic conditions nor the demands of traffic. The long streets, without variation in width and direction, and without the breaks afforded by little parks, are tiresome to the eye. They are not placed with any regard for the topography or the natural features of the landscape, or to give prominence to some important structure, nor do they furnish directs lines of travel. But the plan is weighted down to the ground by millions of money. So it is not a question of what it ought to be, but one of mitigating the present evils and avoiding any repetition of these in the future.

Radical treatment must be resorted to by way of diagonal avenues from congested centers, and the widening out of the intersections of important streets into parks and plazas. There must likewise be an heroic struggle with the water fronts and internal water-courses, places full of picturesque possibilities, though usually given over to filth and ugliness. These changes are made imperative not only by esthetic requirements, but also by the demands of health and business.

In the planning of additions to large cities, the designer is hampered by the supposed necessity of tying to the older plan, by the desire of owners and speculators to realize to the largest extent on the sale of lots, or by his uncertainty as to what the future growth and character of the population may be. An examination of the block plan of many of our cities would show a heterogeneous arrangements of streets, especially in outlying districts, without regard to mutual relations, matters of grade and drainage, or artistic position. This irregularity may be more inconvenient and less pleasing than a right-angled plan. Our towns and smaller cities reproduce in miniature the conditions of the larger centers. Here, again, it is a question of improvement, instead of original design, only the problems involved are not so intricate and their solution not so costly. So it is hardly possible for a designer to plan an ideal city, or to have the full swing and liberty of the men who laid out the city of Washington and established its system of grades and drainage. But in spite of difficulties there exist some suburban districts laid out, built up, and adorned on the principles of good taste. Thanks to the systems of rapid transit that are increasing the number of these attractive places!

In the design and maintenance of water supply plants, American practice shows some respect for the artistic element. This is not confined to any particular system or any part of any one plant, but is quite general. The engine houses are not ugly and their interiors are often attractive. Gate-houses, aqueducts, and dams are decoratively treated, and form pleasing features in the landscape. The slopes of reservoirs are kept trim, and the grounds generally turned into lawns with flower beds, and perhaps a fountain. No doubt the sanitary conditions imposed have had much to do with this, but the result is none the less in good taste. We cannot avoid, however, a stray shot at the ugly stand-pipe, with conical cap, sometimes seen in our smaller towns. This is unnecessary. When enclosed it has been made an interesting object, and even the bare pipe can be ornamented in such a way as to relieve its nakedness.

There is much encouragement in the growing appreciation and enjoyment of public parks and boulevards. Cities and towns all over the land are trying to beautify what they already have, and are adding new territory to their park resources. Admirable skill has been shown in utilizing the natural features of the local landscape, the rocks, tree masses, meadows, ravines, ponds and streams, the wide expanse of ocean or glimpses of bright water. The curving roads and paths, with undulating gradients, have a beauty of their own, and lead one from point to point of the ever-changing scene, and yet bind it all into one harmonious whole. While the landscape engineer deserves credit, not so much praise can be given park commissioners for the artificial adornments which they have added to his work. Notwithstanding the fact that these are sometimes labelled as artistic, they do not always fit in appropriately.

The writer firmly believes that there is a latent aesthetic quality in American life that is now struggling to find means for its gratification and methods of expression. Before there can be knowledge of its meaning and power there must be many attempts and many failures. The whole process is one of education, and that largely in the school of experience. This applies to the industrial and constructive arts, as well as to the fine arts. The engineer will share in the general movement, but this is not enough. As a designer of so much that the world needs for daily use he must do more than keep up, he must keep in advance. He must not only have a capacity to enjoy, but also the power to originate and apply. To this end he must give preliminary study and thought to the principles of aesthetic design, so gaining an intellectual knowledge of them. American engineering schools are doing little or nothing to help the young engineer to this. So far as the writer knows, there is but one American textbook, Professor Johnson's book on bridges, that includes any discussion of the matter. A course of study in engineering esthetics near the close of college life would be a great help.

THE MOVING OF A FRAME BUILDING for a distance of 128 ft. was accomplished at Locust Point, Baltimore, Md., on Sept. 1. The building was a two-story frame warehouse of the Baltimore & Ohio R. R., containing a stock of crockery and glassware, and said to weigh 1,500 tons. The work was done by the aid of 1,000 iron pipe rollers and 90 screw jacks.

London Agencies: Kegan Paul, Trench, Truebner & Co. (Limited), Paternoster House, Charing Cross Road; Sampson Low, Marston & Co., (Limited), St. Dunstan's House, Fetter Lane.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; *6 months,* $2.50; *2 months,* $1.00; *Single copies,* 15 *cents. To all other countries in the Postal Union, add* $2.08 *per annum* (4 *cents per number*) *to above prices for postage. No club rates allowed. Mailing addresses may be changed at will by sending both old and new address. We shall be obliged if subscribers who fail to receive their papers promptly will notify us without delay. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number* 326 *means that subscription is paid to the* 32*d week* (*that is the issue of Aug* 6) *of the year* 1896; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: 20 *cents per line agate measure. Want notices, special rates, see page* 22. *Rates for standing advertisements sent on request. Changes to standing advertisements must be in hand on Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

The steam turbine is a promising machine which has as yet been but little applied to practical work, and there is therefore special interest attached to the results of the first important test that has been made in this country of a large de Laval steam turbine, which will be found in another column of this issue. The result obtained, 19,275 lbs. of water per electrical horse power hour, equivalent to 17,348 lbs. per brake horse power hour, is so low as to command respectful attention from all those who are considering the installation of new engines for furnishing electric power. The record of steam consumption at variable loads is quite remarkable, only 20.22 lbs. of water per electrical horse-power hour being used at 56 per cent. of full load. Not only in steam consumption does the steam turbine threaten the position of all but the highest type of reciprocating steam engines, but in the simplicity of its mechanism, the smallness of space occupied, and the little attention it requires while running. When a total equipment delivering 266 HP., including the steam turbine, gearing and two dynamos, requires a space of only 13 ft. 3 ins. × 6 ft. 5 ins × 4 ft. 3 ins., the saving of space, as compared with ordinary engines, is a most important matter in cities where space is expensive.

◆

Without attempting to enter into the theoretical and political situation, some extracts from the 1895 annual on "The Mineral Industry," of the United States would seem to be pertinent, simply as information. Our readers can draw their own deductions. According to this carefully compiled volume of statistics, the value of the total mineral production of the United States, for 1895, was $678,000,734, including in the list 74 separate items. On the basis of a standard of market value at the place of production, coal holds relatively the first place with 31.8 per cent., or nearly one-third of the total value, and pig-iron comes next with 16 per cent.; the two together making nearly one-half of the whole value. There is a very wide gap between the value of these products and the third, which is gold, with 6.9 per cent. But the value of the silver product only amounts to 4.5 per cent. of the total, and is exceeded in value by the production of building stone throughout the country, and it is very little greater than the value of the lime burned last year.

A lately published open letter to Congressman Wilson, in connection with his bill "to organize and increase the efficiency of the personnel of the navy," makes one of the best presentations of the case of the engineer corps, and of the necessity for some speedy and radical measure of relief that has yet been made public. Congress is out of session just now, and things political are much mixed; but as the subject is to be vigorously pushed in the next Congress, and as educational methods are much in vogue at the present time throughout the country, we cannot refrain from some comments on this letter. The writer is Mr. Asa M. Mattice, late of the Engineer Corps, U. S. N., now a consulting engineer with Mr. E. D. Leavitt, and at one time an assistant to Commodore Geo. W. Melville, Chief of the Bureau of Steam Engineering, and highly commended by that department chief as an officer of exceptional qualifications and merit. While the letter of this ex-officer is exceedingly sharp and directly charges all of the existing trouble and contention to the actions of certain line officers who aim to control all legislation relating to the personnel of the navy, the actual conditions stated by Mr. Mattice tell a story of their own that ought to have a marked effect upon those to whom alone the engineers can look for relief. The Naval Register for 1896 gives a list of 714 line officers to 173 engineers; a ratio of 4.13 line officers to each engineer. In 1864, under war conditions, there were 2,846 regular and volunteer officers of the line to 1,728 engineers of the same branches of the service, or a ratio of 1.64 to 1; and in 1866, the regular line officers numbered 395 to 379 regular engineers, or practically equal number in both corps. The significance of this contrast between past and present conditions will be better understood when it is realized that the most powerful steam warship of 1864, the "Minnesota," had engines of 1,000-HP., while the protected cruiser "Columbia," of our new navy, has 18,500 I. HP., 90 engines and 172 steam cylinders, with the mass of varied and complicated machinery this power equipment would imply. Yet the "Minnesota" had nine engineer officers in 1864, and the "Columbia" has only four officers responsible for its vastly more powerful and important engines.

◆

The original line officer was a sailor, and upon his training, skill and general knowledge depended the efficiency of his ship as a war-machine and its safety at all times, either on a lee-shore or in the face of an enemy. He was directly responsible for the motive power of the vessel and the handling of men and sails. To-day the line officer may direct the movements of his ship as before; but it is steam engines and not sails that do the work; and it is the engineer and not the line officer who is really responsible for the conditions of the machinery upon which the whole efficiency of the ship now depends. We fight as well as move by steam; and in the last thirty years the whole warship has practically been converted into one vast engine-room with an intricate maze of machinery that may make the difference between victory and defeat by failure in any one part of it.

◆

How in the face of this radical and most important change in fighting and maneuvring conditions any loyal servant of the government can advocate an increase in the number of line officers at the expense of a corresponding decrease in the engineering staff is one of those problems that no man outside of the U. S. Navy can find out. With triple and quadruple engines, twin and triple screws, power for handling battery and ammunition, electric lighting and the multitude of mechanical devices found upon a modern battleship or cruiser, it is engineers we want and must have; and it may happen that the near future of naval warfare will demand that all naval officers be engineers before anything else. But at present each corps has its special and important duties to perform and the engineering staff very properly does not ask for command outside of its own distinct engineering department. This it should have along with the official status that the grave importance of its duties demands. The "warrant officer" scheme proposed by interested line officers is the veriest nonsense, that reflects little credit upon their good sense and would, in an emergency, very possibly react upon themselves and the government in causing the loss of a valuable ship. The demand in the engine-room, even more than upon deck, is for brave, highly educated, skilfully trained officers, with a rank that will ensure respect and obedience from every subordinate; and this can never be secured under any warrant system. Upon the engineer depends the efficiency and safety of government property, amounting to millions of dollars in value, the lives of officers and men and the honor of a nation; and to attempt to reduce this officer to the grade of a gunner or ship's carpenter is to put a premium upon disaster, even though there should be "one engineer" in a divided engineering command on each ship. If, as Mr. Mattice charges, the opposition to much needed reform in the personnel of the whole navy comes from a few bigoted line officers who have assumed control of naval affairs, the sooner Congress sits down very hard upon this fossilized clique the better for the credit and condition of our rapidly growing navy. Time will doubtless compel the reform; but the government cannot afford to await a contingency that may couple with it national disaster, and possibly discredit. Congress has the power to abolish this ring, if it does exist; and the apathy of Congress must be held responsible for any loss that may be sustained as a result of a continuation of not only an unjust but a very unwise treatment of a most worthy and necessary corps of government officers.

THE ARTISTIC ELEMENT IN ENGINEERING.

It is gratifying to note that the artistic possibilities of some branches of engineering are receiving much more attention of late than ever before, although still sorely neglected in most quarters. Some of the attempts to combine the artistic with the utilitarian have been abortive, as might have been expected from persons not possessed of even an elementary knowledge of the principles of art, while others are so creditable as to show conclusively that art and engineering are not incongruous, and to promise even better things for the future.

To those interested in the artistic side of engineering, and we trust all our readers are, we commend the abstract, published in another column, of a paper on "The Artistic Element in Engineering," by Mr. Frank O. Marvin, read before the Association for the Advancement of Science.

The author treats his subject in an interesting and sensible manner, indicating clearly why the matter should be given serious consideration from both the esthetic and financial point of view, and citing many phases of engineering into which the art element should enter.

The points so well made in the paper raise the extremely practical question, How is this artistic element to be introduced? For obviously it is still chiefly conspicuous by its absence in most American engineering works. Evidently the man who has been designing engineering works without a thought as to their artistic features until to-day cannot resolve to-night to introduce the artistic element hereafter and put his resolve into execution to-morrow. Much time and patient study will be required before the principles of art can be grasped by the novice and embodied in his work, but let us hope that in reality there are few engineers so devoid of art knowledge that some improvement in their work may not be expected from the moment their attention is directed to this end and thought and effort given to it.

The engineer has his limitations in this matter. He is not called on to take up the work of either the architect or the landscape engineer, any more that these two are expected to trespass on the domain of the sculptor, or the architect proper on that of the painter. But just as the work of the architect overlaps that of both the sculptor and painter, so does the work of the engineer overlap that of the architect and landscape engineer at some points. This makes it necessary for all to work in harmony, each realizing his own limitations and the possibilities of the other, and not hesitating to call for help when better results can be obtained by co-operation than by individual effort. Such co-operation already exists to a gratifying extent, but there might with advantage be much more of it and it should oftener begin early in the design of the work in hand, instead of waiting until some of its features are fixed which might have just as safely and cheaply been so modified as to lend themselves more kindly to artistic treatment.

But however fully the engineer may work in harmony with the architect, he must himself have some artistic feeling and be able to express it in the broad outlines and even in some of the minute details of his designs, for it will not always be practicable for him to call on an architect, and he should in any event have a sufficient understanding of art to make possible a bond of sympathy between them. The engineer will find it to his credit if he is able to so group and proportion his materials as to get the best effects in grand massiveness and stability, or airy lightness without a suggestion of frailness and perishability. He must realize that ugly details mar structures, no matter how pleasing their general outlines and proportions may be, and he must know what ugly details are, so that in case he is not able to design anything else he may call upon some one who is. He must have an innate sense of the fitness of things, placing ornament only where it belongs, and always using it in a proper degree of richness, such as the character of the work in hand and the material and money at his command will warrant. His means will oftener than not be limited, especially for ornamental purposes, so he must know the artistic capabilities of his materials and be able to make much out of little.

No five words can be more helpful to either engineer or architect than the maxim, "ornament construction, never construct ornamentation." This means simply to make each useful and essential part of a structure as artistic as may be consistent with its object and to stop there in attempts at ornamentation, instead of "sticking on" ornament. For example, a bridge railing would as fully prevent passers from falling into a river or ravine if it consisted of only a flat piece of iron supported by plain iron bars at considerable intervals, but something more pretentious, if not always more artistic, is attempted, and in this one simple detail the engineer too often fails by selecting a design that would look well enough if used to fence in a front yard and was well veiled by shrubbery, but is utterly unsuited to its actual massive and simple surroundings. As an example of what to avoid, there might be mentioned one costly bridge in the city of Philadelphia which is so disguised by galvanized iron applied to the panels that it presents a long arcade of masonry arches of short span supported upon space. The details are carefully carried out in this case, but the original conception is wrong and the general effect is very unpleasing—simply because it tells a structural lie in attempting to conceal the true lines of stress.

If what has preceded is true, it may well be asked, how is such artistic perception and skill as may be necessary or desirable to be obtained by the engineer? As already urged, it is not a mere matter of resolution, although that is the first step. Engineers already in practice will find ways of improving themselves, if once they set about it, making use of the same general methods they would pursue to acquire knowledge in some other lines. They will naturally have recourse to books on art, to lectures on the subject, when possible, and, above all, to a close study of such examples of art in engineering as are available for the purpose. But with the many pressing demands which an engineer in good practice has to meet, any great progress is not to be expected for some years, at least, beyond an appreciation of the artistic element and a realization that, except in minor matters, he must call upon some one with more artistic training and ability than he possesses.

With those looking forward to engineering as a profession the case is quite different. They may pursue the study of art to such an extent as they see fit, provided the advantages of such a course are impressed upon them, and facilities for it are available without such great trouble or expense as to make it impracticable for the majority of engineering students. As a matter of fact, such students are really dependent on their instructors for guidance in this matter, and in many, if not most, cases for even an intimation that such knowledge is desirable, to say nothing of being necessary, for the highest degree of success in most branches of engineering.

There is practically no opportunity for such training in our engineering schools, so that the student must seek it elsewhere or go without it. We will not venture to suggest how the matter should be approached by the engineering schools, nor even to say that they should attempt to provide such training. But we do not hesitate to urge that if art in engineering is to become general the engineer should have some instruction in it, and that this could be obtained most naturally and certainly during his schooldays.

Our engineering courses are already overcrowded with subjects which pertain to the general education and development of the man, rather than the fitting of the man for his chosen calling. In some of these schools the youth is taught, and imperfectly at that, to write English, is given a little history, a smattering of botany, and takes up many other studies which he might very properly have completed before beginning his engineering course.

If these general subjects were studied before entering the engineering school, or, in other words, if the engineering course always followed general collegiate studies, the principles of art might be acquired at the same time, and their practical applications to engineering pointed out in the engineering school. As it is, an attempt is being made to give young men, and in many cases mere boys, a course in engineering and a part of a general college course at the same time, to the greater or less detriment of both courses. We are well aware that there are many reasons for this practice, some of them most excellent, and that otherwise hundreds of engineers to-day would have had no part of a general college training.

But we still contend that for the broad success at which all students aim some fundamental artistic training is essential to all, whether the later chosen profession in life is engineering or any other branch of science or the arts. It is a part of the early mental equipment that is too often neglected, though it is, or should be, a potent factor in both our practical as well as esthetical life.

LETTERS TO THE EDITOR.

Proposed Standard Specifications for Portland Cement.

Sir: In your issue of July 16 appears an interesting review of the standard specifications for Portland cement, proposed by Mr. Wm. J. Donaldson. The need of such a system of standard requirements is certainly very great, as must be apparent to any one who has had occasion to study the extremely variable specifications drawn up from time to time by government engineers. Such a set of official requirements would also serve as a standard for private practice, and would be of inestimable value and convenience to engineers and cement consumers. Mr. Donaldson certainly deserves great credit for having taken the initiative in this important matter, and it is greatly to be hoped that the subject will be taken up by government and private engineers, and an agreement arrived at. It would help the matter along most decidedly if the American Society of Civil Engineers would attack this question anew, and establish a series of cement tests in keeping with modern practice in other countries. The recommendations of the Committee of the Society (1885), are very general and indefinite, and fail to supply the clear and exact rules necessary for uniform work and reliable results. Most other nations have distinct official requirements, which agree, in general, with each other in important matters. Those of Germany undoubtedly represent more careful study and experiment than those of any other country. For many years committees of the Association of German Cement Manufacturers have worked in connection with the officers of the Royal Experiment Station to perfect these official requirements and they consequently embody the latest information which is to be had on the subject.

The writer supposes Mr. Donaldson's recommendations in regard to detailed requirements to be intended chiefly as suggestions, and is not therefore disposed to criticise closely the specifications or methods of tests proposed. A few defects in the specifications given may, however, be briefly pointed out.

Quality.—The requirement that cement should be exposed to air for 30 days before shipment is a new one, and in the opinion of the writer, unnecessary. Well-made cement should be perfectly sound when fresh from the mills. Bad cement may often require several months of seasoning before it is fit for use. The question of soundness can be tested in other ways, and a certain length of time of seasoning is no guarantee of good quality.

Chemical Composition.—A requirement that the cement shall contain lime, silica and alumina within certain limited percentages, seems to the writer to be superfluous and misleading. The limits, if established, must be very wide, and if so, are useless. For given materials the proportions must be nearly exact, but different materials yield cements of widely varying composition. The cause of this difference is chiefly the varying composition of the clays used, a silicious clay requiring far more lime than an aluminous one. Mr. Donaldson's requirement for silica (20 to 22%), is especially narrow, and would exclude Dyckerhoff and the cement Mr. Donaldson is himself interested in manufacturing, which, according to analyses made in the writer's laboratory, showed respectively 19.35 and 22.5% silica.

Fineness.—The proposed requirements of 95% through a No. 100 sieve, and 80% through a No. 200 sieve, are out of all reason, and would exclude more than nine-tenths of the best German and American cements. Within the past month the writer has tested samples of the cement in which Mr. Donaldson is himself interested, obtained from dealers in several of the larger cities, and none of these samples come anywhere near passing these requirements. There are few, if any, cements now on the market which show over 90% through a No. 100 sieve. What the fineness on No. 200 may be the writer cannot say, as he has never seen a correct No. 200 sieve, and doubts if one exists. Samples of best foreign wire cloth proved to be 184 × 187 mesh, and very uneven, when examined under the microscope. None of the leading brands of cement, German or American, showed over 70% through this sieve. The time will doubtless come when a higher degree of fineness will be demanded by the trade. The introduction of the tube-mill is making it possible to obtain such a degree of fineness as Mr. Donaldson describes. From tests of American and foreign cements now in the market, however, it does not appear that the tube-mill has found extensive use up to the present time. In the opinion of the writer, a requirement of 90% through a No. 100 sieve is amply sufficient. This requirement will exclude most English and many German cements, while the leading brands of American cement will pass it satisfactorily.

In all requirements for fineness, the gage or diameter of the wire, as well as the number of meshes, should be distinctly specified, as variation in this respect will make an immense difference in the results. The German official requirements specify that 90% shall pass a sieve of 76 meshes to the linear inch (900 per sq. cm.), in which the diameter of the wire is one-half the width of the opening.

Test for Checking and Cracking.—The writer finds that exposure of the pats to hot steam (after setting over night), instead of placing them in boiling water, gives more satisfactory results. Five hours in hot steam (200° F. or over) will be found sufficient to detect the slightest tendency to expand or crack.

Specific Gravity.—This test is of little value, since even unburned cements usually show a specific gravity of at least three, and the increase due to perfect burning is extremely slight.

Setting.—The temperature of the room and of the water used should be specified, as these exert an immense influence on the time of setting. The pats should also be kept in damp air in a closed metal box. The proportion of water used should also be such as to give a constant consistency, both for tests of setting and tensile strength. The German requirement is that the proportion of water shall be such that when a quantity of the paste is placed on a plate of glass, several taps on the slab will be necessary to cause it to spread to the edges. This may seem a rude method, but practical trial will show it to be simple and fairly definite.

Tensile Strength.—Much more uniform results are obtained by filling the molds, then turning them over and filling again from the other side.

A requirement of a certain strength at one day is very objectionable. Nearly all well-informed engineers have abandoned the practice of making one-day tests.

The mixture for briquettes should be worked a certain definite time. Three minutes is a good minimum. Sand briquettes must be pounded into the molds to give uniform results. The German requirements specify that this shall be done with a spatula of certain size and weight. The writer has obtained the best results by filling the mold above the top, then laying a small block of wood over it and pounding lightly with a mallet, repeating on the other side.

The amount of water for sand tests, as proposed by Mr. Donaldson, namely, one-half the amount used for neat tests, will be found rather high. The Germans use 10% of water for sand tests, 1 to 3, with all cements. Neat tests will generally require 22 to 25%.

The use of crushed quartz instead of sand seems to the writer very objectionable. The Germans use a normal sand, 20 to 30 mesh, from Freienwalde on the Oder River. This shows about 33% of voids, while American standard crushed quartz of the same fineness showed 50% of voids. The quartz is in the form of glossy splinters, while the sand is made up of roughened grains. For these reasons the quartz gives much lower tests than a pure sand, and the results are less indication of the way the cement will work in practice. The crushed quartz is also very costly (about $10 per barrel), an important consideration where many tests are to be made. There is no reason why a good quartz sand, from some one locality, should not be adopted as a standard in this country.

In spite of the above criticisms, it should be said that Mr. Donaldson's suggestions are, on the whole, extremely good, and show careful study of the subject. It is earnestly to be hoped that they may lead the way to further discussion, and to the adoption of a definite standard of cement-testing in this country. S. B. Newberry,

Manager Sandusky Portland Cement Co.

Sandusky, O., July 30, 1896.

Sir: In your issue of July 16, 1896, you give several columns of your valuable space to a "Proposed Standard Specification for Portland Cement," by Mr. W. J. Donaldson, of Philadelphia, the object of which is "to urge the adoption by the United States of a standard specification for Portland cement, the use of which should be required on all work done under the direction of the officers of the Corps of Engineers, and also by the Navy, the Supervising Architect's office, etc."

The formulation of such a specification seems to be a pretty large piece of work for one man to "go it alone" on, and its publication even, by so well considered a scientific journal as your own, may lead to serious results by its use without examination by those who have not perceived its errors and inaccuracies.

The matter of the making of specifications is a grave one. In Germany, committees of the Cement Manufacturers' Association, acting with government co-operation, have been sitting for three years awaiting the results of experiments before merely recommending changes in recognized standards; in France, the Commission des Methodes d'Essai des Materiaux de Construction was constituted in 1891, and did not report until 1893; in this country our American Society of Civil Engineers was several years considering its specifications for cement, and since their adoption in 1885 has made no changes. So that, broadly speaking, the scientific and engineering world, knowing how much the question of reputation of engineers, architects, contractors and even cement manufacturers is involved in any new specifications for cement, or even any change in the same, has ever been slow to recommend and ever slow to adopt new rules or changes in normal standards. Why, therefore, it should have remained for Mr. Donaldson to formulate of his own motion this radical departure from old landmarks, he best can explain; but to those of us engineers or associated with engineering societies here and abroad, it seems to partake of foolhardiness, unless by reason of long experience, great knowledge or deep scientific thought and authority, he can justify his action, or unless his cement has been rejected on present government specifications (Dist. of Columbia, 1895), and he proposes in the future to "make the punishment fit his crime" alone. The proper way, however, to consider such a matter, would seem not to jump off at a haphazard guess or opinion as to what sort of a specification would suit any one cement or class of cements, but to look carefully into the history of Portland cement, its methods of manufacture, its uses, its results on works and the accepted standard specifications of the world before laying down any arbitrary rules.

Now, the use of Portland cement in a large way dates back to the time when John Grant first began to adopt it on the London sewers, and his book, published in London by E. & F. N. Spon, in 1875, gives a summary of his papers read in December, 1865, and April, 1871, before the Institution of Civil Engineers in London. It was an outcome of the tests then described, and of the bold use of cement thus mentioned, that engineers began to have faith in Portland cement, up to that time an article of doubtful engineering utility. Following Grant, the French and German engineers began to employ large quantities of Portland cement, and in the latter part of 1880 it came to be largely used here in America for engineering work; though it was used prior to that for paving. Therefore, as engineering and architectural faith rests on Portland cement, so far as permanence and durability are concerned, on these uses abroad, it behooves him who would make specifications to consider first what were the methods of manufacture in use in England when Grant was working and what requirements he had for Portland cement and what results he obtained. It would be also his duty were he minded to be fair and candid to follow this up by an examination of the figures of Mr. Reginald E. Middleton, published in "The Engineer," Vol. 65, p. 279 (London), giving records of long-time tests on a number of various cements which gave varying results at seven days. It would next become necessary for him to examine the long-time tests of the New York Aqueduct, of the Niagara Tunnel and other large work in this country, and then he would be in a suitable frame of mind judicially to consider the question. To such an one, it would appear that all the Portland cement on which long-time tests by engineers or other unbiassed parties have been made and published, and thereby have become engineering authority, have been cements made in Europe or America by the same methods practically as the cements used by Grant. Clay and chalk, limestone and clay, marl and clay, argillaceous limestone and limestone, have according to their chemical constituents been ground together either wet or dry, and either with the water they contain or with water added, have been made into a mud (slurry) or bricks containing the requisite chemical ingredients of lime, silica and alumina in finely comminuted particles. In every case the result has been to make a new stone, brick or block with the finely subdivided grains of the several chemical ingredients; artificially rearranged and in close mechanical union for the action of the fire of the kiln. In every case these bricks or blocks have been burned in closed or continuous kilns where the material was brought into close contact with the flame of coke or coal, and the uniform distribution of fuels in layers through the mass has caused uniform burning and clinkering. In every case the resultant powder, caused by grinding the clinker, has been shipped to the consumer without the addition of sulphate of lime incorporated with it after grinding, to give it fictitious strength and most dangerous qualities. So much for the process of manufacture, and on this point it seems clear that if engineers and architects are to rely in their work on the experience of other engineers, they should know what process the cement they are offered is manufactured under, and if it varies from the established standards which have given the standard results, on which our knowledge of cements rests, then as a prime requirement of any specification "proposed" or otherwise, the mode of manufacture and the long-time tests of the cement offered should be considered and inquired into regardless of abnormal 7 and 28 day tests and other similar data.

In order to go over the "proposed" standard specification of Mr. Donaldson, I have taken considerable trouble to gather together the leading specifications of this country and Europe, for purposes of comparison and also for the purpose of emphasizing what the world of engineers and not one cement manufacturer alone thinks on this important subject. Some of these specifications formed part of my contribution to a discussion before the Engineers' Club, of Philadelphia, and others recently gathered show a marked swing in the pendulum in favor of the elimination of boiling tests and other uncertain methods, and also in favor of much lower tensile strains, neat at 7 and 28 days.

Taking up the Donaldson specification in detail no careful manufacturer would object to seasoning his cement as this is common practice but why a manufacturer should under Clause 2 furnish "certified tests from the laboratory on every car furnished, which shall in no wise be a guarantee of acceptance by the government, as acceptance or rejection will be made on government tests"—is beyond explanation and seems a work of supererogation. So far as the clauses relating to packing and sampling are concerned they are not new and therefore are unobjectionable.

The matter "of a chemical composition" is too serious a one to lay down arbitrary rules about which would exclude nearly all of the cements used in Europe and America by the best engineering talent for years past. Mr. Donaldson's figures are as follows:

Lime, 62 to 66%.
Silica, 20 to 22%.
Sesquioxide of iron and alumina, 8 to 12%.
Magnesia, not over 3½%.
Sulphuric acid, not over 2% for slow setting cement.
Sulphuric acid, not over ½ of 1 % for quick setting cement.

The proof of the absolute unreliability of such a chemical requirement, as that submitted, is best shown by reference to Candlot's "Ciments and Chaux Hydrauliques," Baudry & Co. Paris, 1891. On p. 76 this leading authority gives analyses of no less than 12 French, 13 English, 6 Belgian and 14 German Portland cements of commerce. Out of this total of 45, no less than 36 exceeded in silica, Mr. Donaldson's requirements; no less than 9 exceeded the requirements of alumina and iron; not a single one contains magnesia up to 3½% ;only 3 exceed 2% magnesia, and only 1 contains sulphuric acid up to 2%. As to the important element of lime, no less than 20 contain less than 62% of lime, and only 6 contain over 64% of lime.

Another eminent French authority, Professor Le Chatelier of the Ecole de Mines, Paris, in a paper read at Chicago, "Trans. Am. Inst. Mining Engineers, International Engineering Congress," August, 1893, p. 14, gives as composition of commercial cement of good quality, a material which would fall "outside the breastworks" of Mr. Donaldson's specifications, in the elements of lime, silica, magnesia and sulphuric acid. Still another, Feret, in his monograph on the addition of plaster (sulphate of lime), to Portland cement, "Librarie des Ponts et Chaussees," Paris, 1890, p. 67, shows conclusively that the presence of anything like 2% of sulphuric acid in cement to be used in salt water would invariably cause the disintegration of the mortar, and yet this point is entirely overlooked in these new specifications. Furthermore, so eminent an authority as Baron Quinette de Rochemont, Inspecteur General des Ponts et Chaussees, in his work on "Portland Cement at Havre," "Institution of Civil Engineers," London, Vol. CVII., 1891-92, p. 9, in describing the disintegration of certain cement,says the cement "now in its worst state" was "analyzed by the laboratory of the Ponts et Chaussees, and showed alumina and iron 9.80, and lime 62.95," or exactly within the lines proposed by Mr. Donaldson. The French government, in the marine service specifications, especially provides that Portland cement must not contain more than 1% of sulphuric acid. Cahier Guillain, Art. 6.

German authorities against such chemical requirements as Mr. Donaldson proposes, are equally weighty—Professor Tetmajer, of the Zurich Polytechnicum, a leading scientist, in his work on "Hydraulischen Bindenmettel," Zurich, 1893, gives on pp. 146 et seq. analyses of 88 German, Austrian, French and Swiss Portland cements, made by 16 leading European chemists. This list of cement includes such well known brands as Stuttgarter, La Farge, Mannheimer, Heidelberger, Dyckerhoff, Vervohler, Shifferdecker and De Grand Champ.

Out of the entire 88 cements, no less than 57 fall outside of the limits of silica, a large number contain alumina and iron in excess of 12%, and, as to lime, no less than 59 contain less than 62% of lime, and only 6 contain lime up to 64%. Of magnesia, only 7 out of 88 contain 3½%. Of sulphuric acid only 13 run up to as high as 1½% when the sulphate of lime (Ca S O_4) Tetmajer gives is reduced to its elements.

To a similar purpose may be quoted Dr. Preussing's table of analyses read before the German Cement Manufacturers' Association at their 1894 meeting (Berlin, Funcke & Co., 1894), where out of 24 cements analyzed only 14 had lime in excess of 62%; only one magnesia in excess of 2.68%, and not a single one had sulphuric acid up to 2%.

The English are no less positive in their chemical determination. Redgrave, "Calcareous Cement," London, 1895, p. 145, quoting Margetts' paper before London Institution of Civil Engineers, 1891, shows that none of the cements there mentioned would have met Mr. Donaldson's proposed specification.

When W. F. Reid wrote on "Portland Cement," Philadelphia, H. C. Baird, 1869, on p. 12 of Lipowitz' paper there printed, he gives analyses of eight Portland cements, not one of which fall within the requirements referred to, and not one of which contain magnesia up to 2½%. In the work by Henry Reid, the eminent authority, London, 1879, p. 50, the "good Portland cement" he gives an analysis of, would likewise have failed if tested by Mr. Donaldson. Another writer and engineer, no less than the late Henry Faija, of London, in his last paper, Trans. Am. Soc. C. E., Oct., 1893, p. 43, knew nothing of these new specifications when he described the elements of Portland cement, entirely outside of the new lines just published. The eminent engineer, Carey, in his paper, "Inst. Civil Engineers," London, Vol. CVII., 1891-92, p. 35, was in a similar state of ignorance when he described as a "good Portland cement" one which would not pass Mr. Donaldson's specifications.

So, too, was Collins in a similar state of darkness when he made his definition of an average composition of a "sound Portland cement" in his book, E. & F. Spon, London, 1888, p. 8.

So much for European authorities,who by reason of their longer use of Portland cement, might be supposed to know something about its chemical constituents; but even the weight of American authority is against Mr. Donaldson. The analyses of Dyckerhoff, Brooks, Shoobridge, Alsen and Giant Portland cement by the late Prof. De Smedt, the well-known authority and for many years Inspector of Cements, U. S. government (Rep. Dist. of Columbia, 1885, p. 47), show that each and everyone of these well-established brands would have been rejected under these new views of chemical elements. Furthermore, not one of them shows sulphuric acid up to 1%, and only 1, magnesia approaching 3%.

As for Prof. Spaulding, of Cornell, in his work published Ithaca, 1893, he is likewise wrong on p. 4, when he describes the requirements of a Portland cement, and the same may be said of Prof. Jameson, who, in his "Monograph," Iowa City, 1895, p. 4, lays down chemical elements outside of Mr. Donaldson's narrow bounds. Finally, to prove our new authority right and the older cement authorities wrong we must also overrule that distinguished writer, Gen. Gillmore, "Cements and Lime Mortars," New York, 1879, p. 65, in his analysis of Portland cement there published.

On the other side, therefore, we have the concensus of the world's authorities, of France, Germany, England and America; on the other side we have Mr. Donaldson. What weight should his opinion carry? What is his chemical and scientific reputation? His first work on cement: "Alpha Portland Cement," Donaldson & Co., Philadelphia, Allen, Lane & Scott Press, 1894, p. 4, contains a description of manufacturing Portland cement, and one paragraph is as follows: "The company find the rotary cylinder process the least expensive of any they can use, it being especially adapted for their raw material, as it is not refractory; the carbonic acid is readily driven off and is then easily ground to a fine powder."

On the strength of a chemical knowledge enabling one to grind "driven off" "carbonic acid to a fine powder," in the process of making cement, Mr. Donaldson may seek to overthrow the weight of the world's chemical opinion, but chemists will hardly permit it, and even he, himself, is doubtful about his own knowledge, for in his second book, the one now under criticism, the amount of magnesia is set down in print at 2½%, and then subsequently changed in ink to 3½%, and he likewise altered the time of setting by a communication to you of July 21, 1896, published July 23, 1896.

Is this, therefore, such a voice as we should listen to, an authority, which, without a single citation or fact, sets up a chemical standard contrary to that which scientists of world wide reputation have fixed, and by whose specifications anywhere from 80 to 90% of the cements of established reputation the world of engineering has been using from 30 to 40 years, would be excluded. On the face of his known chemical knowledge, as shown by his own writing, Mr. Donaldson is condemned.

As to fineness, Mr. Donaldson is again arrayed against the world's scientific opinion; though no careful manufacturer would hesitate to guarantee cement of the fineness he recommends, namely 95% on 10,000 mesh sieve and 80% on a 40,000 mesh sieve. From a careful examination of many specifications, in Europe and this country, the following seem to be the requirements for fineness.

Residue.

Belgium, 15% on a 5,800 mesh sieve (Genie Belge).

Germany, 10% on a 5,800 mesh sieve (Rules Prussian-German Society).

Switzerland, 15% on a 5,800 mesh sieve (Report Tetmajer, Zurich).

France, no fineness specification (Clahier des charges, Ponts et Chaussees), (or in Government Commission Report).

France, 5% on a 5,800 mesh sieve (recommended by Le Chatelier and Candlot, French Chemists).

Roumania, 12% on a 5,800 mesh sieve (government specifications).

England, 8% on a 2,500 mesh sieve (recommended by H. Faija, World's Fair Congress, August 2, 1893).

United States, recommendation American Society of Civil Engineers, June 27, 1893, says: "Cements of better grades are ground so fire that only from 5% to 10% is rejected on a sieve of 2,500 meshes per sq. in.

Under this recommendation are the following specifications in this country:

New York Aqueduct, 80% on a 10,000 mesh sieve.

City of Baltimore, 90% on a 3,000 mesh sieve.

Department of Public Works, New York, 90% on a 2,500 mesh sieve.

Pennsylvania R. R., 90% on a 2,500 mesh sieve.

U. S. government, Dist. of Columbia, 95% on a 2,500 mesh sieve.

U. S. government, District of Columbia, 85% on a 10,000 mesh sieve.

U. S. government, Supervising Architect, no fineness specified.

Niagara Falls tunnel, 80% on a 10,000 mesh sieve.

Reading Terminal, 95% on a 2,500 mesh sieve, 75% on 10,000 mesh sieve.

U. S. government, Board of Engineers, 95% on a 2,500 mesh sieve.

City of Philadelphia, 90% on a 10,000 mesh sieve.

City of Philadelphia, 70% on a 40,000 mesh sieve.

New York Central R. R., 97% on a 2,500 mesh sieve.

Under the head of Cracking and Checking volumes might be written on the subject of hot tests or boiling tests and no conclusion arrived at; no two sets of scientists, no two sets of engineers, no two sets of experts have yet been able to agree as to these tests, their utility and their practical methods of use. The last report of the committee of the German Association of Cement Manufacturers presented at the 1896 meeting on this subject asks until 1898 to report, and meanwhile the normal cold water tests remains unassailed. On the other hand, the French commission, above referred to, recommends a moderate boiling test for slow-setting cement only, and this only in a tentative way. On this point the consensus of opinion all over the world seems to be against Mr. Donaldson and his recommended violent boiling test. It may be summed up as follows:

Germany—After three years' discussion, the boiling test was finally reported against at the session of 1893, by the German Cement Association, operating in conjunction with the Prussian Minister (Gary's paper, World's Fair Congress, Aug., 1893; Trans. Am. Soc. C. E., Oct., 1893, p. 13), and subsequently a committee to further investigate was appointed.

French Government—Conference of engineers Ponts et Chaussees, Cahier Guillain, Service de la Marine, Service de Colonie. None of these contain boiling tests. The French commission report is above referred to.

England—Faija's paper, World's Fair Congress, Aug. 2, 1893, Trans. Am. Soc. C. E., Oct., 1893, p. 59, recommends steaming tests only, and immersion at 116°, and requires no boiling test, which he admits he has abandoned as unreliable, though first proposed by himself.

United States—U. S. government, District of Columbia, specification, 1896, abandons boiling test. F. H. Lewis (Booth, Garrett & Blair testing laboratory), Philadelphia Engineering Club, Vol. XI., 5, 1895, p. 345, abandons boiling as "unreliable in indicating quality of cement." Am. Soc. C. E. specification recommends cold water and air tests only.

Under the head of tensile strength, Mr. Donaldson again runs his head against the requirements of the leading authorities here and in Europe. He requires:

Neat briquettes shall stand a minimum strain per sq. in. 12 hours in air, 12 hours in water, 200 lbs; 1 day in air, 6 days in water, 500 lbs; 1 day in air, 27 days in water, 650 lbs.; and briquettes of of 3 sand and 1 cement: 1 day in air, 6 days in water, 150 lbs.; 1 day in air, 27 days in water, 250 lbs.

In order to show the absolute inaccuracy of such specifications, I have gathered in Europe and this country the principal specifications for purposes of comparison, and there will be found below, a summary of requirements and tests under the branch of testing. In the case of European specifications, kilogrammes and centimeters have been roughly reduced to pounds and inches.

Neat Tests.

	7 days. lbs.	28 days. lbs.
France	284	497 (Cahier Guillain)
Russia	255	(Russian public works.)
Belgium	255	497 (Genie Belge.)
England	350 (Faija)	550 (Carey.)
Germany	No neat requirements.	

American Society of C. E. (250 to 550 lbs. at 7 days, 350 to 700 lbs. at 28 days tests recommended).

Under these recommendations are the following American specifications:

	7 days. lbs.	28 days. lbs.
U. S. Govt., Lighthouse Engineers, 1893	400	...
U. S. Govt., Army Engineers, 1893	450	...
U. S. Govt., Supervising Architect	300	...
U. S. Govt., District of Columbia, 1895	400	500
City of Philadelphia	450	550
City of New York	300	...
City of Baltimore	400	...
New Croton Aqueduct	300	400
Niagara Falls tunnel	300	400
Pennsylvania R. R. Co.	303	412
New York Central R. R.	300	500
Reading Terminal	350	...
Baltimore & Ohio	300	...
Lehigh Valley R. R.	300	...
New York city, Third Ave. bridge	300	500
Metropolitan R. R., New York	300	...
East River bridge, N. Y. (A. Corbin's)	303	...
City of Brooklyn	400	600
U. S. Govt., Lighthouse Engineer, 1896	300	...
U. S. Govt., Army Engineers, 1896	350	...
U. S. Govt., District of Columbia, 1896	375	500

Sand Test—(3 sand to 1 cement).

	7 days.	28 days.
France	...	215
Germany	...	227
Russia	...	142
Belgium	...	215
England (Carey)	...	200
Am. Soc. C. E. recommends	80—125	120—200

Under these recommendations are the following specifications:

	7 days. lbs.	28 days. lbs.
U. S. Govt., Lighthouse Engineers	100	...
U. S. Govt., Army Engineers, 1894	125	...
U. S. Govt., District of Columbia, 1895	100	150
Niagara Falls tunnel	90	...
New York aqueduct	100	...
City of Baltimore	...	150
City of Philadelphia	160	220
U. S. Govt., Lighthouse Engineers, 1896	80	...
U. S. Govt., Army Engineers, 1896	100	...
U. S. Govt., District of Columbia, 1896	125	175

These records all show modern requirements at 7 and 28 days neat, and a swing of the pendulum on the part of government engineers towards lower neat tests.

The reasons for this have been briefly set out in the early part of my letter, as following in the line of the long-time tests of John Grant, of the London drainage, above referred to. His figures from his papers above quoted are as follows; on a section of 2¼ sq. ins. (not 1 sq. in. as now practiced):

Age.	Neat cement. lbs.	1 cement to 1 sand. lbs.
7 days	817.1	353.2
1 month	935.8	452.5
3 months	1,055.9	547.5
6 months	1,176.6	640.3
9 months	1,219.5	692.4
12 months	1,229.7	716.6
2 years	1,324.9	790.3
3 years	1,314.4	784.7
4 years	1,312.6	818.1
5 years	1,306.0	821.0
6 years	1,308.0	819.5
7 years	1,327.3	863.6

These figures, which show about 350 lbs. per sq. in. at 7 days neat corroborate in their long-time continuing gains, the results of tests of cement now used by the New York Aqueduct under a specification of 300 lbs. at 7 days neat.

New York Aqueduct Tests. ("Trans. Am. Soc. C. E.," March. 1893, p. 191.)

Age.	Neat cement. lbs.	1 cement to 2 sand. lbs.
7 days	348	166
1 month	422	280
3 months	540	364
6 months	634	468
9 months	638	468
12 months	682	490
2 years	694	564
3 years	736	680
4 years	771	674
5 years	840	700

That a 300 to 350 lbs. specifications at 7 days neat will give good results the writer thinks is amply substantiated by the figures above given, and this is further corroborated by a paper read a number of years ago before the Institution of Civil Engineers, London, by Mr. Reginald E. Middleton (quoted above), where taking a series of cement tests that had broken at figures between 240 to 300, 300 and 350, 350 and 400, 400 and 450, 450 and 500, and 500 lbs. and over at 7 days neat, he found that those in the first three classes gained largely for a period three years and over, while those in the last three classes showed in the first two cases a slight gain, while in the other case a marked falling off at periods of three years and over, thus proving conclusively that such a specification as Mr. Donaldson recommends of tests of 500 lbs. at 7 days would lead to dangerous results in work.

On the whole, therefore, Mr. Donaldson's specifications may be divided into two classes of subjects. Those which are true are not new, and those which are new are not true.

But for the harm, the expression of such crude and ill-digested specifications as these to the community at large by their publication in scientific journals and their subsequent possible use by inexperienced engineers and architects I would not have trespassed on your columns to such length, nor have gone into so exhaustive an analysis of Mr. Donaldson's paper. It is to prevent this possible harm that I have written and I trust you will pardon the necessary length of my communication.

Robert W. Lesley,
Assoc. Am. Soc. C. E.
22 South 15th St., Philadelphia, Pa., Aug. 7, 1896.

(In accordance with our usual custom we submitted proofs of the above communications to Mr. Donaldson, who has replied as follows:)

Sir: The writer begs to apologize for the delay in answering your favor of the 18th ult., and replying to criticisms enclosed from Prof. S. B. Newberry and Mr. Robt. W. Lesley, as he has been away from the city for several weeks. Taking up the discussion of Prof. Newberry, the writer is pleased to note that this capable authority on cement agrees with him on the importance and need of formulating new requirements, and adopting a more specific system for the testing of Portland cements. Referring to his criticism on quality, to which it is proposed aeration for thirty days, the writer would state that this provision was not made as a guarantee of good quality, but rather to properly regulate the time of setting.

The criticism on chemical composition appears to be well founded. There have been, however, so many specifications drawn up lately, giving the limits of the various elements, showing the wide divergence of opinion on this subject, that it appears necessary to call attention to this and invite discussion. The writer agrees with Prof. Newberry that different raw materials will yield cements of different compositions, for, as he says, the varying composition of clays require different treatment, but would it not be well to establish limits for the several constituent elements and not have so many widely varying limits, which appear to be misleading? Such limits would detect any base properties, or adulterants in the cement. In the requirements for lime, silica, alumina and iron, although narrow, the writer bases his requirements on the average results of the analysis of the best German, French and American brands, with a few Belgian and English cements. Only the highest grade of tri-calcic silicate cements were considered. For magnesia, the reports of the Commission appointed by the German cement manufacturers to investigate the effects of magnesia on cement, made at frequent intervals, in the series of investigations, have gradually increased the permissable percentage since 1891, and in the last report, February, 1895, Drs. Schott, Meyer and Arendt, report the presence of magnesia up to 10% caused no harmful expansion, or cracking even after seven years. Dyckerhoff, as a minority, reported no change with magnesia up to 3%, but recommended the continuance of the allowable 5% limit of the previous year. The Commission agreed to continue the 5% limit, and make further experiments which would show whether a higher limit would be advisable. In the sulphuric acid requirements the writer has been guided solely by the experiments of the German cement manufacturers.

Adhering to the specific gravity test, the writer still thinks this important, as exposing slag and ground silica in adulterated cements, and not so much as determining the relative or apparent density. As to the fineness, the writer's sole intention in establishing such high limits for the No. 100 and No. 200 sieves was to increase the intrinsic value of the cements, and thereby to increase its effectiveness in the work. The prime object in grinding a Portland cement is not only to increase its adhesive strength, but what is of more importance, to cause the mortar to attain its maximum strength in the shortest possible time, which is being looked upon as a principle in high engineering work. From actual experience it has been shown in some of our leading cement manufacturing establishments, there are other mills besides the tube mill capable of producing such a high degree of fineness. Although experience has shown the number of meshes per square inch will vary in a No. 200 sieve, Prof. Newberry is correct in saying that the gage of the wire, as well as the number of meshes to the linear inch, should be specified. The writer has seen and obtained determinations for fineness on a No. 200 sieve, having 200 meshes per linear inch; such a sieve is to be found in the testing laboratory of Messrs. Lathbury & Anderson, Philadelphia. Sieves which do not show 200 meshes to the linear inch are not No. 200 sieves, and if so designated are incorrectly marked by the manufacturers.

In the matter of setting, although the temperature of the air and water do exert an influence on the cement, the writer does not think that in a laboratory, abnormal ranges of temperateure, which would materially affect the cement, are likely to occur. It might be well to specify 70° F. for the water, but as to the air, the influence being much less, the writer does not think, in view of summer heats, a limit could be specified. The provision specifying 24-hour tests was made in order to regulate the manner and method of performing same, in view of the various methods put forward in each case where it is specified. Personally the writer is opposed to this test, and thinks seven days the shortest time that should be specified. Recently on quite a large contract, the writer noticed the provision which called for the 24-hour test on Portland cement, one hour in air and 23 hours in water. A Portland cement of this character is inferior in quality. If, as Prof. Newberry suggests, a good quartz sand could be obtained, from some locality and in sufficient quantities, to supply the testing laboratories, in view of the great cost of crushed quartz, it might be well to specify it as standard, instead of crushed quartz. The chief consideration being a uniform sand, which necessarily will give uniform results.

After carefully reading Mr. R. W. Lesley's discussion on standard specifications for cement, the writer was much surprised by its tone, for, instead of being a criticism on technical lines, it delves into personalities wholly unsuited to the high scientific character of your valuable paper. As presumed by Prof. S. B. Newberry, in his interesting criticisms, the writer had no intention to "go it alone" on a subject requiring such careful consideration and deep scientific investigation as the adoption of a new and standard specification for Portland cements, but rather to present the subject in the light of suggestions and thereby open up the scientific discussion which would naturally follow. It is a well-known fact that the recommendations of the committee of the American Society of Civil Engineers are indefinite and altogether incapable of producing uniform results. The requirements are, on the whole, too low and inadequate, which allow of second grade cements going into work where the highest grade Portland cements are intended.

Mr. Lesley has always advocated low standards, following out the English ideas on the subject. Naturally to sustain his argument he introduces the wholly irrelevant subject of the history of Portland cement in England and cites certain well known authorities in that country whose opinions at best are hardly to be considered abreast of the times. It is generally conceded that the continental countries, notably Germany, have made more rapid strides in the investigation and manufacture of cements than in England where Portland cement had its birth. In the conventions held in Munich, Dresden, Berlin and Vienna to promote the adoption of uniform standards and methods for the testing of structural materials, the proceedings of which have been published by Prof. J. Bauschinger, of Munich, and later translated by Capt. O. M. Carter, Corps of Engineers, U. S. A., and Mr. E. A. Giessler, U. S. Assistant Engineer, it appears that the only country conspicuous by its absence was England.

The investigation of the results of long time tests, made on important engineering works in this country, as suggested by Mr. Lesley, would undoubtedly enter largely into the consideration of this subject, but it is doubtful whether any commission or body of experts appointed for such a purpose would pick out the only two works mentioned by Mr. Lesley, namely the New York aqueduct and the Niagara tunnel, admitting, as the writer does, the magnitude of those works, and draw their conclusions on a standard system from the performance noted on the one brand of cement used exclusively on the two pieces of work. As to the process of manufacture, entered into so largely by Mr. Lesley, it does not appear to the writer what connection it may have with the subject under discussion and his energetic defence of the method or "process of manufacture" would appear to the unbiased reader, as though he assumed that his methods of manufacture had been assailed and his equipment for grinding and burning the raw material had become obsolete and altogether incapable of producing a cement which would pass severe requirements drawn up to distinguish between the first and second grade Portland cements. Mr. Lesley apparently overlooks the progress made in the manufacture of Portland cement, and the improvements made in the grinding machinery and methods of burning, all of which are adapted to the various conditions of the materials. With few exceptions the cement manufacturers in this country have made rapid strides and introduced new machinery which would facilitate and at the same time better their product. Taking up Mr. Lesley's criticism on the furnishing by the manufacturer of certified tests, which he characterizes as "work of supererogation," it would be well to explain that this provision was made for the purpose of acting as a guide to those using the cement, whether it was to be tested or not. Such a provision would prevent delays on the work in cases where the cement was to be tested, as from such manufacturers tests it would be shown at once whether the cement was unlikely to pass the prescribed tests.

As to the criticisms on the "chemical composition," the writer has explained his purpose most fully in the discussion by Prof. Newberry, but it might be well to add that the changes noted and made so much of by Mr. Lesley, in the magnesia was a typographical error in the first pamphlet printed. It read 2½% magnesia and should have been 3½% magnesia. Mr. Lesley is wrong in saying that no provision is made for cement to be used in salt water. The second provision for sulphuric acid, calling for ½ of 1% was inserted to cover this contingency.

Throughout Mr. Lesley's discussion appears a vein of facetiousness which is wholly in keeping with the character of his criticisms on such a scientific subject as cement. It appears to the writer unprofessional, claiming as he does to belong to the engineering profession, to question one's reputation in the most insulting language. It appears like a similar attack Mr. Lesley made on Capt. W. W. Maclay some years ago, when the latter gentleman was engineer of the department of docks, New York, and in which he questioned the ability of Captain Maclay to correctly translate an article written in French on the subject of cement. No attempt has been made by the writer to place his authority on this subject against those well known authorities of the world as stated by Mr. Lesley. The subject was brought up for discussion and even Mr. Lesley, "Assoc. Am. Soc. C. E.," is welcome to criticise in the spirit of scientific investigation. The ludicrous attempt of Mr. Lesley to twist the meaning of a sentence in the small pamphlet by the writer of "Alpha Portland Cement," and cited in detail by Mr. Lesley, seems too childlike to answer, but for his benefit it might be well to explain that it was a typographical error in the punctuation.

Under the head of "Fineness" the writer is pleased to note that Mr. Lesley concedes the fact that manufacturers could guarantee the fineness specified and simply cites old specifications to show that no such high requirements were ever asked for, notwithstanding the fact that it is now the best practice among engineers to specify the finest ground cements. The value of fine grinding is known and why should the manufacturer not better the product by almost eliminating the coarser particles which only act as so much sand in the mortar composition.

Mr. Henry Faija, "Portland Cement for Users," London, 1890, says: In the manufacture of Portland cement it is impossible that the clinkers should all be burned to an equal degree of hardness, and in passing through the mill stones it is the softer pieces, or those which have received the least calcination, that are ground finest. and the thoroughly and well-burned clinker is only reduced to granules, not to powder, and as it is the best burned clinker that will produce the best cement, the value of fine grinding of the well-burned clinker is apparent." The writer admits that by increasing the fineness you thereby increase the cost of manufacture and it may be this item which influences Mr. Lesley's criticism on higher standards.

Upon the subject of hot tests Mr. Lesley brings forward authorities who condemn the reliability of this test; but taking up the first country, Germany, he admits that investigations are still being made on its reliability and in the meantime the test is still made. Although Mr. Lesley cites the French Commission's report, conference of engineers Ponts et Chaussees, Cahier Guillain, Service de la Marine, Service de Colonie, in which the "boiling tests" are not included, he does not indicate any of the well-known French authorities as being opposed to this test. In the paper of Prof. H. Le Chatelier, "Tests of Hydraulic Materials" read before the International Engineering Congress, Chicago, Aug., 1893, p. 31, under the heading, "Conclusion," this expert says: "For practical tests, it may be sought to accelerate and exaggerate the expansion due to the slaking of lime. For this purpose it is sufficient to elevate the temperature. If the briquettes, as soon as they have set under water, are plunged into boiling water, the swelling takes place in a few hours, instead of many days, and is besides considerably exaggerated. The products which when cold merely crack disintegrate when hot; those which swell cold split hot; and those which contain too little lime to swell cold do so very distinctly when treated hot. . . . . This test for invariability of volume, when made cold has but little interest, since it detects only exceptionally bad products." Thus it is seen that so eminent an authority as Prof. Le Chatelier, whom Mr. Lesley quotes on other points, thoroughly believes in the "Hot Test." For England he quotes the paper read by Mr. Henry Faija before the International Engineering Congress, Chicago, Aug. 1893, who, although he does not reject the steam vapor or hot-water tests, immerses the specimens in water at a temperature of 116°, thereby showing that he must still have faith in the hot-water test. In quoting his American authorities he states that "U. S. Government, District of Columbia, specifications, 1896, abandons boiling test," without stating on whose recommendation or authority. Next, Mr. F. H. Lewis, of Booth, Garrett & Blair, Philadelphia, who in conjunction with Mr. Edward Whitfield, also of the same firm, made a few experiments on the hot-bath test covering a period less than one year and drew their conclusions from the results obtained. This paper, read before the American Society of Civil Engineers in 1894, appears to be the only contribution on cement literature furnished by Mr. Lewis, whom Mr. Lesley quotes as an authority. From a brief summary of the above it will be seen that the Germans, French and English authorities still adhere to the hot test, while the only two doubtful authorities are quoted for the United States.

Such well-known authorities in this country as Captain W. W. Maclay, Professors Newberry, Spaulding and Sondericker still advocate the hot test. Mr. Lesley has always combated this test for possibly the reason that he desires to protect a certain class of cements which cannot meet this requirement.

Taking up the consideration of tensile strength, the writer cannot agree with Mr. Lesley in advocating such low standards. While recognizing the fact that abnormally high tests at short periods of time are not to be desired, the minimum limits advised by the writer are not considered high under scientific testing in well-equipped laboratories, following out societies' rules and regulations. The two principal reasons favoring high tensile requirements are: 1st. In order to keep out inferior and low grade cements. 2d. Maximum strength in short periods of time. Taking up the first reason, laboratory results show that all the best brands of both foreign and American Portland cements will meet the requirements advocated, while the doubtful brands are unable to develop such strengths in the periods of time allotted. Not only the second grade Portland cements, both foreign and domestic, are capable of passing the low requirements of strength in all the European countries and America, as quoted by Mr. Lesley, but even the so-called "Improved" cements, manufactured at some of the American mills and which are neither Portland or Rosendale cements, can pass them. 'Tis true that some of these low grade cements would fail in other requirements than the tensile test, but why should they not be barred in this respect? Considering the second reason, engineers at the present time demand a cement which when used in concrete or mortar will develop a high strength in a corresponding short period of time. This demand has been caused by the rapid growth in this country of massive monolithic structures in which cement is used, and furthered to a greater degree by the necessity of rapid construction, which makes it imperative to concentrate massive weights on concrete footings and on masonry work where cement mortar is used. Rapid hardening coupled with slow setting is desired by engineers in both mortars and concrete. Fine grinding promotes this feature at the same time causing the cement to attain its maximum strength in the shortest period of time.

M. Candlot, "Strength of Cement," Paris, 1891, p. 100, says: "If we observe in a general way the progress in strength of cement gaged neat or mixed with sand, we see that there are two kinds of Portland. Some cements, which give rather low tests during the first period of hardening, finally attain great strength at the end of two months, or even a few years. Other cements, on the contrary, show a very rapid increase in strength, and their maximum is attained in a few weeks or a few months. Nearly all the cements of good quality belong to the second kind; in the first are found the cements of inferior quality.

It is quite evident that, even leaving out the question of quality in the cement, resulting from a more or less careful manufacture, it is preferable to use those cements which acquire a great hardness in a short time. It is always an advantage when the hardening of mortar is not too slow because the structure is thus placed in a short time beyond all dangers. In works in sea water, for instance, a rapid hardening is an essential condition. When testing the cement, the briquettes are kept in pans protected from all causes of deterioration, and this makes it possible for those cements of little strength at the beginning to attain ultimately their maximum strength. But it is not so in practical works, where many outside circumstances are unfavorable to the mortar, and may spoil it more or less seriously, thus preventing it from ever developing all its energy. A mortar will all the more surely attain its maximum hardness as its initial strength is greater.

It is often said that the cements which harden slowly acquire an ultimate strength superior to those cements which attain great hardness in a few days. This is what M. Bonnami has formulated in this way: "What is gained in initial strength is lost in final strength." This is probably true in the case of common cements which contain some ingredients capable of swelling in time, but it is not absolutely true in the case of Portland cements. Whether the hardening is rapid or slow, the final strength is always about the same. "The hardening is gaged neat or when it is mixed with sand. In the first case, the maximum strength is attained in a few months; in the second case the hardening goes on more slowly, and the maximum strength, it appears, is only attained after a few years."

Mr. Lesley cites many specifications, in which with one or two exceptions the requirements for both neat and sand tests are all much below those advocated by the writer. The majority are old specifications whose requirements were favored some ten years ago, when Portland cement as an industry was still in its infancy. No specifications are quoted among the number from such great users as architects. In the city of Philadelphia alone five of the leading architects, using large quantities of Portland cement, have specifications equally as high as those recommended by the writer. while the same can be said of architects in the cities of New York, Boston and Chicago. Mr. Lesley quotes U. S. Government Army Engineers and U. S. Government Lighthouse Engineers as having a single requirement for tensile strength and leads one to believe that cement must pass the same specifications when advertised for from any or all U. S. Engineer Offices. This is a misstatement of facts, for this is one of the principal reasons that led the writer to formulate the "Proposed Standard Specifications for Portland Cement." From the specifications of the U. S. Army and Lighthouse Engineers, nearly all of which are in the possession of the writer, it is to be seen that each has his own individual requirements, thus precluding any single standard requirements as Mr. Lesley leads one to believe. In some of these the requirements are above those recommended by the writer.

Considering the long time tests of John Grant, of the London Drainage Board, Mr. Lesley seeks to place them alongside of the tests made at the present time. They were valuable at the time they were made, but in view of the betterment in quality of all the German manufacturers and a few of the English, these results are useless as a means of comparison at the present time.

To those ignorant of the true facts, the exhaustive discussion by Mr. Lesley appears full of scientific merit. His advocacy of low standards and continued aggressiveness against higher standards are well known; but the writer cannot allow the statement in the latter part of his argument to pass unchallenged. He refers to the harm accruing from such "crude and ill-digested specifications as these to the community at large by their publication in scientific journals and their subsequent possible use by inexperienced engineers and architects." In all fairness to the public, would it not be well for Mr. Lesley to state in what manner the "crude specifications" would prove harmful to "inexperienced engineers and architects?" If Mr. Lesley was writing as a cement manufacturer instead of an "Assoc. Am. Soc. C. E.," possibly these same "inexperienced engineers and architects" might fancy Mr. Lesley was interested in a cement or cements which would not pass the writer's advocated requirements. Let us hope such is not the case and that Mr. Lesley will soon become a convert to the necessity of constantly increasing the quality of American Portland cements and likewise seeing the need of a more uniform and specific standard of tests in this country. Yours very truly,

Wm. J. Donaldson.

Philadelphia, Pa., Sept. 1, 1896.

◆

THE MINERAL WEALTH OF THE UNITED STATES.

From the fourth annual issue of "The Mineral Industry" of the United States and other countries, for 1895, the following abstract is made of some of the more prominent industries tabulated and discussed in this most valuable statistical publication:

The total value of the mineral and metal production of the United States, in 1895, was $678,000,734, an increase of $96,789,496, or 16.6% over the product for 1894. In this total the metals represent $240,617,370, and the non-metallic products, $43,383,364, including in the latter $5,000,000 for various unspecified products. The chief gain has been in the mining of coal and iron ore, in the production of coke, lime, petroleum, evaporated salt, copper, etc., and these gains, as compared with 1894, may be set down as follows:

	1894.	1895.
Coal, anthracite, short tons	52,010,433	58,362,985
Coal, bituminous, short tons	117,865,348	137,398,347
Iron ore, long tons	11,880,000	16,950,000
Coke, short tons	8,495,295	9,927,348
Lime, bbls.	56,750,000	60,000,000
Petroleum (crude), bbls.	48,527,336	50,652,025
Evaporated salt, bbls.	11,798,659	12,521,498
Copper, lbs.	353,504,314	386,453,850
Pig-iron, long tons	6,657,388	9,446,308

The amount and value of gold and silver produced, at the commercial value of the latter, are thus set down for the two years:

	1894.		1895.	
	Amount, fine ozs.	Value.	Amount, fine ozs.	Value.
Gold	1,923,619	$39,761,205	2,265,612	$46,830,200
Silver	49,846,875	31,403,531	46,331,235	30,254,296

In 1895, metals to the value of $29,593,543 were produced from foreign ores and bullion, including chiefly silver from Mexico, valued at $18,380,232, gold from British North America and nickel from the Ludbury mines in Ontario; the latter valued at $970,000. The amount of iron smelted from foreign ores is insignificant and not included, while it should be noted that the pig-iron product of the United States, for 1895, exceeds the highest record of any previous year, or 9,202,702 long tons in 1890. This advance again makes this country the leading iron-producing nation of the world; and taking our output as 100, the other leading nations would stand as follows: Great Britain, 79; Germany, 60, and France, 21. Our steel production was over 6,000,000 metric tons, of which approximately five-sixths were Bessemer and one-sixth open hearth steel. The total steel product was 20% greater than that previously reported for any one year.

In the relative importance of mineral products, coal stands first by a standard of value, with a total of 31.8% of the value of the entire mineral productions; and pig-iron holds the second place, with 16% of the total. Gold only represents 6.9% of the total value here referred to; petroleum is next, with 6.3%, and copper holds the fifth place, with 5.5%. Silver production represents only 4.5%, or less than the value of building stone, and but little greater than that of lime, in the column of total values. Among mineral productions petroleum and copper form our chief articles of mineral export. As a mineral producing nation the United States, in 1895, took the first rank as a producer of gold, iron and copper; Mexico exceeded it in the silver output, and Great Britain as a coal producer.

◆

TESTS OF A 300-HP. DE LAVAL STEAM TURBINE.

We have received through the courtesy of Mr. J. W. Lieb, Jr., general manager of the Edison Electric Illuminating Co., of New York, a copy of the results of the acceptance tests of one of the 300-HP. De Laval steam turbines installed in the Twelfth Street station of that company. The results of a six-hour test, made on April 2, 1896, during which independent readings of volt and ampere meters were taken by two observers every five minutes showed a water consumption of 19.275 lbs. per electrical horse-power hour, or 17.348 lbs. per brake horse-power hour, on the assumption that the commercial efficiency of the 100 K-W. dynamos driven by the turbine was 90%.

The turbine tested was one of two supplied to the Edison Electric Illuminating Co., of New York, by the Societe de Laval, both of which were built by the Maison Breguet, of Paris. Each 300-HP. turbine drives, by means of gearing, two 100 K-W. Desrozier's dynamos, one on each side of the turbine shaft.

Operating with a steam pressure of 145 lbs. per sq. in., and a vacuum of 26 ins. the guaranteed steam consumption, when operating condensing, was to be not over 18.7 lbs. per brake HP. hour. The turbine disk has a diameter of about 0.75 meters (29.5 ins.), and a thickness through the blades of about 10 mm. (0.4-in.). The disk runs at a speed of about 9,000 revolutions per minute; the dynamos at 750 revolutions per minute.

The total equipment, comprising steam turbine, gearing and dynamos, occupies a space 4.05 meters (13 ft. 3 ins.) long, 1.97 meters (6 ft. 5⅝ ins.) wide, and 1.31 meters (4ft. 3 ins.) high.

The tests were made under the supervision of Mr. J. Van Vleck constructing engineer of the Edison Electric Illuminating Co. and M. Pare, engineer of the Societe de Laval. The following are the principal results of the six-hour test:

	+ side.	— side.
Average volts	127.25	128.26
Average amperes	708.56	725.47
Deduct amperes field circuit	16.08	16.29
Net amperes	692.48	709.18
Average watts	88,118.10	90,959.40
Average watts, both sides	179,077.5	

This last figure is 90% of 198.475 watts, equivalent to 266.72 brake HP.; horse-power hours, 1,600.32; weight of water condensed and discharged by the air pump in six hours, 27.763 lbs.

Lbs. of water per B. HP. hour	17.348 lbs.
Lbs. of water per B. HP. hour.	19.275 lbs.

The uniformity of operation is shown by the five-minute volt and ampere readings. . The volts ranged during the six hours from 126 to 128.5, and the amperes from 672 to 765. The vacuum ranged from 25½ to 26 ins, averaging 25.74 ins; the temperature of the inlet averaging 79.7° F., and that of the discharge 103.5° F. The steam pressure averaged 155 lbs. in the pipe, 150 lbs. at the throttle, and 147 lbs. below the throttle. The temperature of the dynamos after the six-hour run was as follows:

	+ dynamo.	— dynamo.
Armature	120° F.	129° F.
Average of fields	98° F.	107° F.
Commutator	144° F.	132° F.
Temperature of room	82° F.	

On April 3 a series of tests was made of the turbine with different loads, when operated with 2, 4, 6 and 7 jets. The duration of each test was one hour. The following are the principal results:

	Average load —amperes—		Average —watts.—		P. c. of full load.	Vacuum.	Lbs. st'm. per E. HP.
	+	—	+	—			
2 jets used	153.78	147.15	18.707	18.283	18.50	27.00	27.35
4 " "	433.60	455.80	54.156	57.886	56.02	26.43	20.22
6 " "	700.85	718.65	87.746	91.268	89.51	26.07	19.75
7 " "	771.94	787.33	97.418	100.86	99.14	25.79	19.95

J. F. HOLLOWAY.

In our last week's issue we published a brief note of the death of Mr. J. F. Holloway, the news of which, without any particulars, we received just before going to press. We have since learned that he died at his summer home at Cuyahoga Falls, O., on the evening of Sept. 1. On Aug. 20, while in Buffalo, he took cold, which brought on an attack of congestion of the kidneys. After receiving medical advice to the effect that his condition was serious he hastened home, reaching there Aug. 22. From then until his death he was, for most of the time, in a semi-conscious state.

Mr. Holloway was born in Uniontown, O., Jan. 18, 1825. When about six years of age his father moved to the Western Reserve and built a house on the banks of the Cuyahoga River, where afterward grew the town of Cuyahoga Falls. He served an apprenticeship with the firm of Bill Brothers, engine builders, and then was employed in the shop of the Cuyahoga Steam Furnace Co., of Cleveland. He was for a time in New England, and afterward went to Cumberland, Md., were he was superintendent of a coal mining company for some years. Later he was several years at Shawneetown, Ill., as general manager of an iron and coal company, organized by Sellers & Co., of Philadelphia. About 1860 he returned to the Cuyahoga Steam Furnace Co., at Cleveland, where he remained for 26 years as superintendent and president. This works was one of the most noted of the west for the building of blowing engines for blast furnaces, marine engines for lake steamers and heavy engine work generally. After the death of the old owners of the works Mr. Holloway was its sole guiding spirit, managing it as trustee for the heirs. It was a shop of the olden time, dating from 1834, without the modern appliances considered necessary for heavy work, but nevertheless it continued to do its share of the heavy work for the west until 1886, when the plant was sold entire to the Cleveland Shipbuilding Co. One side of Mr. Holloway's finely rounded character is shown in the address he made to his men on the last day of the year 1886, when the shop was turned over to the new concern. We quote an extract, as follows:

> With the closing hours of this, the last day of the year, will come the end of the business of the Cuyahoga works within these walls and under my management. Among the many thoughts which have come to me at the end of over 25 years of my supervision of its business and of my personal association with you none gave me more concern than did the thought what will become of our long-tried faithful men. And nothing gives me more pleasure than the assurance I have received from the new owners that they intend to make no changes in this respect and that they hope every man will continue to occupy his place in the future as he has in the past. As I could not bear the thought that on this last day of the year you should go to your homes and to your families full of doubt and uncertainty as to what might be in store for you in the opening year, so I cannot bear to let this, the last opportunity I shall ever have of seeing you together pass without endeavoring to express to you my appreciation of the fidelity and honesty with which you have all done your part toward making the record of the Cuyahoga Works what it now is. For myself I want to say that working here as a boy and alongside of some who are now present, coming back later on to be your superintendent, and for many years past the president of the company as well, I have had many a difficult task to perform. While it was but just and proper that every man from the lowest to the highest grade should have all that he could earn, it was also necessary that I should have a regard for the interests of those whose money furnished you with employment, and who were entitled to a fair return for its use. Now that all this has come to an end, it is great satisfaction to know that during all these years there has never been a difference between the employees and the company that we could not and did not settle among ourselves, and I hope to the advantage of both.

After leaving the Cuyahoga Works in 1887, Mr. Holloway removed to New York, and was connected with the firm of H. R. Worthington, pump manufacturers, for seven years as consulting engineer. About two years ago he left this position and became consulting engineer for the Snow Pump Co., of Buffalo, N. Y.

Mr. Holloway was for several terms president of the Civil Engineers Club, of Cleveland; vice-president for two terms of the American Institute of Mining Engineers, and president for the year 1885-6 of the American Society of Mechanical Engineers, of which he was one of the charter members. He was also a member of the Engineers' Club in New York.

While Mr. Holloway was a constructing engineer of marked ability, and a most efficient manager of works, he is best known and will be best remembered by the profession for his remarkable charm of manners and of speech. He was a fluent popular speaker and a ready writer. Probably no member of the profession had a larger circle of intimate personal friends. Another ex-president of the Mechanical Engineers' Society in a private letter says of him: "I think he was the most lovable man I ever knew." The local members of the American Society of Mechanical Engineers at their meeting in Cleveland on Sept. 3 adopted a resolution regarding the personal loss of each of them, caused by Mr. Holloway's death, as well as the loss to the profession at large.. At the next monthly meeting of the Engineers' Club of New York on Oct. 1, addresses of tribute to Mr. Holloway's memory will be made by some of his friends.

A BICYCLE FIRE-ENGINE, propelled by cycling firemen, is being tried in Paris. The engine rests upon two tandem bicycles coupled together and having a single steering post. The engine is simply a rotary pump, operated by the men, and the machine complete, with hose, weighs "only 140 lbs." The pumping power is applied by raising the two hind wheels from the ground, by a supporting leg, coupling the pump to these wheels, and then placing two men in the saddles to do the work. The capacity of the pump is reported as being 4,500 gallons of water per hour, thrown 75 to 100 ft. into the air. It is to be chiefly applied in small towns or in the country.

THE GREENLEAF CENTER-BEARING TURNTABLE.

(With inset.)

The turntable, like all other permanent way and track structures on railways, has had to undergo a material modification in design and construction to suit the increased weight and size of the locomotives which modern traffic demands. In the earlier days of railways, and indeed up to the time not so very many years past, turntable design was not considered a serious problem. For the light weight engines of those times turntables of wood or a combined wood and iron construction amply served all ordinary purposes, for although their lives were short (usually from five to eight years only) they were comparatively inexpensive to repair and replace. The turntable of the present day is quite a different structure, for, constructed as it is of iron or steel from 65 to 70 ft. long and with a capacity of from 100 tons to 170 tons, it is necessarily expensive, and durability in respect to repairs and reconstruction is a very important feature. We find consequently a correspondingly greater attention being given by railway engineers to the careful study of structural principles and constructive details in all parts of such structures. A study of the drawings on our inset sheet with the following description of their more prominent features illustrates the fact very forcibly, and as we shall take occasion to show in a later issue, a similar careful consideration is shown by the work of designers other than the one whose design is illustrated here.

In turntable designing theoretical considerations have to be modified by empirical rules which experience has developed, and before describing the construction illustrated herewith some of these may be stated to great advantage. Theoretically a center-bearing, single beam construction is considered preferable. By this it is meant that the center bearing carries the entire weight of the table and its load leaving the end bearings free from load, and that the whole table acts as a single beam to resist strains. A moment's thought will show that if such a construction can be made theoretically perfect all the frictional resistance to turning is brought at the point where the greater leverage is available to overcome it, and that diagonal deflection with its various concomitant troubles is avoided. Of course, only a more or less close approach to either of these desiderata is possible.

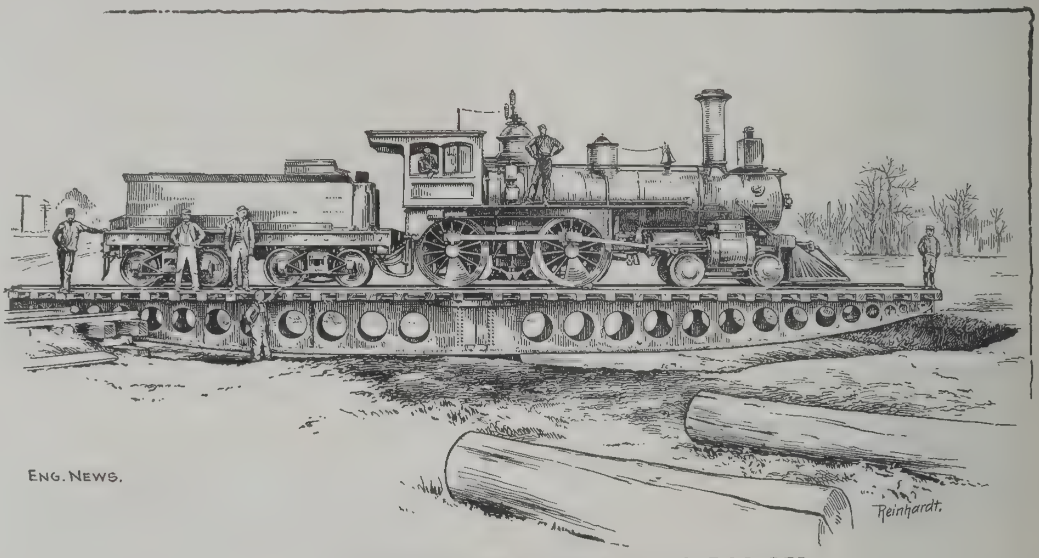

FIG. 7.—VIEW OF CAST-IRON GIRDER TURNTABLE LOADED.

Some of the factors which experience as well as theory have shown to be desirable are the following: (1) Necessarily the tables must be long enough to receive and balance the largest locomotive and tender in use; (2) it should turn easily under all conditions of weather, i. e., snow and ice, and freezing or thawing should not disturb its adjustment or make it turn hard; (3) its wearing bearings need to be of such material and construction as to withstand the load, and not to be disturbed or thrown out of position by shocks or the end thrusts of locomotives entering and leaving the tables; (4) it should swing true to center and preserve its adjustment horizontally and vertically; (5) it should be sufficiently rigid to swing under the heaviest loads with the outer ends of the table clear, and yet be so flexible that the shock of the locomotive will not dangerously strain or perhaps break it; (6) all these features must be obtained with a minimum of first cost and cost in repairs and operation.

How these various requirements come to be demanded will be seen if the operation of the table for the use intended is examined. It must tip to a firm end bearing to receive the locomotive, revert to a horizontal position with both ends clear, when the locomotive is fully balanced on the table, and remain so while the turning is in progress; tip to a bearing at the opposite end when the locomotive leaves the table; and finally revert to its original horizontal position. The variation in the character and intensity of the strains to which the table and its bearings are subjected during these manoeuvres is evident, but it will become definitely apparent if the strain diagram shown by Fig. 1 be examined. This diagram shows the calculable strains in a 65-ft. turntable with a locomotive and tender load of 170-tons, and was calculated by Prof. W. V. Brown, of De Pauw University. Three positions of the live load were assumed: (1) Locomotive balanced over center of table, end rollers not bearing; (2) locomotive moving over one arm of table, and load on other arm neglected; (3) one pair of drivers resting at end of table and remainder of load neglected. Only one side of the engine and table are considered. Of course this diagram does not cover the incalculable strains induced by thrusts and shocks, as these, as in bridge work, are allowed for by excess metal and strength and such construction, as experience has shown to be desirable.

Enough has now been stated to show that the proper design of the center bearing is a problem requiring considerable attention and to show how it has been solved by one designer the improved standard turntable made by the Greenleaf Turntable Co., of Greencastle, Ind., Mr. C. A. Greenleaf, proprietor, is illustrated. Fig. 2 is a general elevation of this table, and Figs. 3, 4 and 5 show details of various parts. Fig. 6 shows the details of a riveted girder table and will be referred to later, but Figs. 2 to 5 will be used to describe the construction and operation. It should be noted that the dimensions given are for a 100 tons capacity table.

The center post A is of cast gun metal 3 ft. 7 ins. high, 15 ins. diameter at the top, 19 ins. diameter at the base, and with flange base 2½ × 2½ ft. square and 4 ins. thick. Near the base is a roller path hardened and ground to a surface 19 ins. diameter and 9 ins. high. At the top is a spherical socket 12¼ ins. diameter, chilled and ground to a true surface and less than a hemispherical segment. In this socket rests a steel sphere, H, 12 ins. in diameter. Sitting over this the center post is a box consisting of a cap B, and a sleeve C, connected by bolts. Both cap and sleeve are cast gun metal. The cap is 26 ins. in diameter, 5 ins. average thickness, faced on the lower side, and having a spherical socket forming the upper bearing for the ball H. The sleeve is 26 × 26 ins. horizontally and 3 ft. 2 ins. vertically. On its outside are four 3½-in. vertical flanges to which the cross struts D are riveted, and at the bottom is an inside annular groove E, 24 ins. in diameter to receive the bearing balls 2 7-16 ins. in diameter. This groove is chilled and ground to exact size, and the bearing balls are of hardened and ground steel.

It will be noticed that the box is substantially prevented from lateral movement at the bottom by the close bearing of the ring of balls, E, and also that the spherical sockets for the ball H are of slightly greater diameter than the ball. The platform of the table is fastened to the cross struts D. Now when the platform tips at one end to receive the locomotive, the ball H rolls slightly toward that end, but as soon as the locomotive is once balanced on the table the ball seeks its original position, or in other words the table becomes horizontal. The tip of the table is of course controlled in amount by suitable end bearing. At the same time that the ball H is rolling to one side and back again the balls E undergo a slight vertical movement. Enough has now been said to show the theory of separation of the center bearing.

For 60-ft. turntables of 100 tons capacity the builders consider that girders of cast gun metal are preferable, but for tables of greater length or capacity cast gun metal is not so satisfactory. Assuming a table of the above capacity, four girder arms 44 ins. deep at the widest part and 30 ft. long are used. Both the bottom and top flanges narrow in width from the center toward the end of the girder, this taper being from 9½ ins. to 6 ins. for the top flange and from 8 ins. to 4½ ins. for the bottom flange. The thickness of the top flange is 2½ ins., and of the bottom flange 1¾ ins. The girder web is 1½ ins. thick at the large end and ⅞-in. thick at the small end, and is perforated with 12 holes of suitable size to relieve the shrinkage strains, but yet to have ample strength. The top flange of the girder is straight but the bottom flange has the line of a parabola.

Two girder arms coupled together at the center

NG TURNTABLE.

A. W. Greenleaf, M.E., Designing Engineer.

form a single girder for the table. These couplings are made by forged steel tie bars, fitting into suitable sockets cored out of the girder flanges. The atachment of the girders to the center box is shown by Figs. 3 and 4. Besides this lateral bracing there are cross braces about midway of each arm and at the end, and also a cast diagonal bracing. The lock, Fig. 5, consists simply of gun metal castings notched to receive the ends of the girders. The foundation masonry work is sufficiently shown by Fig. 1, and of course this is amenable to modification to suit conditions so long as it is maintained of sufficient solidity and strength.

It will be noticed that the intention of this design in all respects is to conform to the requirements laid down in a previous paragraph. It is entirely center bearing, there being no end rollers at all; by a thorough system of lateral bracing, the whole platform is designed to act as nearly as possible like a single beam; combined rigidity to carry load and flexibility to take up shock is provided by the coupled girders and by the center bearings and perfect and easy adjustment is sought through the ball bearings. In respect to the practical success of this construction toward the end sought we have the statement of the designer who expresses his faith from a long experience in building turntables.

It will be noted that the turntable described has cast-iron girders, but frequently riveted girders of wrought iron or steel are preferred. Fig. 6 illustrates one of these built a few years ago for the Lehigh Valley R. R. This is a 60-ft. table designed for the Lehigh heavy-grade engine, and calculated with the same assumed positions of the live load as is described above in connection with Fig. 1. The structural details are so clearly shown by the drawings that no further description is necessary. It should be noted, however, that the center bearing for which these girders were designed differs considerably from the one illustrated in Figs. 3 to 5, but, of course, this does not affect the girder design except at its connection with the center bearing.

Fig. 7 is a view of a cast girder turntable of the Greenleaf pattern, 66 ft. long and of 120 tons capacity. It will be noticed that the ends swing clear of any bearings when the table is loaded. For the matter from which this and the other illustrations have been prepared we are indebted to the Greenleaf Turntable Co., of Greencastle, Ind.

NATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.

The fourth annual meeting was held at the Tremont House, Chicago, Ill., September 1, 2 and 3, 1896. The meeting was called to order by President S. Uren (So. Pac. Ry.), of Sacramento, Cal., and the Mayor, Mr. George B. Swift, welcomed the delegates (who numbered 65) to the city. The Secretary, Mr. G. F. Hinkens (St. P. & D. Ry.), read his report, showing a membership of 150, 24 new members having joined at the present meeting. The Treasurer's report showed the following state of finances: Receipts, 1895-6, $464; expenses, $303; balance, $161. The President then read his address.

Report on Forges and Tuyeres.

The common square or round forge, of brick or iron, is good enough for all ordinary blacksmith work. The position of the tuyere, however, varies. Some smiths prefer the old style, solid or hollow for water, which is placed horizontally in the forge, and through which the blast is discharged to the center of the fire. This is not so effective in heating as when the blast enters the fire from the bottom of the forge, through a square iron blast box, which is provided with an opening in the top, fitted with a cast-iron grating having from one to four oblong holes, ⅜ × 2 ins., the grating with a single hole being large enough for very light work. These gratings can be removed and replaced by new ones, though if the blast box is kept clear of cinders and dirt they do not burn out. In the bottom of the blast box is a slide, which, when pulled out, allows all dirt and cinders to be removed. Such blast boxes or tuyeres are the only kind in use in the Southern Pacific shops at Sacramento.

Mr. Looker (Toledo & Ann Arbor) described a tuyere iron used in connection with the round forge. For a deep fire he had a box 12 ins. long, 9 ins. wide, and 5 ins. deep, with a double blast, and a long lid to cover it. In the center of one lid are two slots, ⅝ × 3 ins., and there is another lid with four slots. One lid could be taken off and another put on, according as it was desired to get a long or short heat.

Mr. Coleman (C. & N. W.): We use a common tuyere iron with a cast-iron box underneath. We have the side blast at our common forges, and underneath the tuyere iron we have the box, which is about 7 ins. square, and 6 or 7 ins. deep, with a slide in the bottom, and we find it very convenient in dumping the fire and saving coal. When we come to clean out we do not mix the loose coal with the dirt that drops through. I think we save at least one quarter in coal over the old plan of shovelling out the fires with the solid bottom. There is also a considerable saving in time in cleaning the fires; we clean them in from three to five minutes. I use a double blast also in the big fire, where we weld frames and do large work.

Mr. Robbins (Fitchburg R. R.): I have been using a tuyere having a cone-shaped top, with an oblong hole, about 2 × 1½ ins., with a ball that works into it, fitted with a lever. In the center of the ball is a hole about ¾-in. diameter. When it is desired to run a small fire, by bearing down on the lever, it throws the ball up, closes the large hole, and allows the blast to circulate through the small hole in the ball. At the bottom of the tuyere is a clapper, which we lift out, which allows all dirt and ashes that pass down through the tuyere into the ash box to be cleaned out very readily. The advantage of the cone-shaped top of the tuyere is that all slack and cinders run off below the outlet of the tuyere, which prevents all clogging.

Report on the Best Method of Manufacturing Axles.

To make a good wrought-iron axle we must have a good reverberatory furnace, clean gaseous coal, good scrap, steam hammer, suitable tools and the necessary help required to do the work. Use such scrap as old archbars, bridge plates, bridge rods, small car axles, etc. All scrap should be milled so that no foreign matter remains upon the iron. Cut the scrap into lengths of 18 ins., having piling boards cut from any rejected lumber. Also have a quantity of some iron that is nearest muck iron, such as splice bars, fish plates, etc., well milled and cut to lengths as above, and add about 30% of this muck iron to each pile you put up, well distributed. The slabs will not be so dry and there will be less danger of fire cracks, as the amount of flux will be greater. In piling your scrap use Beattie's system of piling.

The iron so piled and worked into slabs and then into axles will stand severe tests, as the fibers are entwined about each other in such a manner that when the axle is completed it seems almost impossible to break it, provided the iron has been properly heated. Some of our committee favor a two-slab axle, while others favor a three-slab axle, but this is a question that will have to be left with the railway companies that use them to determine what material will be best for a car axle; for the question of the iron axle and the best method of making it so as to give the best service is a matter of tests.

A great many of our leading railways have had made for their own use a muck bar axle under specifications of their own. This axle has proven to be very good and has given good service. The question may be asked: "Why do they want a muck bar axle?" The answer is that we cannot get wrought-iron scrap that is free from steel, as there is so much steel in use now by car manufacturers that it is impossible to get miscellaneous wrought scrap without there being steel scrap in it. You will have more or less soft pieces mixed through the scrap pile and it cannot be detected. So it will be worked and the result will be a weak place inside of the slab. The slabs will be piled together, the axle forged, and you still have the steel in the axle. If the piece of steel gets into a pile of wrought scrap, and the pile is worked into a slab, you will find if you break the slab that the iron has all been worked into one mass, or changed from a lot of small pieces into one piece, but you will find that piece of steel in about the same shape or condition as when it went into the pile. With such contingencies how can we build an iron axle that will stand the M. C. B. test, as was recommended by the committee at the last meeting of that association?

Mr. Mick: In taking scrap iron, old archbars, etc., and making slabs out of these, and putting them into the axle, they are too homogeneous to make a good axle, and he found that it was necessary to put something in there to assist this dry iron, and in the manner of piling it is intertwined in such manner that fire cracks were out of the question, as far as his experience had gone, and he had made a good many axles.

Mr. Williams (C., A. & C.): He would not test an axle in the middle, because that is the best part of it; anywhere from 10 to 18 ins. from the end is the place to test the axle; they always break in that place; he never saw an axle break in the middle from actual wear and tear; anything that breaks an axle in the middle generally breaks up the whole train.

Mr. Judy (B. & S. Car Co.): To say that axles do not break in the center is a mistake; he had seen five axles break inside of one week within 3 ins. of the center, supposed to be first-class axles, both iron and steel. The thing is to prepare an axle that will meet the specifications of the railway companies; they are the people who know whether the axle does the work or not; they discover this from tests and trials in service. Axles will break in the center and in the journal and back of the wheel seat; the companies have found out that the place to test them is in the middle or they would not do it.

Mr. Uren: The center is worked down to a blood red heat, and no iron retains its strength until it is worked to that heat. The end of the axle is finished at a white heat, and then placed in water for the purpose of cooling it. Consequently, the 5-in. part of the axle has not had the same working as the 4¼-in. part, and for that reason it is more crystalline, and my experience is that 25% more axles break at the wheel fit than in the center. Any iron finished at white heat is almost useless.

Mr. Mick: The difficulty arises from the fact that the workman does not have the fire bridge in the proper shape, and the heat is greater where the wheel fit is than it is where the center is, and it becomes fire cracked, and after the axle is in service it will break behind the wheel because the axle was injured in heating.

Mr. Burgess (C. & E. J.): It is almost invariably the journal that breaks. Car axles when running will get overheated and are cooled off with water, and that process goes on, and it is easy to see why the axle breaks at the journal.

Mr. Judy: There are some specifications that call for an axle to be made of muck bar. I know of one company which requires a piece of bar iron right in the middle between two scrap slabs. I do not think you can pile up old rails and work them over the hammer and expect a good job.

Mr. Norris: The greatest percentage of steel axles break in the periphery. It starts on the outside, and gradually breaks down until it comes within an inch of the center, and then it parts, and that occurs when the dead weight comes on the axle in the stopping or starting. There is one thing about steel and iron axles. The M. C. B. requirements say that an iron axle, 4⅝ ins. center, shall stand two blows at 15 ft. and three blows at 10 ft. The same axle in steel shall stand five blows without any fracture at 29 ft. If the M. C. B. do not know that steel is better than iron why do they put such specifications for them to fulfill?

Mr. Fitzgerald (C., M. & St. P.): The experience on our road has been that most of the axles break behind the wheel seat. The great objection to the steel axles which are on the road is that they break off quick, whereas the iron axles commence to crack, and the man who examines them has a chance to see the cracks in time to take the axles out, so as to avoid a wreck. I experimented a good deal with scrap last spring, and the result of my experiments was that the best scrap to make axles out of is old coupling links and some round iron to fill in with; it gave the best satisfaction.

Mr. Robbins: I claim an axle will break where vibration ceases and crystalization takes place, which is right back of the wheel fit, provided the wheel is forced up on to the shoulder. On the train on which I came to Chicago they had a hot journal, and when the train stopped the journal was red hot; and the trainmen used eight or ten pails of water to cool it off, and in running the 200 miles the journal was cooled off five times in that way. What condition is that journal in to-day?

Mr. Mould (N. Y., L. E. & W.): I think the day may come when we as blacksmiths may say that a steel axle is better than an iron axle, but I doubt if we are in a position to-day to say so. If a steel axle has been used and run its service what is there left in it for the railway company? With the iron axle we make almost everything on the locomotive. What will you do with the old steel axles?

Mr. Uren: We are manufacturing in the Sacramento shops 30 axles daily, and have been doing so for the last 25 years. We make these axles from ordinary scrap. As to getting steel into the axle, sometimes, undoubtedly, it will get in, but we avoid that as much as possible. The percentage of broken steel axles is far greater than that of iron axles on our road.

Mr. Norris: The company which I represent make more steel axles than any other in the United States. Some railways do not specify what the freight axles shall be made of, but only what the passenger axles shall be made of. One prominent road in the East says that it cannot afford to make any distinction. The only road in the country that can afford to make a distinction is a single track road, where trains are not passing each other continuously.

Report of the Best Methods of Constructing and Repairing Locomotive Frames.

In view of selecting the scrap for frame work, can it be said that we know the condition of this material, or what it contains, or how often it has been reworked? Very evidently in most cases it must be an unknown quality of material. In the selection of scrap much care should be exercised in selecting a good, clear iron free from corrosion to be sheared suitable for piling. Steel and other foreign material should be avoided. In preparing the piles for the heating furnace, muck bar iron should be at hand and mixed in among the scrap, this will increase the amount of slag, making the iron more fibrous. The doubled refined iron is still better than the raw muck bar. The good, sound judgment of a heater is of great importance, as the properties of the iron in the finished state can be rendered useless by the inability of a heater. Likewise with the hammerman; he must understand thoroughly the manipulating of the iron under the hammer to obtain first-class welding. The iron should be handled as quickly as possible, while in a welding state. The hammer should be heavy for shingling purposes, as in the blows alone rendered by the hammer depends the compactness and the welding of the iron; also the removing of any unavoidable foreign substance that may be located in among the iron. No weld should exist or be recommended in the construction of a new frame back. The frame limbs and braces should be forged at the hammer. When the different forgings have been completed at the hammer and the forging in question turned over to the blacksmith for final construction, too much skill cannot be displayed by the workman in welding the different parts together. The fires should be clean, it being most important that every condition necessary for welding should be in the highest state of perfection. This requires that the iron should be at the right welding heat to obtain the required results. A great deal depends, however, in the preparing for the weld. The frame back should be V-shaped at an angle of 45° or 50°, the limb should be split; the angle should be well open in order to secure the union at the apex of the angle, and provision be made for the necessary amount of stock required to make the weld. The welding should be executed under the steam hammer. In all railway shops of importance, repairing locomotive frames is a frequent occurrence, and to obtain the necessary results, skill and good judgment is required on the part of those supervising the work. Some foremen may be of the opinion that when part of a frame is broken it should be cut out and replaced by a new piece. That this method is economical and good practice is unquestioned, when the frame is not up to the standard dimension, as the case may call for, on account of having been repaired or welded previous, or some other defect. But when the frame is of full size. it is quite possible to replace it at an advantage with less expense and quite satisfactory. Very frequently we have a frame broken through the back, the frame being otherwise in good condition; it is quite practical to cut out of the frame a V-shaped section at the point of fracture, making provision for the amount of material it will require for welding. The parts should be firmly clamped together in view of holding them in the proper position. Weld in a piece that has been prepared for that purpose, the frame then turned over and the same operation of welding repeated, and, no doubt, if the proper care is exercised, the repairing of a fracture of this kind will meet with good results. In cases where frames are badly bent or kinked, it requires skill to straighten them in good shape. To do this, it is advisable to cut the brace, then the frame can be straightened to an advantage, and in rewelding the brace, care must be taken in keeping the frame straight.

Report on Furnaces and Fuel.

The soft coal sand bottom furnace has been discussed at a previous meeting, and also the coke furnace, most commonly used in railway shops. The usual forging furnaces are only used in large shops, and then mostly for axles, shingling or heavy forging. Small shops, as a rule, do not have hammer power enough to operate them economically, as it costs from $19 to $22 per day to operate such a furnace, and small shops cannot keep it going. Hence, to be economical, the coke furnace comes into more general use. This furnace may be improved in having an outer wall with 3 ins. space for the circulation of air with a few holes 3 or 4 ins. on the side to make it more comfortable to work at. Water jackets and other methods are used to serve this purpose, but the double wall is preferable. As this era of machine forging is advancing, we all meet the problem, how are we to keep the machine busy? Here is really where the output is gaged. The different locations in which we are placed has somewhat settled what fuel we will use in the great gas belt, in a coal region or oil region. For small furnaces, such as bolt forging or bending on car work, oil is the best fuel both as to economy and efficiency. Some use compressed air to atomize the oil; some only use fan blast of about 6 to 7 ounces per sq. in.; others use steam as an atomizer. The efficiency of oil furnaces is very much improved when the blast pipe is brought in contact with the flame after it has done its work in the furnace. By this means the blast may be heated quite hot, and in that order the oil may be conducted along the steam pipe of the steam hammer. By this method the oil also is heated and becomes very fluid. Various methods are also used for conducting the oil to the furnace. Some use a pressure of air to force the oil to the furnace; if this be done the pressure should not exceed the blast pressure, as the opening of the needle valve is so small when high pressure is used, it is liable to get clogged up. Gravity is in common use, the oil being pumped into a stand-pipe, it being always kept overflowing; 10 or 12 ft. high will generally be head enough. Oil is also a very suitable fuel for spring work. In a spring furnace some prefer to put the burner in the side, others on the end, but in either case there should be a space of about 6 or 8 ins. from the nozzle of the burner to a bevel brick bridge placed so that the oil and blast will strike. This will spray the oil, and then the course of the flame should not be obstructed by square corners, as it will be easily understood that striking squarely into a brick wall will stop its heating capacity. The flame should have a rolling motion, going to every nook inside the furnace and heating it evenly throughout. If the burner be placed on the end the same bevel bridge of brick is used and throws the oil to the roof of the furnace where it strikes a reverse bevel brick, throwing the flame down to the bottom of the furnace, thence along to the small stack 4½ ins. square, 24 ins. high, located about 8 ins. from the opening. A furnace of this class on spring work will run 20 to 24 hours on 50 gallons of oil, and can be kept at the proper heat very easily. Another very good spring furnace is used on spring work on the same principle as the sand bottom soft coal furnace, where soft coal is the fuel wished for. For flue work oil has also been in use in some places, but a small brick fire with feeders for the fuel at both sides is better. The mandril on which the flue is welded enters the furnace so that we do not require to lift the flue out of the fire but only push it through. By this method we have a sleeve or thimble to fit the various lengths and upset against this and the die of the machine, then raising the upper die allows the flue and sleeve to pass to the proper position to be welded. In some places they mix hard coal with coke, but hard anthracite coal is best for this purpose. A certain rolling mill is using gas made from an inferior coal, and this works very well. They have a producer built about 20 or 30 ft. from the furnace into which they put this poor class of coal. They force the fire by steam, driving the gas from this retort or producer to the furnace, which is a large one, having four doors. They run 60 blooms to a heat and 7 heats per day, making some 25 tons of finished iron. They get the fuel for the cost of freight and by this method they can make good iron from fuel that could not be otherwise used.

Mr. Judy: I have seen the oil furnaces working as fine as possible. They say they are doing double the work, and are working the oil with compressed air. I have seen them work their bolt machines in Cleveland, where the oil is carried to the furnace by gravity; also at Altoona. As to the coal furnace, it is nothing more than a reverberatory furnace and works well; but there is more loss of time with coal than with oil. The beauty of the oil furnace is that they can start the furnace and in 20 minutes get a hot furnace; whereas coal furnaces have to be kept going all night. Gas works well after you get the furnace hot, but it takes too much time to get the furnace hot.

Mr. Boyle (C., B. & Q.): We have been using oil in our furnaces for the last six years; furnaces for heating bolts, and also for bending iron and all shapes for car work. We consider them to be much cheaper than either coal or coke. We have an oil furnace which costs from $15 to $20, with which we can turn out four to five thousand ¾-in. bolts in ten hours, at a cost of about two cts. per hundred for fuel. For bending arch bars and all other kinds of car work, we use a furnace that was originally built for soft coal, Indiana block, that used to cost us in the neighborhood of $8 or $10 a day. With the oil we can bend five to six hundred archbars for about $2 cost of fuel. Our oil burners are of our own construction, and cost very little more than the cast iron, with the exception of the patternmaker's time to make the pattern, which will do for all the furnaces. The furnace which we use for bolt making is constructed with four legs, about 25 ins. high, the proper height for a man to stand at, with a common frog plate, 22 × 54 ins., placed on top of the four legs for a foundation body. We have two burners, one in each end of the furnace. The furnace is built on this frog plate. The front of the furnace has one brick standing on end about 9 ins. high. The end of the furnace where the burners come in has one brick laid flatwise, 4 ins. The back of the furnace has one brick laid endwise, and then these bricks are crossed and recrossed up to about 22 or 23 ins., with a top of brick laid edgewise, and compressed with a band of iron 3 × ¾ in. It is a very cheap furnace and does not cost much to operate.

Report on Machine Forging.

It used to be the rule to forge a piece of work at the hammer and then take it to the blacksmith, who would trim and finish it, allowing about ⅛-in. for the machine to take off. For work that has to be finished in a machine shop, this is an expensive way of doing work, for the very part that the smith took so much pains to make smooth and nice is cut off by the machinist, and the smith's nice work is thrown in the bins as scrap from the lathe and planes cuttings. All this should, and must be done away with if we expect to keep pace with the times and keep our shops up to the standard.

As to locomotive and car forgings, money can be saved by the use of machine tools such as steam hammers, and with plenty of suitable dies much of the work can be completed at the hammer without any blacksmith's labor. Such work will include main rods, parallel rods, T-ends for frame brace, pedestal caps, cross-head guides, cross-head guide yokes, frame clamp and pads, cross frame braces, back and front frame braces, solid links, crow feet, many boiler brace ends, link hangers, valve ends, etc. The majority of these must not go to a blacksmith, except when a weld has to be made. Large sized bolt machines can be used for much light locomotive forgings. Hydraulic forge machines and drop hammers are used in many shops, doing a great amount of work at very low cost.

In car forgings, bulldosers, large bolt forging machines, together with steam and power hammer are indispensable in producing good, cheap work. In fact, we do not know where the work with dies will stop in a car or locomotive shop, for every day develops something new.

At Thursday morning's session the first business was the report of the Committee on "Tool Steel, Tool Making and Dressing." The report was chiefly a discussion of the proper method of tempering steel for tools. Concerning quality of steel it says:

We are now getting as good steel as we ever did, but it is called upon to do from 25 to 40% more work in ten hours than it did formerly. The new machines are now built larger and stronger, and run with increased speed, from which fact the tool must cut off more metal.

Mr. Uren presented a supplemental report, in which he favored one uniformly good quality of steel for all purposes. He said:

We use an enormous quantity of steel; we carry in stock from 40 to 50 tons. We are 2,500 miles away from any steel manufacturer, and it is impossible for us to get special steel for each special job; but if it is a good quality of steel it will answer for almost any purpose. There are cases where we know ahead what we are going to use steel for, such as special sizes of taps, dies and reamers, and we use special steel for those purposes. A good quality of steel should always be used, and it will, in my opinion, answer for almost any purpose. If you use good steel in your tools when they are worn out they will go into something else. We always work our cold steel into something else.

Mr. Uren's ideas were combated by Mr. Burgess, who said:

I would just as soon expect to get one grade of steel to answer all purposes as I would to get one blacksmith that was equally good at spring-making, tool-dressing, and, to carry the thing further, as a frame maker. We have not only one, but quite a number of steel makers in this country that can turn out as good a quality of steel as anywhere on the globe. The American manufacturers have reached a point, where if you will tell them the use for which the steel is intended, they will send you a steel which will do the work satisfactorily.

After an extended discussion on the report on "Tool Steel," in which many differences of opinion were shown, the report of the Committee on "Flue Welding," by Mr. H. G. Finn (West Shore Ry.) was then read, as follows:

On our road we have been butt flue-welding for the past year (since June, 1895). We have about 100 engines on the road with butt-welded flues, and have not had one give out or leak. It is my opinion that it is the best way to weld them. We cut the safe ends 6½ ins. long off No. 10 flues, and our flues are No. 12, cut square off. We put the safe end on the mandril, with the collar about 3 ins. from the end, and they are put in a small furnace. We use hard coke. We butt them together, and when they get hot enough to stick, give the mandril one sharp blow with a 4-lb. hammer. Then it is ready to weld. When the heat comes up give the mandril three good blows with the hammer and it is welded. Then take it out of the fire and swedge it to size. In this way you will make a perfect weld every time, and the flue is full thickness at the weld. In this way we can weld 250 flues in ten hours.

Some discussion followed the report, two of the members believing that butt welding was not as good as scarf welding. We quote the remarks of two members:

Mr. Judy: It has been proven that a butt weld with a tensile strain is all right, but when it comes to vibration it is a question whether it will stand. I believe the butt weld will be a failure, but hope not.

Mr. McLelland: In Colorado, during the past year, we have welded 26,000 flues, which cost us, from the time they were taken out of the boiler until they were put back, an average of 10 cts. each. I went to the shops at Horton, Kansas, last Friday. The flues had been prepared for welding. They were scarfed and put together. The furnace was there, and machine alongside of it. At 8:24 a. m. the man who was welding laid a welded flue on the floor, and at 9:24 there were 110 more welded flues lying alongside of it. The cost of welding flues this month in Horton will be 6.02 cts. I am not certain that it is what would be called first-class welding, but it answers the purpose. There is no doubt that you can weld 100 flues in an hour and not overwork yourself. The fire can be cleaned out in about 20 minutes, and is ready for another 100.

On Thursday afternoon the report of the committee on "The Best Method of Handling and Disciplining a Shop," H. A. Folk (Pennsylvania R. R.), chairman, was read. He said:

In the first place, you do not want too many rules; secondly, do not make any rules that you cannot consistently carry out or that might place you at a disadvantage under some circumstances. Always remember that men have hearts and feelings, that they are just as sensitive to unkind remarks as you are; hence, it is very necessary that when any of your men are taken to task for neglect of duty, that you keep your temper. There is nothing cuts so deeply into the human heart as when a man is corrected for a fault in a kind yet firm manner, unless the man is so hardened that he cannot realize his offense, in which case you have no room in your shop for him. Do not argue any question of discipline with your men; do not become too familiar with your men; make them all your friends, but do not joke with them; many are too apt to presume on your friendship and you also invite too much familiarity. The employee should be made to feel his responsibility; that he is part and parcel of the shop and to a certain extent responsible for its success. Foremen should grade their men and pay them according to grade. If a difference is made and it is properly understood it will be an inducement to the inferior workman to try to improve. In our shop all the work is done on the contract or piecework system. We have an inspector who approves or disapproves of the work and accepts only such as is manufactured properly. The balance is thrown back on the workman's hands and is his loss. As a consequence there is very little iron spoiled, as men do not care to work without compensation. A firm, able, judicious administration will be felt by all of your subordinates, and a foreman who embodies these three principles is a good executive officer.

The next report was that of the committee on "Case Hardening," John Buckley (Illinois Central Ry.), chairman. The report is as follows:

We place the work to be case hardened in a cast or wrought iron box, putting about 2 ins. of granulated raw bone in the bottom of the box, and placing the pieces to be hardened about 2 ins. apart, filling in the vacancies between the pieces until you have covered them with 2 ins. of bone. Then place in the box another layer of work to be hardened, and continue in this manner until the box is full, being careful to have the work on the top of the box covered with not less than 2 ins. of bone; then place a cover on the box, and lute with yellow mud or fire clay. Then put the box in a furnace or open fire (furnace preferred) and subject the box to a strong heat from 8 to 16 hours according to the size of the box, and the bulk of iron to be hardened. Then remove the pieces one by one, clean them with a broom, and chill in clear cold water, and then there will be a uniform coat of steel on the entire surface from 1-16 to ⅛-in., as may be required according to the time it is left in the fire; the longer it is left in the fire the deeper will be the coating of steel.

To case harden large pieces of iron, such as guides and crank pins, it is not necessary to harden the ends of the guides nor the wheel seat end of crank pins. When hardening guides, we cover the ends with a small piece of sheet iron, ⅛-in. thick, then fill the ends of the box with sand. The sheet iron will absorb the liquid substance produced by the bone. When the guides have been chilled the ends will be soft. To harden crank pins we place two pins in a box, the wheel seat end of the pins to the end of the box, cover the wheel seat collar of pin with yellow mud, and fill the ends of box with sand, the center with bone. If the pins are large it will require 18 to 20 hours to give them a good coat of steel. After the pins have been chilled we frequently find them sprung and the surface fractured from the effects of being chilled in cold water. We have had good results from pins that after being removed from the box were cooled off in cold blast; the surface in this case will not be hard, but will have a fine coat of soft steel. By this treatment you will not lose any pins, which is frequently the case when they are chilled in cold water Thos. Sheehan, of Erie, Pa., patented a process for case hardening in 1870. We used it for many years and found it a good process when properly prepared. The ingredients are: Salt, sal. soda, charcoal, black oxide of manganese, black rosin and limestone. We have also used Houghton's hydrocarbonated bone black, and found it a first-class article.

The meeting passed a resolution of thanks to the officers, superintendents, superintendents of motive power, master mechanics and master car builders of the various railroads for their assistance in bringing the master blacksmiths together; to the Master Car Builder and Master Mechanics' Associations for their complimentary action with reference to the Association, and to all others who had assisted in making the meeting a success.

The following officers were elected for the ensuing year: President, R. A. Mould, of the Erie R. R.; Secretary and Treasurer, Geo. F. Hinkens, of the St. Paul & Duluth R.R. Chicago was selected for the next place of meeting, and the meeting then adjourned until the first Tuesday in September, 1897.

COMPRESSED AIR FOR POWER is being employed by E. D. Smith & Co., who are driving a two-mile tunnel for the Metropolitan Water-Works, of Boston, Mass. The tunnel is 11½ × 13½ ft., with four shafts and a portal. No. 1 shaft is 40 ft. deep; No. 2 shaft, 118 ft.; No. 3 shaft, 111 ft.; No. 4 shaft, 58 ft. deep. The entire work (including drilling, pumping and hoisting,) is being done by compressed air. The air is furnished from a plant placed betwen the portal and shaft No. 4. Air is carried about half the distance through an 8-in. pipe, then reduced to 6 ins., and afterwards to 4 ins. The air is furnished by two duplex Corliss engine air compressors, with steam and air cylinders 20 × 36 ins., built by the Rand Drill Co., which also furnished 24 slugger drills for the work. The plant has been fitted with a view to doing rapid and economical work on the tunnel. E. D. Smith & Co. have also made good progress on the work at Niagara Falls, where they are sinking a wheel pit 280 ft. long, 185 ft. deep, 20 ft. wide, for the Niagara Falls Power Co., the drilling, channelling and pumping for which are done with compressed air furnished by a Rand duplex Corliss engine air compressor, with cylinders 20 × 30 ins.

◆

ELECTRIC TRACTION is to supersede cable traction on the Wylie Ave. line of the Consolidated Traction Co. at Pittsburg, Pa. The cable was stopped at midnight on Aug. 26, and then withdrawn from the conduit. The engines and driving plant will be taken out. The conduit and track construction will be torn up, new tracks laid and the street repaved. All this work will be done by Booth & Flynn, the contractors.

◆

THE AMMONIA MOTOR CAR of the Standard Fireless Engine Co. was given a trial recently on the tracks of the East Louisiana Ry. Co., at New Orleans, La. The company desires to have its motor put in service on one of the street railways of the city.

◆

THE STREET RAILWAYS OF THE UNITED STATES, says the last edition of Poor's "Manuel," aggregate 15,956 miles in length, as compared with 13,176 miles last year; in five years the gain in mileage has been 6,294 miles. These lines possess an equipment, so far as the unsatisfactory statistical returns will show, of 28,154 passenger cars, 20,777 motor cars, 206 dummies and 28,621 horses. Since 1891 the number of horses in street railway service has declined 162,000, or about 80%. Out of the above mileage lines aggregating 531 miles failed to make complete returns of capitalization, etc. The 15,425.42 miles reporting show a capitalization of $828,547,285 in stock, and $525,949,928 in bonds; an average of $87,809 per mile in stock and bonds as compared with an average of $60,188 per mile for steam railways.

◆

A GASOLINE STREET CAR has been built at the shops of the Anacostia Ry. Co., Anacostia, D. C., being fitted with a motor invented by Mr. T. C. Pole, of Washington, D. C. The car has two sets of gearing, one for a speed of six miles and the other for twelve miles per hour. The gas engine is of 25 HP. and drives two heavy flywheels, the engine and flywheels running constantly at a uniform speed independent of the speed of the car. The car weighs about six tons and seats 25 persons.

THE CHIGNECTO SHIP RAILWAY ENTERPRISE is being revived in an attempt to have the Dominion subsidy renewed as a preliminary to raising more funds. This subsidy amounts to $170,602 annually for 20 years; but as the terms imposed upon the company were not complied with, it has been withdrawn by the Dominion Parliament. About $3,000,000 has already been expended upon the ship railway.

◆

THE FIRST RAILWAY IN COREA to connect the port of Chemulpo with the capital town of Seoul, 25 miles distant, is to be built by an American, Mr. James R. Morse. Mr. Morse was one of the first foreigners to enter Corea when it was opened to foreign trade in 1882 and holds other concessions, for mining, electric lighting, etc. The route of the railway has been surveyed by Mr. J. H. Dye, also an American, and the estimated cost of the road is $1,500,000 in gold. Seoul is only 100 ft. above sea level and the chief engineering work upon the line is a bridge, 1,600 ft. long, across the Han River. Under the terms of the concession the work must be commenced before March 29, 1897, and it must be finished within two years thereafter. The concession is for 15 years after opening, and it can then be purchased by the Corean government, or the concession extended for further periods of ten years. A French company has obtained a similar concession for a railway from Seoul north to Wi Ju, on the Chinese frentier.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week was caused by the collapse of a wooden bridge span in a trestle carrying the Arcata & Mad River R. R., over Mad River, near Eureka, Cal., Sept. 13. The train was running at very slow speed, as was the custom in crossing the trestle. It was an accommodation train, consisting of an engine, box car and two day cars, all of which went down. Of 20 persons on the train, 4 were killed and 12 injured, some being fatally injured. It is said that the bridge had one pier in the river.

◆

AN OIL TANK CAR exploded at Wellington, Ill., Sept. 10, setting fire to adjacent cars; 25 cars and a grain elevator were burned.

◆

A POWDER EXPLOSION occurred Sept. 11 at the mills of the Ohio Powder Co., near Youngstown, O., causing the death of two men.

◆

THE SHAFT OF THE STEAMER "City of Worcester" broke Sept. 10 while the vessel was on its way down Long Island Sound. from New London to New York, and the steamer had to be towed into port.

◆

A SMALL WATER TANK BURST at Washington Heights, one of the sections annexed to Chicago a few years ago. The tank formed a part of the water system owned by the former town of Washington Heights. It had a capacity of 60,000 gallons, was elevated, and apparently was of wood, as press reports state that "several iron bands burst."

◆

A SURVEY OF TWO RESERVOIR SITES, one in Wyoming and the other in Colorado, was provided for by the last Congress. The examination of these sites has been placed in charge of Capt. Hiram Chittenden, U. S. Engineer, St. Louis, Mo. Capt. Chittenden was to confer on this subject, on Sept. 10, with Mr. Elwood Mead, M. Am. Soc. C. E., State Engineer of Wyoming. The purpose of the proposed reservoirs would be to store flood waters and thus relieve the lower Mississippi from the danger of floods in times of high water and improve its navigation at low water.

◆

A SUIT TO RECOVER DAMAGES for death alleged to have been caused by decomposing garbage has been instituted against the city of New Albany, Ind., by the widow of the deceased. Damages to the amount of $20,000 are claimed for the death of the man and the subsequent illness of the plaintiff and her three children. A few days before the filing of this suit another one was filed by a different person to recover $5,000 damages for depreciation of property. The garbage in question is reported to have been dumped on a vacant lot.

◆

THE BARKER DRIVE-WELL SYSTEM, recently patented by Delbert L. Barker, says the Providence "Journal," is intended to develop water from pipe-wells driven into fine sand. The plan includes the sinking of an open pipe, larger at the bottom and armed with teeth, by using a jet of water under pressure. When a water-bearing sand-stratum is reached, the sinking is stopped, but the hydraulic washing goes on until a cavity is formed at the foot of the pipe. Into this cavity gravel or other coarse filtering material is introduced; and as the jet action can be continued to enlarge the opening by washing the fine sand up the pipe, an artificial filter-bed of considerable size can gradually be formed. It is claimed that more water can thus be obtained than by the ordinary driven well.

A BASCULE BRIDGE has been decided upon by the Board of Aldermen of Brooklyn and the Queens County Board of Supervisors as the type of structure to span Newtown Creek, at Vernon Ave., Brooklyn, N. Y. Various plans for bascule, lift and swing bridges had been submitted in answer to the advertisements in the columns of Engineering News, but no particular plan was adopted.

◆

THE EXTENSIVE FREIGHT TERMINALS of the Illinois Central R. R. at New Orleans, La., are nearly completed. The terminals occupy a space of 14 blocks at the head of Louisiana Ave., and are built largely on ground made by filling in. The plant includes a wharf 1,600 ft. long and 100 ft. wide, six miles of tracks, cotton storage sheds of 100,000 bales capacity, freight sheds, and a grain elevator of 1,000,000 bushels capacity. The elevator is 83½ × 300 ft., and 165 ft. high, supported on 3,000 piles 45 ft. long, carrying brick piers on which rests the main framing of the building. It has two parallel tracks with steam unloaders, handling 250 to 300 cars per day, one track having seven and the other four unloading legs, from which the grain is delivered to the 180 bins. Mr. L. L. Dagron is the Resident Engineer for the railway company, and James Stewart & Co. are the contractors for the elevator.

◆

A RUSSIAN-AMERICAN MINING AND METALLURGICAL Company, says the Philadelphia "Record," has been organized in Russia by Mr. Edmund D. Smith, vice-president of the Russian-American Manufacturing Company. This new company is to be conducted largely with American capital and entirely under American management. It is called the Nicopal-Mariopal Mining and Metallurgical Company, with a paid-up capital of $2,275,000, gold, and proposes to secure control of valuable manganese mines at Nicopal, in South Russia. These mines are now under American management, and the ore is to be taken to Mariopal, on the Sea of Azov, where a large steel plant will be erected under the charge of H. S. Loud, formerly of the Illinois Steel Company. The company has already secured the contract for supplying 144 miles of oil-pipe, amounting to about 10,000 tons, in the Caucasus; and to make the delivery in time the company has purchased the entire pipe-plant of Morris, Tasker & Co., with the exception of engines and boilers. This plant is now being shipped to Russia and the pipe is all to be delivered next year. The Russian-American locomotive works, at Nijni Novgorod, is to be opened as a department of the Sormovo Iron & Steel Works, at that place. The plant to be used has been designed by Walter F. Dixon, of Paterson, N. J., and Julian Kennedy, of Pittsburgh, Pa.

◆

TRADE WITH COSTA RICA is to be fostered by the establishment of a consulate in Philadelphia, and Mr. Gustavo Niederlein, Consul for Costa Rica, 233 South Fourth St., Philadelphia, Pa., notifies us that he will be glad to receive two sets of catalogues from manufacturers, together with particulars of terms of credit and discount, freight, etc. He will also be pleased to answer inquiries as to the character of goods desired, etc. Some notes on the Costa Rica Ry. will be found in our issue of July 9.

◆

A TWIN-SCREW ELECTRIC LAUNCH has been built at Nyack for John Jacob Astor. The boat is built of mahogany, and is 70 ft. long by 8½ ft. beam, and is 4 ft. draft. Two electric motors of 25 HP. each are fed by a battery of 480 cells. She was designed by Mr. Mosher.

◆

THE PIG-IRON INDUSTRY, says the "Iron Age," is adjusting itself to the late change in conditions, and since May 1 there has been a decline in production from 189,400 tons per week to 130,500 tons on Sept. 1. On Jan. 1, 1896, 241 furnaces were making 207,481 gross tons per week; and on Nov. 1, 1895, the maximum was reached with 217,306 tons per week. On Sept. 1, 1896, only 145 furnaces were in blast.

◆

THE TRANSMUTATION OF SILVER INTO GOLD by a chemical or metallurgical process is claimed to have been accomplished by Dr. Stephen H. Emmens, the inventor of the explosive, "Emmensite." The "Engineering and Mining Journal" of Sept. 5 contains a letter from Dr. Emmens, in which he reiterates his claim, but gives no details as to his methods. The "Journal" thereupon says, editorially: "So far as our knowledge goes there is nothing yet known that gives any firm ground for a belief in the transmutation of the elements; in fact, the tendency of scientific investigation seems to lead to the opposite conclusion. Neither is there anything in Dr. Emmens's statements that would convince any careful investigator that he has succeeded in converting silver into gold."

◆

THE NATIONAL ASSOCIATION OF STATIONARY Engineers is meeting in Cleveland, O., this week, with over 400 members in attendance. The association has over 10,000 members. Its objects are the scientific education of engineers and promoting the enactment of engineers' license laws in order to prevent destruction of life and property in the generation and transmission of steam. It has nothing to do with the subjects of wages, strikes, etc.

HINGED CONCRETE BRIDGE ACROSS THE DANUBE.*

(With inset.)

This bridge, which was designed and built under the supervision of Mr. Max Leibbrand, engineer, connects the village of Inzigkofen with its railway station on the opposite side of the Danube River. The traffic being very small, the appropriation had been put at the lowest possible limit, and it was necessary to observe the greatest economy in deciding upon the kind of structure and the materials to be used and in designing the structure. The condition of the river and river bed was not suitable for the use of intermediate piers, but the presence of solid rock on the right bank of the river and a hard gravel on the left favored the adoption of an arch.

As there were no stone quarries in the vicinity, while a factory producing most excellent cement was located within a short distance, it was decided to build the arch of concrete. Comparative estimates showed this to be a cheaper construction than either a Monier arch, or one of iron alone, or of cement blocks. An important feature of the design is the placing of open cast-iron links or joints at the crown and at the abutments. The arch hinged in this manner is statically determinate, and may be rationally and economically computed; moreover, any danger through settlement, after the falsework has been removed, is eliminated, as are also any secondary strains due to changes in temperature or to variations in the vertical loading, to which the arch can freely accommodate itself.

VIEW OF HINGED CONCRETE ARCH OVER THE DANUBE RIVER NEAR INZIGKOFEN, GERMANY.

The following dimensions were adopted: Span, 43 meters (about 141 ft.) and a rise of 4.38 meters (about 14 ft. 4 ins.). There is one roadway, 2.5 meters (8 ft. 3 ins.) wide, and two sidewalks, each 0.65 meters (2 ft. 1½ ins.), aggregating 3.8 meters (12 ft. 6 ins.) as the width between railings. The width of the arch proper is 3.6 meters (11 ft. 9½ ins.) at the crown and increases to 4.6 meters (15 ft. 1 in.) at the abutments, thus affording an increased resistance to all lateral pressures, such as wind, high water and ice. The arch ring is 0.7 m. at the crown, 1.1 m. at the joint of rupture, and 0.78 m. at the abutments. The roadway is carried on 36 small posts standing upon the extrados of the arch, except in the middle portion where it is carried directly on the arch. As shown in the section each three of these pillars forms a bent, the two outer ones being curved at the bottom on account of the greater width of the arch ring; longitudinally the pillars are joined by arches. On top of the abutment are rollers to provide for expansion and contraction of the roadway structure. At the crown joint the wrought-iron handrail is connected to a cast-iron post in which it is free to move, and at this point the roadway is supported on trough plates.

Without entering into the details of calculation, it is of interest to note that the usual method of establishing the line of pressure by loading one-half of the arch ring was not followed in this case, but the arch was divided into sections, and the effect of concentrated loads at these sections was determined. Indeed, the hinged construction demands this method of calculation, as the problem is a determinate one, and the arch cannot be regarded as one elastic mass.

Construction was started in July, 1895, with blasting and excavation for the abutments, and the bridge was opened to traffic in November of the same year. All concrete used was mixed by hand, and the various proportions adopted for different parts of the bridge are indicated in the illustrations on our inset sheet. The bents of the lightly constructed falsework were carried on four piles each; resting on the cap-pieces of these piles were sand boxes and wedges, as shown. The planking under the arch projected sufficiently beyond the face to allow the sideboarding to be braced against it. The abutment links were supported on saddles bolted to the arch ring of the falsework. These saddles served the purpose of resisting the thrust of the arch before it had been closed and filled in at the abutments. The abutment plates were each provided with four lugs and bolts in order to hold them in position during the concreting. Before the falsework was removed the lugs were knocked off and the bolts drawn out, leaving the hinge free to turn on its axis. The crown hinge was supported on timbers directly over the arch planking.

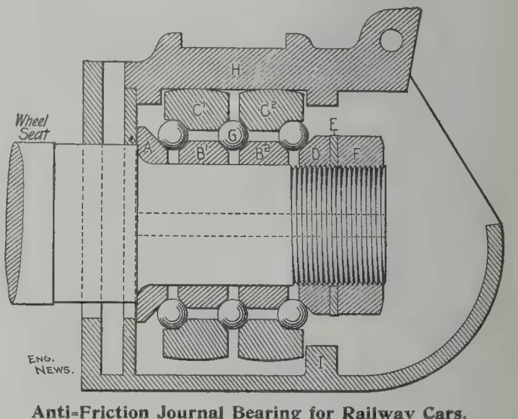
It is of the greatest importance that the axis of each set of links should be in true alinement, and perpendicular to the arch, as otherwise it would not be possible for the links to turn simultaneously, and secondary strains would arise, rendering the hinge construction useless. Behind the abutment links a space of 25 cm. (about 10 ins.) was left open to admit of the hinge following the settlement of the falsework; this space was not filled in until the arch was closed. The joints in the planking on the face of the arch were caulked with gypsum, and the interior surface covered with brown paper. The model of the arch ring, formed in gypsum, was then screwed on, and the whole coated with shellac. The planking below the arching was left rough, except for a space of 20 cm. next to the face, this strip being treated similarly to the front. Before concreting was commenced the falsework was loaded at the crown with the links and a number of sandbags, aggregating 40,000 kg. (about 88,200 lbs.). On Aug. 29 the concreting of the arch was started at the abutment links. The material was placed in sections boarded off perpendicular to the line of pressure, and from 1 to 1.3 m. long, and tamped in horizontal layers. The arch thus consists in reality of a number of concrete blocks of that length which, however, through the speedy progress of the work were most completely united. The concreting was advanced from both sides towards the joint of rupture; here a space of 1.2 m. was left open and work continued beyond this space towards the crown, the loading placed on the falsework being gradually removed. The open spaces at the abutments, and at the crown, were then closed, and finally those at the joints of rupture while concreting the spaces at the abutments. The end plates were supported on set screws, the strength of which was sufficient to withstand the slight thrust of the uncompleted arch, but not that of the arch when unsupported by the falsework. In this manner it was insured that the joints distributed the pressure over the whole surface, and not merely at the points of support.

The abutment piers were built next, and finally the pillars and arches supporting the roadway. On all visible parts of the bridge a layer of colored cement and sand from 10 to 15 cm. thick was put in simultaneously with the concrete and closely united to it.

Immediately after the roadway was completed and five weeks after closing the arch the falsework was removed. The settlements at the crown and at the abutments were closely observed from time to time by means of the apparatus shown in the illustration. The total settlement at the crown amounted to 32 mm., about 1¼ in., estimated at a temperature of 20°C. This was up to Feb. 10, 1896, the bridge in the meantime having been subjected to a test load. The roadway plates were covered with asphalted felt, ¼-in. thick, upon which was a layer of sand 4 ins. thick, then gravel, 3 ins. thick, which was finally covered with a thin layer of sand. The roadway is drained in the center and the water carried down the first row of pillars from the abutment. The total amount of concrete in the bridge is 634 cu. m., or about 830 cu. yds. The amount of cast iron in the hinges is about 33,000 lbs., and the whole work was executed at the estimated amount of 22,310 M., about $5,310.

ANTI-FRICTION JOURNAL BEARING FOR RAILWAY CARS.

Among the various mechanical improvements in the design of railway rolling stock which the ever present inventor is suggesting for use, "improved" journal bearings are perhaps as seldom seen as any. Nevertheless, such devices are occasionally brought to our notice, and in the accompanying cut one of the latest ideas in this direction is illustrated. This bearing, according to the inventor's statement, is to be given a trial by a prominent western railway, and is also of interest as exemplifying the persistent attempt to extend the ball bearing to new uses, with which engineers have become familiar during the past two years. It may be noted that the trail of the bicycle can be seen in the design, the inventor having been engaged in the manufacture of wheels and having developed his journal from suggestions obtained in that work.



Anti-Friction Journal Bearing for Railway Cars.

The device illustrated consists of a hardened steel collar A keyed securely to axle; collars B¹ and B² movable longitudinally on axle, but made to rotate with axle by means of a feather or key, and collars C¹ and C², which are confined loosely within the oil box and separated from B¹ and B² by a series of rows of balls. The collar D is screwed on to the axle, and forms one of the bearing surfaces, and is the adjusting nut by which all looseness or play may be taken up. This collar is locked in position by means of a washer E, containing a feather, which prevents it from turning on the axle, and F a lock nut. A cotter will be

used to prevent this nut from coming clear off the axle in case it should accidentally work loose. The oil box is made in two pieces, which are held in position by the jaws of the pedestal. and may be readily removed by jacking up the car body ½-in. The box is tight, and, it is stated, wastes no oil, as there is barely enough used to allow the balls to pass through it at the lowest point in their revolution around the axle. Hardened steel balls of 1 in. diameter are used. The collars are also made of a high carbon steel, carefully tempered, and their bearing surfaces are turned at an angle of 45 to the axis of the axle. This is done to eliminate all sliding friction between balls and collars, as it brings the axis of the balls parallel to that of the axle around which they rotate. The inventor, Mr. W. M. Shumway, of Chicago, Ill., states that the cost of this bearing is but little more than that of the ordinary journal bearing.

NOTES OF A TRANSCONTINENTAL TRIP.

(Editorial Correspondence.)

II.

Union Pacific Ry.

This line deserves celebrity for its position as one of the two great railways chartered by Congress to extend the railway system of the country to the Pacific coast, the other line being the Central Pacific Ry. In 1862 the U. S. government passed an act granting to these railways subsidies of bonds and lands to aid in the construction of a railway and telegraph line from the Missouri River to the Pacific Ocean, and it is much to be regretted that in both cases the debt thus incurred has resulted in clouding the history of the railways by financial embarrassments and by continual contests between the companies and the government. The Union Pacific Ry. was given 12,800 acres of public land per mile of road, and a subsidy in government bonds at the rate of $16,000, $32,000 and $48,000 per mile, the total amount being $27,226, 512 for 1,033 miles. The time fixed for the completion of the road was July 1, 1876, but as a result of the vigorous prosecution of the work the line was opened on May 10, 1869, simultaneously with the completion of the Central Pacific Ry. The original main line extends from Omaha, Neb., through Cheyenne, Wyo., to Ogden, Utah, 1,034 miles, but numerous branches, feeders and additional lines were built until the entire system aggregated a very considerable mileage. Of late years, however, owing to the financial troubles, many of these lines have been turned over to other companies, the latest line thus lost being that of the Oregon Railway & Navigation Co., the main line of which forms a northwest connection from the Union Pacific Ry. to Portland, Ore. This has lately been put under the control of a reorganized company. In 1893 the system operated had an aggregate length of 8,564 miles (including 982 miles of water lines), while the present operated mileage is4,442 miles. Westof Ogden may be seen the partly completed grade of the line built by the Union Pacific Ry. before Ogden had been decided upon as the junction point with the Central Pacific Ry., and when each company was straining every nerve to build as much mileage as possible in order to increase its subsidy.

The line has a good track, its standard rail being a 70-lb. rail which closely resembles the Am. Soc. C. E. section of that weight, but having top corners of ⅜-in. instead of 5-16-in. radius. The rails are laid with square, suspended joints, spliced with 40-in. bars and six bolts, but Mr. Geo. H. Pegram, M. Am. Soc. C. E., the Chief Engineer, is not in favor of such long bars. Burnetised ties of mountain pine and hemlock were at one time extensively used, the company having a plant of its own at Laramie, Wyo. The treated ties, however, lasted only about two or three years longer than untreated ties (8 years for the former as against 6 years for the latter), while they cost 14 cts. more, in addition to which there was the cost of transporting the ties to the treating plant and then back to the distributing point. It has, therefore, been concluded that it is cheaper and more economical to use untreated ties, but protected by metal tie-plates, and these plates (of the Servis and Goldie type) are now very extensively used.

A new spring rail frog has been designed by Mr. Pegram for use on this road, the special object in view in the design being to provide ample strength and security without unduly increasing the weight, as an increase in weight not only increases the cost but is also very likely to interfere with the easy working of the movable parts. The frog possesses many good features and costs from $3 to $12 less than those submitted by manufacturers. This frog will be illustrated in a later issue. Rigid frogs have but a short life on this road, averaging only one year, while in some cases they are cut out in two months by the pounding of heavy freight trains,and the pounding of the wheels of heavy cars in express trains of 12 to 16 cars, running at 60 miles an hour. These trains are hauled by powerful engines of the eight-wheel and ten-wheel types, and a notable feature of the locomotive equipment on this road is the use of the diamond stack and short smokebox instead of the cylindrical stack and extension smokebox which have been almost universally adopted within the past few years. This is referred to more fully below, and further detailed particulars will be published separately in a later issue. A number of bridges have been recently renewed with heavier structures, and in many cases the work of erection has been carried out with exceptional rapidity. The company is now rebuilding the bridges across the Weiser River, 400 ft. long, and across the Payette River, 270 ft. long, and a bridge of 172 ft. span across the Bear River on the Oregon Short Line. These are new steel bridges on stone piers taking the place of old wooden bridges on pile piers.

In regard to the express trains on this railway, above mentioned, it may be noted that our foreign friends, while admitting that good track and high speeds do exist on some of our main eastern lines, are very apt to assume that our western railways have tracks largely composed of mere streaks of rust and that the speeds are about equal to those of a wagon train or a prairie schooner. It would probably surprise them very considerably to find trains on the UnionPacific Ry. (as on many other main western roads) with 12 to 16 cars, many of these being heavy sleeping cars, running easily and steadily hour after hour over an excellent track at a speed of 50 to 60 miles per hour. Yet this is a daily regular experience.

Locomotive Smokestacks and Smokeboxes.

On the railways of the eastern states the straight smokestack and extension smokebox are now almost universally adopted, and the diamond smokestack and short smokebox are practically obsolete and looked upon as representative of an antiquated practice, while the old balloon stack for wood-burning engines is almost forgotten,although both these latter forms of stack are in use to some extent on old engines and branch lines. It is therefore somewhat surprising to find on reaching the Union Pacific Ry. that the diamond stack and the short smokebox are the standard types and are found preferable to the straight stack and extension smokebox. The reason for this is partly in the character of the coal used and partly in the arrangement of the exhaust nozzles. The fuel is a light friable lignite, very apt to throw sparks, to check which a deflector and netting in the enlarged top of the stack is found much more effective than a netting in the smokebox, while the low nozzle used with the former gives better results than the high nozzle used with the latter. The form of smokestack has a wide and somewhat shallow top very different from the ordinary deep, enlarged top of the old diamond stacks. Lest it may be supposed that the Union Pacific Ry. uses old and antiquated engines with the old style of front end construction, it may be said here, that the road has a very fine equipment of modern engines, which have a fine appearance and do splendid work, as will appear from some further details which will be published separately from these notes. It might, perhaps, be thought that this particular detail of practice is due to local ideas and prejudices, rather than to actual conditions, but both forms of stacks and smokeboxes have been tried, with results as above noted. A few weeks later I found exactly the same conditions existing on the Western Division of the Canadian Pacific Ry., and sought an explanation from Mr. Cross, the Master Mechanic of this division, who is located at the Winnipeg shops. It seems that this road obtains lignite from Lethbridge, a semi-anthracite (really a bituminous) coal from Canmore, and anthracite from Anthracite, all these places being in the province of Alberta, on the eastern slope of the Rocky Mountains. The bituminous coal is used west of Canmore, and on the Western and Pacific divisions, and there the engines have straight stacks and extension smokeboxes.

The lignite is used east of Canmore, from Gleichen to Winnipeg. Most of the engines burning the Lethbridge coal, or lignite, have diamond stacks, though it is also burned on some engines having straight stacks. The engines with diamond stacks have stacks of the old style, with a deep enlarged top. These engines with diamond stacks have a low exhaust nozzle, set below the tubes, and any sparks are driven against the deflector cone in the stack (not against the netting) again and again and are churned up with the steam, until dead, while any live sparks which may finally escape through the netting are nearly dead and are not blown far away, so that even in dry weather there is little danger of their setting fire to grass, etc., beyond the plowed fireguard along the right of way. With a straight stack and netting in the smokebox extension a high nozzle is required, and being above the tubes and netting it creates a suction tending to draw the sparks through the netting, and any sparks which do get through are then blown high out of the stack like rockets. Reference has been made above to the balloon stacks of wood-burning engines, and the sight of a heavy express train on the Southern Pacific Ry. drawn by two powerful ten-wheel engines having huge balloon stacks and tenders piled high with wood, is particularly striking to eyes accustomed mainly to the engines of eastern railways. In another issue I expect to give further particulars, with illustrations, of western practice in regard to smokestacks and smokeboxes.

Omaha to Denver.

After a few hours spent in and around Omaha, I continued my journey westward, leaving at 3.30 p. m. (July 3), on the Pacific Express, which leaves Chicago (Chicago & Northwestern Ry.) at 10:30 p. m., for San Francisco, by way of Omaha, Neb.; Denver, Colo., and Ogden, Utah. This was a very heavy train, but hauled by one eight-wheel engine. In crossing Nebraska one notices the rich-looking country and the great number of trees planted in groups and rows on the roads and farms, these trees (mainly poplars) being evidently intended as wind breaks and snow protections. At Julesburg the train leaves the main line of the Union Pacific Ry. and turns south over the Union Pacific, Denver & Gulf Ry. to Denver, which city was reached at 8:10 a. m., July 4.

On this latter line, in the vicinity of La Salle, are shifting sands, extending for great distances, the sand gradually covering and killing all vegetation and trees. It also encroaches on the railway, and portable fences, like snow fences, are used to protect the line, especially in cuts, but these seem to be of only very temporary use, being soon surrounded and buried. The sand must be worse than snow, for it is continually giving trouble, while snow only occurs during a few months of the year. A mixture of snowdrift and sand-drift in a railway cut would be a very awkward thing to handle.

Mr. T. F. Dunaway, General Superintendent of the Union Pacific, Denver & Gulf Ry., states that they are troubled with sand drifting for a distance of about eleven miles, between mile posts 119 and 130, on the Julesburg line. This sand comes from a formation lying to the north of the line. High north winds blow the grass from exposed parts and drift the sand towards the track. It being a cattle range, the tramping of cattle to and from the river, for water, prevents vegetation from growing and keeps the sand stirred up so as to be easily moved by the wind. To prevent its covering the track, it is treated much in the same way as snow, by building snow fences to catch the sand. It is necessary to change the fences (which are 6 ft. high) once a year.

All along this part of the route, and from here on at intervals all the way to San Francisco and up to Portland, one sees the jack rabbits and the prairie dogs or gophers in abundance, and they furnish endless amusement, besides recalling to mind the pictures in the old railway guides. The gophers are pretty little furry animals, not unlike yellow squirrels, and in some places the entire landscape is dotted with the mounds of sand which mark the mouths of their burrows. They usually scurry away when the train approaches.but occasionally one will sit up on the far edge of the ditch or on one of the mounds,and watch the train attentively or chatter excitedly at it. These little fellows are amusing enough, but the jack rabbits are still more so, and it must be a particularly sour or grim passenger who is not moved to exhausting laughter by their performances. The rabbits are not unlike large hares, sandy-brown and white in color, but with abnormally large and sensitive ears (hence the name jackass or "jack" rabbit). One of these fellows will sit immovable near the fence while the train approaches, and just as it is opposite him he will throw up his ears in alarm, and go off through the sage brush like the wind, with a nervous hopping and leaping action that will send a car load of sedate passengers into hysterical and breathless laughter. One begins almost to believe in Mark Twain's statement about a jack rabbit he saw from a train and which ran so fast that "long after he was out of sight we could hear him whiz."

Denver, Colo.

The general appearance of this city is very attractive, as it has fine buildings, wide streets which are well paved and well cleaned, and an abundance of parks and trees, all of which show to advantage in the bright clear atmosphere. It is situated at an elevation of 5,195 ft. above the sea level and has a population of about 150,000. The city has a remarkably clean and neat appearance, and there is a general air of substantialness and prosperity, although at the present time business is universally said to be dull. The best stores certainly excel those of New York in their general appearance and style, and in the artistic display of goods. The residence district has numerous large and handsome houses, and a specially noticeable feature is the beautiful condition of the lawns, due to an almost continual use of lawn sprinklers and a frequent use of lawn mowers. Among the handsome public buildings are the city hall, the Arapahoe County court house and the new capitol. The latter stands on the summit of a hill and is a very fine structure, built entirely of Colorado products and manufactures. It is not yet quite completed. Some of the public school buildings are quite imposing structures, and in one of them is the city free library. The union station is a handsome stone building, at the side of the tracks, but has no train shed and no covered platforms between the tracks. In fact, this condition is found so frequently at new station buildings (as at Denver, Pueblo and Ogden) that one is led to wonder whether the architects purposely omit these shelters for fear of spoiling the view of the buildings. This station was completed in 1894.

There is a very complete system of street railways, extending far out into the suburban districts, and most of the lines are operated by electricity, some of which have replaced cable lines, the conduit system remaining undisturbed. Combination cars, partly open and partly closed, are extensively used on the cable lines, and the grip cars of these lines have track brakes.

In walking through the residence streets one wonders at the beehive-shaped structure of brick plastered with cement which stands near the front fence of every front yard or garden. Ideas of a new system of individual garbage cremation begin to occur, until on inquiry it is learned that these are the receptacles for ashes, the ashes being thrown in at the open top and periodically shoveled out by an ash collector through what looks like a furnace door at the bottom. The position of Garbage Commissioner is held by a woman, Mrs. Mary Pickerell, who is said to be a very smart woman and a very alert garbage commissioner. Denver has other public offices held by women, including that of City Treasurer, and, as far as could be learned, the results of this have been highly satisfactory, the women being good managers, well informed as to their duties and are not apt to dabble in municipal "rings" or to go into politics to the neglect of their municipal duties. Women and bicycles go together a good deal in these days, and so it may be appropriate to note here the very extended use of the bicycle by women and men in this city. They ride to and from business; they go shopping and calling, and they go from place to place about the city in ordinary daily pursuits, where in New York they would either walk or take a car. This very general use of the bicycle is due largely to the finely paved streets, many of which have asphalt paving.

The organization of the municipal engineering department is somewhat peculiar. There is a city engineer, but he is in charge only of grades and street line surveys. There is, however, more work in this than might be supposed, as the city covers a considerable area, only a part of which has as yet had the street lines and grades officially laid out. Nevertheless the office may be abolished in two or three years, as by that time all work will have been done and all information recorded, unless the city again extends its limits by taking in more of the suburban districts. At present there are two field parties at work, each consisting of four men, with a light wagon to carry tools, monuments, stakes, etc. The sewer and paving work are under the supervision of the Board of Public Works, which has its own engineer.

Among business firms there was a general complaint of hard times and lack of orders. This was partly due, no doubt, to the present general and widespread depression of trade, accentuated by the period of depression to which this country is subjected every four years in consequence of the uncertainty arising from the presidential campaign. These adverse conditions are made even worse, by the mistaken (though sincere) advocacy of the free silver policy which is now causing so much trouble. Of course, people living in a silver state, where a boom in silver would mean a certain activity in mining, may be expected to be prejudiced in favor of this particular metal, but this is a very narrow way of looking at the financial question, and it must be said that the arguments heard for "free silver" were neither convincing nor based on good or broad grounds. Considering that the silver production amounts to only about 4% of the total mineral products of the country (ranking with lime and building stone) it is not easy to see why this mineral should be given more attention and assistance than the other 96% in value of mineral products.

Colorado Fuel & Iron Co.—This company has its general offices at Denver, and its steel works, rail mills, etc., at Pueblo, 120 miles south, while it also operates extensive mines of anthracite and bituminous coal. The pipe mill makes cast-iron pipe of 4 and 6 ins. diameter, but in view of the growth of water-works, increasing demand for water-works supplies, and the high cost of freight, it would seem to be a good time to put in a plant for the manufacture of larger sizes of mains. The rail mill has turned out large quantities of rails for western railways, the present average demand being for rails of 70 and 75 lbs. per yd. They are said to be higher in phosphorus than is usually allowed, but to have proved to be good wearing rails, which is owing partly to the comparatively slow methods of manufacture. Some of the older rails for the Denver & Rio Grande R. R. had 0.13% phosphorus, although not more than 0.09% is now allowed. The company's Bessemer steel works were closed down about the middle of August, throwing some 400 men out of employment, and the following statement was issued by the president, Mr. J. D. Osgood, in regard to this action:

> All rail orders are filled, and the present unsettled business and financial condition of the country prevents the railways from buying rails for renewals, and all new enterprises are held in abeyance. All the other departments of the company's works at Bessemer are in operation, and will be continued so long as we can find a market for the products. Whenever new rail orders can be secured work will be renewed at the iron mines and blast furnaces. This action was taken without consultation with or suggestion from the directors or stockholders.

The American Water-Works Association is to hold its next convention at Denver, in 1897, and will certainly have very much of interest to examine in the extensive water supply system of that city, as will be seen by some notes made during a partial inspection of the works in company with Mr. Charles A. Allen, Chief Engineer of the Denver Union Water Co. These notes are too lengthy to be inserted here, but will be given separately in a later issue. In about two years the city will be supplied entirely by a gravity system, except for two high-service pumping systems on high summits. The system includes many miles of wooden stave pipe (with cement lined tunnels at summits), a large storage reservoir or lake, a sand filtration plant, etc., while the company also owns and operates ranches purchased with their water rights. There is a Venturi meter on the pipe line, with automatic recording apparatus, and among the proposed works is a large masonry dam in a mountain canyon to form an extensive reservoir.

Colorado Springs and Manitou.

At 7 p. m. on July 7, I left Denver by the Denver & Rio Grande R. R. for Colorado Springs, taking the New Mexico express (narrow gage), which runs through to Santa Fe, N. M. About ten miles from Denver is Fort Logan, a large U. S. military post which is just now a special center of attraction from the fact that Custer's cavalry is now stationed there. For some 30 miles the line runs along the plain, close to the slopes of the mountains, and then begins to ascend the Divide, reaching a summit at Palmer Lake, 7,237 ft. above the sea, and then descending to Colorado Springs, 75 miles from Denver, which was reached at 9.51 p. m.

This city is a most delightful place for rest and recreation, being 5,995 ft. above sea level, and having a wonderfully clear, invigorating and bracing atmosphere. The population is about 17,000. The streets are 100 ft. wide, and the avenues 160 ft. wide, and, with the exception of the few main business blocks, are almost all lined with good-sized trees, while Nevada Ave., the main street, has two rows on each side and two in the middle. Rushing and splashing streams of cold mountain water run through the irrigation ditches on each side of the street, there being usually a turfed strip between the sidewalk and the ditch. These ditches are mainly lined with plank, and have laterals extending to the gardens of the houses, plank gates being provided so that the water may be shut out of the laterals except for the length of time during which the owner is authorized to take water. Where new lawns have been made, the water is sometimes allowed to flood the entire lawn, to a depth of 1 or 2 ins., in order to thoroughly soak the underlying earth. Besides this system of garden irrigation, however, there is an almost universal and continuous use of lawn sprinklers, with the result that the houses stand amid beautiful velvety lawns and have their grounds rich with flowers and plants. In marked contrast to this richness are the occasional unoccupied and unimproved lots, on which the grass is a pale yellow and grey, burnt and scorched from the heat of the sun and the lack of water. This, on a small scale, is illustrative of the great changes which have been gradually wrought by irrigation, transforming what was practically a desert into a fertile and productive land. The great heat of a summer day is not oppressive, owing to the dryness of the atmosphere, but nevertheless on such a day the sight of the profusion of green and foliage and the sound of the rushing irrigation streams are most refreshing. The roads are well macadamized and kept in good condition for driving. The business blocks are substantial and of good appearance, and here, as at Denver, one is struck by the handsome appearance of the stores and the artistic way in which the goods are displayed. The water supply is obtained from mountain lakes on the slopes of Pike's Peak, and extensive works (including a long pipe line and a tunnel 6,000 ft. long, driven by electric drills) are now in progress for supplying water for domestic and power purposes, but as the present system and the new works were described and illustrated fully in Engineering News of Aug. 27, no further mention thereof need be made here. The work is under the supervision of Mr. H. I. Reid, City Engineer. The city is close under the mountains, the most conspicuous peak, from certain points of view, being the celebrated Pike's Peak.

The city is rather inaptly named, since it has no springs, the springs being at Manitou, five miles distant. This is on a branch line of the Denver & Rio Grande R. R., but there is also an electric line, which, with its frequent service of cars takes the bulk of the traffic. The Colorado Midland Ry. has both Colorado Springs and Manitou on its main line. The early train on the Manitou branch is an accommodation train, and has the engine placed between the passenger cars and the freight cars. At the intermediate stations it pushes the freight cars onto a sidetrack, leaves those for the station, and then after backing out goes on up the main track to couple up to the other cars which are to be taken on, these cars having been switched onto the main track in front of the train. From the cars may be seen a portion of the "Garden of the Gods," with the curious isolated blocks, columns and masses of bright red rock, which are styled statues, pillars, cathedrals, etc.

Manitou, with a population of 1,800, is a pleasure and health resort situated on the slope of the mountains, 6,324 ft. above sea level, and is a very pretty place, populated mainly by tourists and invalids. Numerous springs of mineral water (soda and iron of various compositions) occur here, and at the largest there are pavilions where persons can sit and listen to the bands or stroll around and purchase photographs and various mementos of their visit. The most attractive spring to persons in good health (who taste nauseous waters merely in order to say they have tasted them) is the great Manitou soda spring, where soda water far superior to any of the manufactured varieties, bubbles up in a large basin or shallow well, and is distributed in glasses by the genius of the spring, in the form of a small boy clothed in everyday costume with the addition of a pair of high rubber boots. On the street may be seen men, women and children carrying bottles to be filled at the overflows from the springs. A large proportion of these bottles were made to contain various alcoholic liquids, and are not elsewhere carried openly in the streets. At Manitou, however, these suspicious-looking bottles are carried about in broad daylight with no attempt at concealment, the owners being conscious of the innocence of the contents, and therefore heedless of appearances. It was cynically suggested, however, that possibly the whiskey had been emptied into a jug and that the appropriate soda water was being carried home to impart medicinal properties to the mixture.

Pike's Peak Rack Railway.

At the upper end of the main street of Manitou and at the terminus of the electric railway, is the station of the Manitou & Pike's Peak Ry., the celebrated rack-rail line, which has been fully described and illustrated in Engineering News. It was built in 1889-1890. This line attains an elevation of 7,518 ft. in a length of about nine miles (47,992 ft.), having an average grade of 16% and maximum grades of 25%, and the summit being 14,147 ft. above sea level. The sharpest curves are of 16° (or 359 ft. radius). The scenery is most grand and picturesque, especially as seen from some of the long grades benched out of the side of the mountain, while the views from the summit are beyond descripton. It is, however, not such a thrilling ride in some respects as that up the old Mount Washington Ry., for the latter, though by far the shorter and reaching only to 6,293 ft. above sea level, has heavier grades and a number of long high trestles, while it is built among grim-looking grey and black rocks. The Pike's Peak line has no trestles and only four short plate girder bridges, and the rocks and scenery are of a more cheerful color and character than those of the White Mountains. As is well known, the Pike's Peak Ry. has the Abt rack-rail system, with double rack bars (the teeth of which are lapped or staggered lengthwise of the track), while the Mount Washington Ry. has the old ladder rack of the Marsh system, which is erroneously known in Europe as the Riggenbach system. The teeth of the rack-bars show very little wear beyond a slight burr on the top of the up-grade face, indicating the flow of metal under pressure.

The running track is laid with 40-lb. rails, having square three-tie joints spliced with 38-in. angle bars and six bolts, but owing to the creeping of the rails some of the joints are now suspended. There are 18 pine ties to a rail length, and a row of planks is laid on the ties on each side of the rack-rail, the planks being double spiked to each tie. The ballast is of disintegrated rock, shouldered out beyond the ends of the ties. The track requires constant attention, and there are two section gangs, one of eight men and one of five men. The track gages are marked for the position of the rack-rail. There is not now much trouble from the creeping of the track, the banks having become consolidated and the anchorages having come to a heading. Near the Halfway House were seen the works for the Colorado Springs water supply plant, above referred to, and a view taken at this point was shown in Engineering News of Aug. 27. At the summit is a stone building containing a refreshment room and a room full of souvenirs, but there is no hotel accommodation. A few small patches of snow were seen in crevices of the rocks at the summit. An example of great carelessness was noted near one of the water tanks, where ashes had been dumped and shoveled outside the rail in a pile so high and so near the track that the big end of the main connecting rod on that side struck full into the heap of ashes. None of the men seemed to take any notice of this, however. Each train consists of one long four-wheel car, seating 50 passengers, and a Baldwin four-cylinder compound locomotive, having cylinders 9×22 and 15×22 ins., four main carrying wheels 25¾ ins. diameter and two double pinions, 22½ ins. diameter, for the rack. The engine has a two-wheel truck under the cab. Its weight is 45,850 lbs., with 33,200 lbs. on the driving wheels. The cars have rack pinions for braking purposes. The engine pushes the car up the mountain, and is not coupled to it, the contact between the engine and car consisting of a vertical roller on the front of the engine bumper beam bearing against a horizontal roller on the rear of the car platform. The speed is low, the up trip occupying 1 hour 50 minutes and the down trip 1 hour 30 minutes, with five intermediate stops on each trip. An interesting device seen at the Halfway House was the "toboggan" or "go-devil" on which a man occasionally descends the line, sliding on the rail and having a wedge brake gripping the rack-rail. I have seen such a device used on the Mount Washington Ry., the descent being made at terrific speed.

(To be continued.)

THE PECOS VALLEY IRRIGATION SYSTEM.

By L. B. Howell, M. E.

The valley of the Pecos River in southeastern New Mexico is the site of an irrigation system having at present under its operated canals some 200,000 acres of land. The source of water supply is the Pecos River, across whose bed two dams have been thrown, as shown by Fig. 1, designed for an aggregate storage capacity of 3,900,000,000 cu. ft. The smaller dam, situated six miles above the city of Eddy, was built in 1889-90. A brief description of this dam was given in Engineering News of May 17, 1890. The principal dimensions of the structure were as follows: Length, 1,040 ft.; greatest height above bed-rock, 40 ft.; top of dam, 30 ft. above floor of headgate channel. The dam was rock-filled, having on its up-stream side a rough wall of rock laid with the slope of ½ to 1. Outside of this wall earth was placed to a slope of 2 to 1. This surface was protected by rip-rapping. The slope was afterwards changed to 3 to 1, the original earth facing being washed out. On the down-stream side the limestone filling was allowed to take its natural slope, 1 to 1. Fig. 2 is a general view of the dam and Fig. 3 is a cross-section of it, as rebuilt.

At the eastern end of the dam, at right angles to it, was cut a rock channel, containing, respectively, at its end and side the headgates of the canal and the spillway gates for discharge into the river below the dam. Fig. 4 is a view taken from the dam at a point near its east end, showing secondary headgates, and two spillways. The main headgates are 4 ft. wide by 8 ft. high, sliding in vertical guides and operated by screws from a platform above. The upper spillway, Fig. 5, contains 31 gates, 5 ft. ½ in. in width by 7 ft. 2 ins. in height. These gates, when open, discharged at 13 ft. above floor of headgate channel, and when closed, discharged at 10 ft. below top of original dam. Fig. 6 shows the details of a spillway gate, with its releasing apparatus. Each gate is hinged to swing horizontally and is unlatched by a blow on the vertical releasing rod. When the gates are to be closed, the water is diverted by flash-boards, dropped above the gates. Below the main headgates is a set of secondary gates for diverting the water through the lower spillway, which is 61 ft. wide. At the west end of the dam, a spillway, 200 ft. in width and having no gates, was cut in the rock. It discharged water at 7 ft. below top of dam.

A feature of the construction was the tunnel or scour channel piercing the dam at a point near its eastern end, and at a depth of 9 ft. below the headgate channel floor. A gate was placed at the upper end of this scourway and was operated by a vertical screw 36 ft. in length.

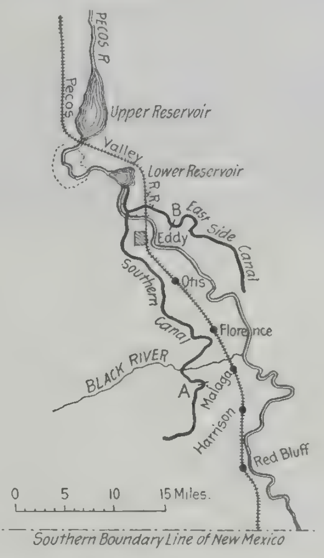

Fig. 1.—Map of Pecos Valley Irrigation System, Eddy, N. M.

It will be seen from the above description of the dam, that its safety depended entirely upon the ability of the spillways to keep the water below its crest. No attempt was made to build a structure able to withstand an overflow. In August, 1893, a heavy flood caused the destruction of the dam, because of the insufficiency of spillway capacity. The water rose steadily, despite the heavy flow through the spillways, and finally poured over the dam, quickly carrying it away. In rebuilding, the height of the dam was increased 5 ft. and its length to 1,135 ft. Its cross-section is shown in Fig. 3. The capacity of the west spillway was increased by cutting it down 3 ft., and widening it to 240 ft. A second rock spillway on the west was added, having a width of 300 ft. Both now discharge at 15 ft. below top of dam, at the same level as the upper spillway at the eastern end of the dam (gates closed). The scourway was found to be of no value and was removed in the rebuilding. The present dam forms a reservoir of 300,000,000 cu. ft. capacity, at the level of the top of the upper spillway gates.

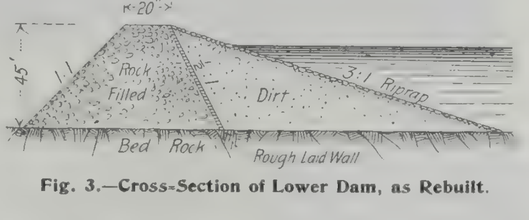

Fig. 3.—Cross-Section of Lower Dam, as Rebuilt.

In 1893 was commenced the second and larger dam. Following the windings of the Pecos, it is situated eleven miles above the lower dam. It is similar in construction to the latter, but of greater length and height, the dimensions being, respectively, 1,835 and 56 ft. As in the present lower dam, the top is 35 ft. above the floor of the headgate channel. Water is diverted into a rock-cut 1,100 ft. long, through headgates, and back into the river bed, which serves as a channel leading to the lower reservoir. The upper end of the rock-cut channel and the headgates are shown by the view, Fig. 7. The headgates are six in number, 4 ft. wide by 8 ft. high. At present water is stored to a depth of only 18 ft. above floor of headgate channel. This level will, however, eventually be raised to 25 ft., or 10 ft. below top of dam. A long earth embankment in continuation of the dam on the west, was built along the shore of the reservoir. At present it contains a spillway 400 ft. wide, which discharges at the 18-ft. storage level, or 17 ft. below top of dam. The capacity at the 25-ft. level will be 3,600,000,000 cu. ft., 8,100 acres to be submerged.

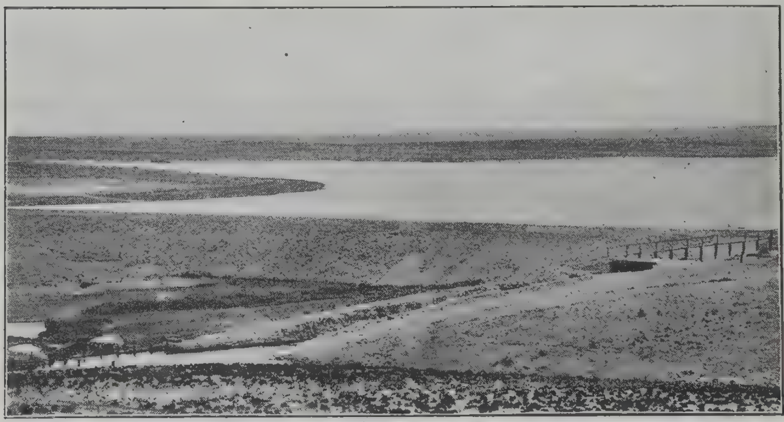

FIG. 2.—VIEW OF LOWER DAM FROM THE SOUTHWEST.

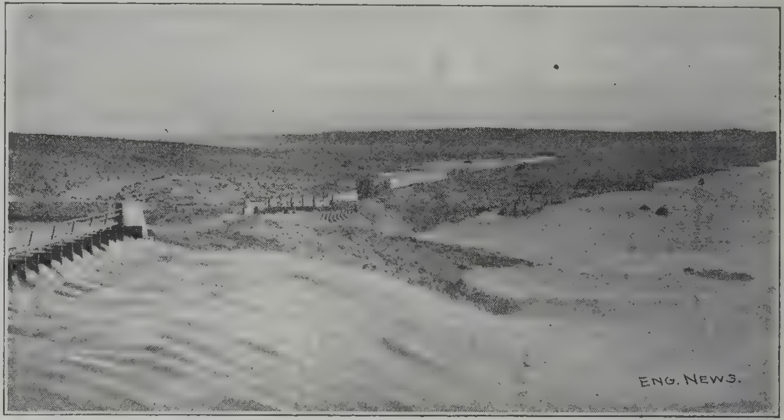

FIG. 4.—VIEW OF SPILLWAYS AND SECONDARY HEADGATES, LOWER DAM.

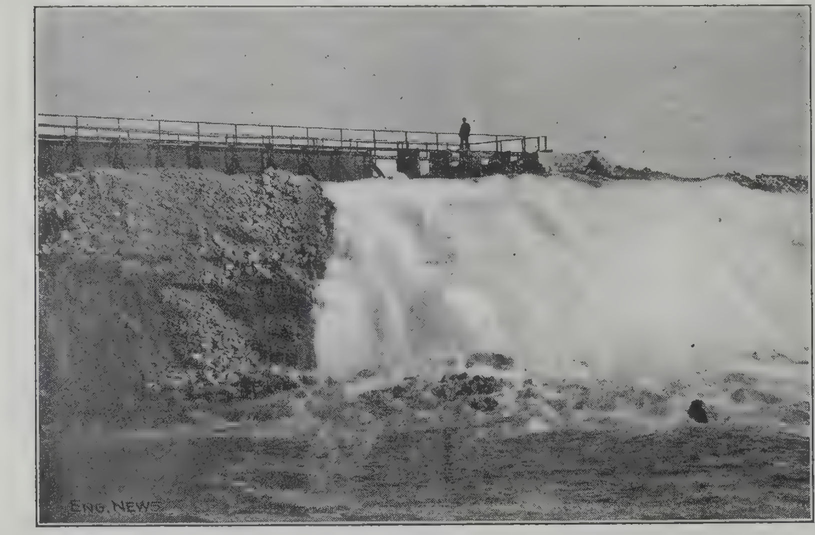

FIG. 5.—VIEW OF UPPER SPILLWAY AT LOWER RESERVOIR.

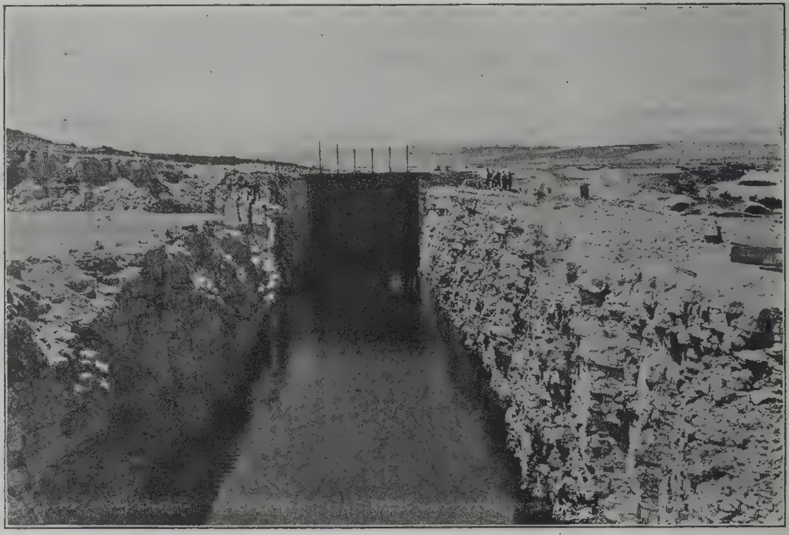

FIG. 7.—ROCK CUT CHANNEL BELOW HEADGATES AT UPPER RESERVOIR.

The lower reservoir has its outlet in a single canal, the first section of which, following the east bank of the Pecos, 3.2 miles, has the following dimensions: Forty-five ft. wide on the bottom, with 7 ft. banks, having a slope of 1½ to 1; capacity, 400 cu. ft. per sec. At the end of the first section, the canal branches, the main portion continuing southward, and a smaller ditch leading in a wide bend to the east of Eddy, as shown on the map accompanying, Fig. 1. The latter is operated at present for a distance of four miles and is completed for 16 miles. Its capacity is 150 cu. ft. per sec. The main branch is in operation as far as the point marked (A) on the map, 31 miles below the lower reservoir, its width on bottom varying section by section from 30 ft. at the point of junction with the "East Side" canal, to 15 ft. at its terminus. The grade of the canal is 1½ ft. to the mile throughout. The Pecos River is crossed on a wooden flume, 468 ft. long by 25 ft. wide. The Black River, 28 miles below the reservoir, is crossed on a similar structure, 1,028 ft. long by 16 ft. wide. Laterals are cut in at frequent intervals and cover the whole area eastward from the canal to the river, a distance which reaches a maximum of about five miles.

Distinct from the system of reservoirs and canals described above, but under the same management, is the "Northern" canal, carrying water to the town of Hagerman and the vicinity. This canal derives its supply from a group of springs situated near Roswell, 90 miles north of Eddy, and forming the source of the Hondo River, a tributary of the Pecos; no storage is attempted. The flow is diverted into the canal by a small dam and continues southward a distance of 38 miles, varying from 120 to 300 cu. ft. per sec. during the rainy season. The grade of the canal is 1 ft. per mile. Nine-Mile Creek is crossed on a wooden flume 330 ft. long by 25 ft. wide. Felix Creek is a dry, rocky bed, except in periods of heavy rainfall, when it becomes a stream of considerable width. An earth embankment 1,000 ft. long and 23 ft. high is thrown up across the river bed. It acts as a dam and as the lower bank of the canal. In each end of the embankment is cut a weir 10 ft. deep through which flood waters escape. The waters of the canal spread out into a small lake at this point, there being no upper bank. The same plan is followed in crossing a dry stream at a point on the southern canal, except that a single weir is cut in the center of the embankment.

When subjected to irrigation, the soil of the Pecos Valley is found to be exceptionally fertile. Fruits, grains, vegetables, all thrive. The land under the canals is controlled by the Pecos Irrigation & Improvement Co., whose headquarters are at Eddy. Water is brought to the boundaries of the farm by the company, all ditches outside being maintained by it. Each section of the canal is in charge of a "ditch-rider," whose duties consist in the maintenance of canal and laterals, the supervision of the supply to the farmers, and, in general, the rendering of assistance and advice to the latter in methods of irrigating. Telephonic connection is maintained between the offices of the company and all parts of the system, including the two reservoirs.

The storage capacity of the two reservoirs is sufficient to supply all the land under the present length of southern canal, as it is gradually placed under cultivation. In all but four months of the year, March, April, May and June, the storage is not now drawn upon, the natural flow of the river being sufficient for the demand during the remainder of the year. An extension of the system will involve the construction of other reservoirs at several points in the Pecos. The first one to be undertaken would probably be situated between the two present reservoirs, as shown on the map by dotted lines. Two other sites have been located, one near Red Bluff, and the second above Riverton, Tex., a canal to be taken out at the latter point.

For the information contained in the above descriptions, the writer is indebted to L. H. Bartlett, Superintendent of Water Service of Pecos Co., Eddy, N. M.

TESTS OF FIREPROOF MATERIAL.

A test of the Roebling fireproof construction system for floors and partitions of buildings was made in New York on Sept. 3, under the supervision of the Department of Buildings. This system has wire netting embedded in cement or concrete, the floors having the netting in the form of an arch between the lower flanges of the floor beams, and sometimes having a flat ceiling composed of a layer of netting attached to the flanges of the beams and covered with cement and plaster. The system was described and illustrated in our issue of July 18, 1895, and May 14, 1896, and is being introduced by the John A. Roebling's Sons Co., 117 Liberty St., New York city, this firm having already applied it in several large buildings.

A small steel skeleton building was erected on a vacant lot at 82d St. and Western Boulevard, having grates for the floor, and having the roof formed of the Roebling arched and flat-ceiling construction, besides which there were two partitions extending from the walls. The fires were lighted at 11:10 a. m., the temperatures inside the structures being recorded by a Uehling & Steinbart pyrometer (Eng. News, Nov. 14, 1895), and ranged as follows:

	Degrees.		Degrees.
11:26 a. m.	1,150	Noon	1,990
11:30 "	1,300	12:01 p. m.	2,000
11:37 "	1,600	12:02 "	2,025
11:42 "	1,800	12:03 "	2,050
11:53 "	1,800	12:04 "	2,100
11:55 "	1,900	12:05½ "	2,125
11:59 "	1,950	12:07 "	2,150

About 12:45 a detachment from the fire department extinguished the fire, using a single hose, the principal damage done being the falling of plaster from the wire, leaving the netting exposed, though the concrete above it still carried the load of bricks piled upon it before the commencement of the tests. One partition, with a single sheet of netting, had collapsed and was nearly stripped of its plaster covering; while the other, with two sheets of netting, though distorted and cracked was still practically a partition. Some of the ceiling plaster fell from the wire during the fire, and some was knocked off by the stream of water from the fire hose.

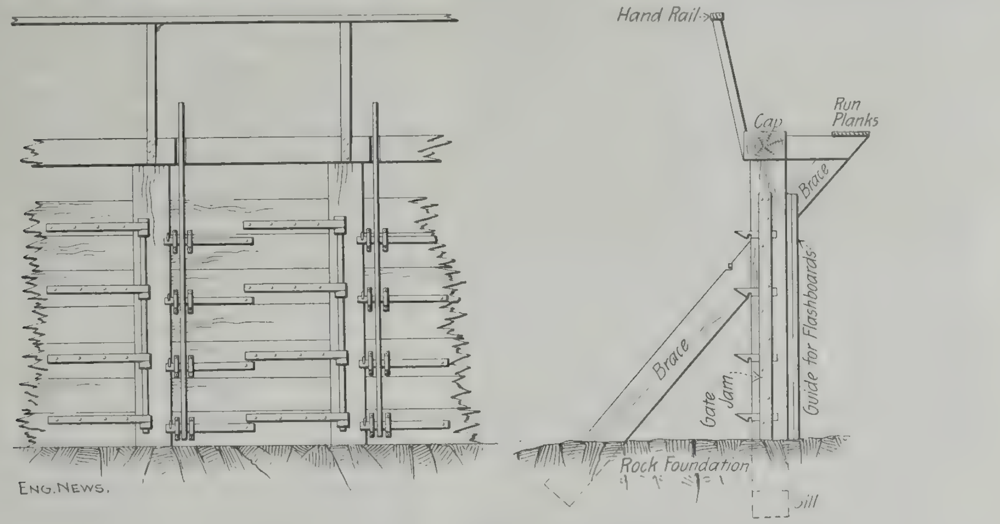

FIG. 6.—DETAILS OF SPILLWAY GATES.

In another brick building, 10 × 11 ft., with half the roof formed on the Roebling system and the other half being 10-in. hollow tiles, all set between 10-in. I-beams, a fire was lighted in the same way, and maintained from about 11:07 a. m. to 12.30 p. m., when it was extinguished by the firemen. On each of these floor arches was a load of bricks of about 9,000 lbs. on a space 4×4 ft., but neither arch showed signs of collapse, though some of the netting of the Roebling arch was exposed by the falling off of the plaster.

After the structure had cooled down the Building Department examined the structure to note deflection of iron work and any other interesting facts connected with the test. It was then ascertained that the iron beams supporting the floors over which was placed the safe load of 150 lbs. per sq. ft., had not deflected, or at least the deflection was so small that it was imperceptible on the readings of the level rod. It was also found that the partitions had buckled through having been placed directly under the iron beams of the floor above and fastened to the brick wall below. There was no chance for expansion and the buckling was a necessary consequence when the heat caused the iron in the partition to expand. Some of the intermediate studs in the partitions were buckled in the form of an S. In one case, where no flat ceiling and air space were used, the wire netting of the arch was practically destroyed, but the iron and concrete of the floor are considered amply strong to carry any safe load, so that in a building there would be no need to rebuild the floors because of the destruction of the netting. In the other building the Roebling floor is said to have shown no deflection, while the flat floor showed a deflection of about ⅝-in. The floors will shortly be tested to destruction by loading.

A similar test was made on Sept. 10 of the system of floor construction manufactured by the Fawcett Ventilated Fireproof Building Co., Ltd., whose main offices are at 448 to 450 Bourse, Philadelphia. This system was illustrated in Engineering News of April 9, 1896 (page 235, Fig. 8). Steel beams are used a uniform distance of 2 ft. apart. Terra cotta lintels of a hollow cross-section are supported on the lower flanges of the beams in such manner that the under side of the lintel is about 2 ins. below the beam. An air space is thereby formed between the lower flange of the beam and the base of the lintel. Above the lintel the space is filled in with concrete.

The test was made in a brick building erected for the purpose, on a lot at the corner of 68th St. and Ave. A. The building was 14 ft. × 11 ft. inside, by 10 ft. high. The roof was formed of the Fawcett floor, 6-in. beams being used, running lengthwise of the building, and the floor being designed to carry safely 150 lbs. per sq. ft. A small chimney was placed at each of the four corners of the roof and a grating was fixed near the bottom, covering the whole inner area. The ceiling was made of common plaster laid directly on the bottom of the lintels, which were grooved with dovetails so as to retain it. Several cords of wood were placed on the grates, some kerosene was sprinkled on it, and the fire was lighted at 9.33 a. m. By 10.30 the pyrometer had reached 1,850° F., and the maximum temperature of 2,200° was recorded at 10.50 a. m. At 11.10 a. m., the wood having partly burned out, the temperature had gone down to 2,000°. The walls of the building had by this time cracked badly from expansion of the brick on the inside. More wood was put in between 11.20 and noon, but the temperature could not be brought higher than 1,850°. When the maximum temperature of 2,200° was reached, the roof, which had been loaded with brick on the two central panels to 150 lbs. per sq. ft. had sagged down about 4 ins., due apparently to expansion of the lower flange of the beams by the great heat. At 12.20 p. m. water was thrown into the building by the Fire Department, the stream of 60 lbs. pressure being directed against the ceiling. When the building had been cooled sufficiently to allow persons to enter it was found that the only damage done was the sagging of the beams, the removal of most of the plaster, and the breakage of the base of several of the lintels. The concrete above the lintels remained in place. On Sept. 11 the test was continued without fire, by adding to the load on the two central panels of the roof up to 600 lbs. per sq. ft. without any further damage being visible. During the fire test the fire did not break through the roof at any point, and the upper surface remained so cool that the hand might be placed upon it.

TELEPHONE WIRES IN WATER-WORKS TUNNELS AND SUBMERGED PIPES.

The importance of prompt means of communication between points on water-works systems separated by water, like intake cribs and pumping stations is obvious. Telephonic communication is maintained at two places of which we know, Chicago and Vancouver, B. C., and doubtless at some others,

The extent of this sort of telephonic communication in Chicago is stated in the following letter from Mr. John Ericson, Assistant City Engineer, written on Sept. 4, 1896:

> The old Chicago Ave. crib, the Four-Mile crib and the 68th St. crib are the only ones so far connected with telephones. The wire to the Chicago Ave. crib is laid in the tunnel and the one to the Four-Mile is also laid in the tunnel. The latter cable was laid part of the way by means of hoisting engines and wire rope, but this being found to be a slow and expensive way, the balance of it was laid by men carrying the cable through the tunnel. This cable has been in good condition since laid in 1892.
>
> The one to the 68th St. crib was laid by means of hoisting engines and wire ropes placed on both the intermediate and the outer cribs. This cable worked satisfactorily for a few months, when it gave out entirely. As it was impracticable to make any repairs to the cable, a new cable was laid on the lake bottom to the crib; this cable is now being used. At Lake View there is no telephone connection as yet, but a cable similar to the one at 68th St. will probably be laid from the pumping station on the bottom of the lake to the crib in the very near future.

The telephone cables at Chicago consist of three wires insulated and wound with hemp, apparently tarred hemp, and then wound with a cover of metal wire of about the size of a telegraph wire.

At Vancouver a telephone was laid in a submerged pipe in a manner which cannot be set forth to better advantage than by the description of the work, kindly sent at our request by Mr. Thos. Tracy, M. Can. Soc. C. E., City Engineer of Vancouver, as follows:

> The pipe through which our telephone cable was laid was of cast iron, 12 ins. in diameter, with flexible joints, and was put together on ways on the north side of Burrard Inlet and pulled over by means of steel cables from capstans on the south shore. In order to lessen the strain on the joints a steel cable, 1¼ ins. in diameter, was placed in the pipe and cinched up tight at each end. When the pipe was in place on removing this cable a No. 16 wire was attached to the end and drawn into the pipe.
>
> When ready to put the telephone cable in, the No. 16 wire was replaced by a No. 6 galvanized wire and by this the cable was drawn into the pipe.
>
> The cable used was a No. 12 copper, insulated, covered with lead and braided on the outside. The strength of it was barely sufficient to stand the strain of pulling in 1,600 ft. in length. For a greater length a stronger cable or a steel armor on it sufficient to stand the pulling strain would be necessary.
>
> If the distance be not too great a line with a number of floats, decreasing in size from the front, attached throughout the length would probably answer. The line could be changed until one was in sufficiently strong to haul the cable.
>
> I would suggest that an additional smaller (loose) wire be drawn in so that in case of a breakage in the hauling wire or cable the whole of the work would not have to be gone over.

At Toronto, Ont., the laying of telephone cables in the submerged pipes across the bay has never been attempted, but telephone service to the island is maintained. Mr. E. H. Keating, M. Am. Soc. C. E., City Engineer of Toronto, describes this service as follows:

> Our telephone service to the caretaker's residence on Toronto Island and the island pumping station is maintained by means of a submerged cable across Toronto harbor. We also have an electric alarm bell at the main pumping station in the city which indicates the limit to which the water is allowed to be drawn down at one of the connecting cribs across the harbor. This service is also operated by means of a submerged cable.

It was once proposed to place a telephone cable in the water intake tunnel at Cleveland, while the intake was in use, but Mr. M. E. Rawson, Chief Assistant Engineer of the Department of Public Works, informed us that the project had not been carried out, but he considered it feasible to do so.

We have been unable to find any other instances of laying telephone wires in submerged pipes or in water-works intake tunnels. Telephone service along pipe lines is maintained in several instances, notably in connection with the water supply of Covington, Ky., and Newark, N. J.

A PHOTOGRAPHIC SURVEYING CAMERA is said to be used with advantage in India, which photographs on the same plate with the picture the magnetic bearing of its central vertical plane. This camera is mounted on a tripod, with leveling screws, and turns on its axis on a horizontal plate with a graduated rim, permitting horizontal angles to be read when desired. On the top of the camera-box is a level and a telescope, with an arm for taking vertical angles. The vertical cross-wire of the telescope bisects the ground-glass screen of the camera. A second vertical wire inside the camera is on the same vertical plane; and the shadow of this second wire is shown upon the plate when developed, making the center-line of the picture. Behind this second wire is a compass, mounted on a rack inside the camera, by which it can be made to just clear the plate when a picture is taken. The graduation of the compass card is carried out on a vertical strip of translucent material through which the light passes to the plate, thus photographing the compass bearing on the plate. A horizontal wire is also photographed on the plate, showing on the picture the true horizon, when the instrument is properly levelled.

ENGINEERING NEWS
AND
AMERICAN RAILWAY JOURNAL.

Published every Thursday at Tribune Building, New York.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; 6 *months,* $2.50; 2 *months,* $1.00; *Single copies,* 15 *cents. To all other countries in the Postal Union, add* $2.08 *per annum* (4 *cents per number*) *to above prices for postage. No club rates allowed. Mailing addresses may be changed at will by sending both old and new address. We shall be obliged if subscribers who fail to receive their papers promptly will notify us without delay. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number* 326 *means that subscription is paid to the* 32d *week* (*that is the issue of Aug* 6) *of the year* 1896; *the change of these figures is the only receipt sent, unless by special request.*

The classic definition of civil engineering in the article on "The Artistic Element in Engineering," in our issue of Sept. 10, was ascribed by the author to Telford, as is usually done, but Prof. Marvin writes us that he has learned that Tredgold was really the author of that definition.

◆

The tests of fireproof floors which are now being made by the Department of Buildings of New York city, will, it is expected, lead to an important increase of knowledge respecting the safety of the so-called fireproof high buildings. The credit for the inauguration of this series of tests is due to Mr. Howard Constable, M. Am. Soc. C. E. He has for the past year or more been studying the subject of fireproof flooring and the methods of testing, and has induced a number of manufacturers to construct samples of their flooring and turn them over to the Department of Buildings for test, according to methods which he has prescribed. The present building law of New York city prescribes that the spaces between all iron or steel floor beams in fireproof buildings shall be filled with common brick or stone arches, or with "sectional hollow brick or hard burned clay, porous terra cotta, or some equally good and fireproof material." Mr. Constable's object is to construct a terra cotta floor which when loaded with its full allowed or safe load shall withstand an intense fire for several hours, and then a stream from an ordinary fire engine without being destroyed or letting its load fall through. When it has been found that a floor of the ordinary terra cotta construction, of sufficient lightness, reasonable cost and good appearance, can be made to stand such a test, then a standard of endurance under test will have been reached to which all the newly proposed styles of flooring will have to conform before they can be allowed by the Building Department.

◆

Our present knowledge concerning the strength and fire-resistance qualities of different floor constructions is exceedingly imperfect. Probably less is known by architects and structural engineers regarding the safety of floors than of any other portion of a building. In Mr. Constable's earlier tests of strength of floors he found factors of safety ranging all the way from 1⅝ to 20. The relative cost of the steel beams in a floor, as compared with the terra cotta or other filling has caused some builders to go to an extreme in increasing the spans between beams, thus greatly increasing the risk of destruction by fire, even though there may be ample strength in the absence of fire. It is to be hoped that the tests now in progress will, among other things, lead to the establishment of rules which will fix the maximum spans for floor sections, and of standards of workmanship for the terra cotta or other filling material.

◆

The tearing up of asphalt pavements for the laying of subway, water and gas pipes, and for sewer connections, is one of the knottiest problems with which the public works departments have to deal. Builders have a right to these connections which cannot be abridged, and corporations obtain rights for street disturbance which the city authorities find it difficult to combat. While it is usually made compulsory to obtain a permit for such work and the parties are compelled to restore the pavement in kind after the break is made, the filling put in almost invariably settles in time and the street surface sinks with it, leaving a long hollow in the pavement. The attempt is now being made in several large cities to appeal to the pockets of the offending parties by making the cost of repairs as excessive as is reasonably possible, in the hope that this cost will discourage any but the most necessary openings. Brooklyn has just framed a regulation requiring not only a proper refilling and ramming of the trench, but also the laying of 8 ins. of Portland cement concrete under the paving surface. It is expected that this concrete will bridge the opening and prevent surface settlement even when the filling beneath does sink. But the new regulation also adds most materially to the cost and nature of the repairs and tends to place this work in the hands of experienced and responsible men, rather than to divide it, as now, among many contractors. Incidentally it may be mentioned that New York city charges $4 per square yard for opening an asphalt pavement, with a minimum charge of $16; and $8 for the first yard of granite pavement—and $4 for each additional yard. The city of Philadelphia charges $13 for a permit to open an asphalt pavement, and increases this amount to $18 between Dec. 1 and March 1 in any year.

In commenting upon horseless carriages, the "Horseless Age," of London, states that it does not believe that any fairly satisfactory vehicle of this type has yet been produced, and gives its reasons as follows: The experiments in France and elsewhere prove that light-oil engines can be used for purposes of locomotion, in this connection. But no vehicle has yet been designed to burn heavy oils without producing a disagreeable smell. The carriages which have made successful runs burn petroleum spirit, benzine or naphtha; materials which necessitate the storage and carriage of a highly inflammable liquid; which does not comply with the laws usually in force, and would make trouble with the insurance companies. The man who is called upon to invest about $1,500 in one of these carriages will properly demand that it be safe, odorless and free from vibration, or comfortable. And the trials of horseless carriages so far made prove that these conditions cannot be secured; in other words, the horseless carriage is not yet a commercial success. Those interested in the design and operation of these carriages, from an engineering point of view, are well aware of these defects, and are striving to remedy them; but others who believe that a finality has been reached and that investment in every horseless carriage scheme that presents itself is a short and sure road to profit, would do well to await further developments.

◆

For some time past engineers in this country have been receiving circulars, inviting them to invest in the shares of the "Civil Engineers Exploration Syndicate, Limited," of London, and these papers eloquently set forth the advantages of this connection. Engineers are told that members introducing business to the syndicate, in the form of patent processes, concessions, contracts or other enterprises relating to the business of an engineer, will be entitled to a bonus of ten per cent. from any net profit derived by the syndicate. Throughout the documents the name of the Institution of Civil Engineers figures prominently, and the Council of that body now issues a circular letter to its members stating that this use is unwarranted by any official action of that body, and it disapproves of the formation of any such syndicate or company because it believes that such a combination among its members, for the purposes set forth, would be undesirable in the true interests of the profession. The chief objections we see to any such organization are that any one can join its ranks, without reference to previous experience or character, and the temptation is held out to weak engineers to indulge in what is properly termed unprofessional conduct. On the one hand, subscription to the shares constitutes membership and enables any designing or unprincipled party to participate in its operations, or, perhaps, to direct them in time. On the other hand, the interest of the syndicate in a patent process, for example, is made the interest of every member of the syndicate, and the temptation is at least strong to recommend the adoption of this process regardless of the true demands of engineering conditions and unbiased professional opinion. An engineer is also often necessarily intrusted with the preliminaries of very important business enterprises, the divulgence of which, in advance of the interests of its promoters, may be made a subject of barter under the terms of the syndicate's prospectus. Happily, the trust thus reposed in the engineer is very seldom betrayed; but the self-respecting engineer will carefully avoid placing himself in a position where he could possibly be suspected of so doing. Channels are already open for doing legitimately all that the syndicate proposes to do, and with the Council of the Institution of Civil Engineers we believe that such an organization as is proposed is opposed to the true principles and best interests of the profession of engineering.

THE RELATIVE SIZE OF THE TRADING WORLD IN 1860 AND IN 1896.

Reduction in time and cost in the transport of goods are the two important factors in promoting international trade, or even an exchange of commodities between different parts of the same country. Both of these items have been enormously reduced within the last thirty years; and the relative distances between trading centers have decreased to such an extent, as compared with the available means of a generation ago, that the world may be said to be much smaller now than then. For all trade purposes San Francisco, at the present time, is about as near to New York as St. Louis was in 1860, and the events and issues of all nations, political, commercial and financial, are known to us almost as soon as they happen. The forces at work within this period have tended to unite the various divisions of the earth to such an extent that anything seriously affecting one part must be felt throughout the whole; and this unity of interests should be taken into consideration in any attempt to deal with problems brought about by a universal and radical change in conditions.

The law of trade is a natural law of supply and demand that expands with the facilities for manufacturing and exchanging goods; and the causes that operate and produce effects in a limited field will extend over a wider territory just as the means for so doing are developed. Within the period in question our scientific, engineering and general material advance has been phenomenal in the history of the world; and it is with this advance that we now have to deal as typified in the effect upon commerce of the extension of railways, the growth in sea tonnage and the shortening of routes of trade.

If we take any date anterior to the introduction of railways, or previous to 1825, we may safely consider each nation separately, from a manufacturing and trading point of view. Each supplied its own wants, mainly from material and labor within its own borders, and was little affected by what its neighbor was doing in a similar line. Foreign trade was practically confined to the import of the luxuries of life and commercial rivalry could hardly be said to exist; at least, from the present point of view. Without railways at all and with highways in a generally very bad condition intercourse was limited within the boundaries of anyone state; and the centralization of population, so characteristic of the present age, was impracticable, owing to the lack of means for supplying such centers with food and other necessaries of life. Up to 1825 the processes of manufacture were still generally crude and closely followed the practice and traditions of a more remote period. The volume of foreign trade was then relatively large; but this trade was conducted in comparatively small and slow ships and over seas imperfectly known. The advent of railways and the gradual development of the steam engine and of processes of manufacture brought about a decided change; but even up to 1860 the broad effects of this change were only beginning to be felt, as compared with present events. Clipper-built sailing ships 34 years ago outstripped the paddle-wheel steamers on the ocean in the race for foreign markets; and on land railways were, to a large extent, being pushed forward into undeveloped regions, with the resultant growth yet to be realized.

It is not necessary to review in detail the several stages by which the conditions controlling trade and manufactures throughout the world have been so radically changed within little more than three decades; but some comparative statistics will enable us to more fully realize the effect of these changes. The year 1860 is selected as a somewhat arbitrary but convenient point of departure; though it should be said that the forces that have since yielded such brilliant results were quietly at work before that date and the ground was being prepared. In any comparison of relative progress in the world the increase of population comes first; because in these more peaceful days this increase compels as well as encourages development in all directions by the necessity for finding food and work for the new millions. Scientific and engineering progress, within the dates mentioned, has had its origin in Europe and North America, and for this reason the population of these countries is alone considered in the summary to be here presented. This aggregate population was 322,600,000 in 1860, and was about 446,000,000 in 1890, a gain of 123,400,000 people in 30 years. The population of Asia and Africa, now estimated at nearly 1,000,000,000, had little or nothing to do with bringing about present progress; but it enters into commerce as an important factor in inducing western nations to manufacture for these teeming millions and to utilize the cheap labor found there in supplying raw materials for general consumption. Were this Eastern population ever to advance to a competitive point in intelligent productive capacity, the effect upon the rest of the world can only be guessed at by political and social economists; and that there are possibilities in this direction the sudden rise of Japan to the position of a power among nations is a sufficient indication.

This gain of 123,400,000 in the civilized population means a vastly increased productive capacity; but, for reasons already stated, without a corresponding increase in the means of manufacturing and handling goods this growth in numbers would have little or no effect upon commerce, national or international. In considering the means actually provided in this interval, railways may be safely classed as one most potent factor in the new growth. In 1860 the aggregate length of all the railways in the world was about 66,290 miles, and these lines were almost wholly confined to the older and more settled parts of the world's surface. In 1893 this mileage had increased to about 390,000 miles, a practically sixfold gain in 33 years. The immediate local effect of this railway construction, coupled with the general development of manufacturing processes, was gradually to decrease the cost of producing and handling goods and vastly to increase the comforts of travel and of living. But aside from this and almost more important in its bearing upon the world at large, was the gradual opening up to civilization and to cultivation of vast areas of what was previously waste and inaccessible lands. To the railways built west of the Mississippi River since 1865 we owe the mineral and agricultural development, which has already added so enormously to our national wealth. And to the extension of railways into the heart of the Argentine Republic, into India and Russia and now across Siberia, we are indebted for a rivalry in the markets of the world that has materially reduced the profits upon our own grain and cotton. In several of these sections development upon modern lines has only commenced, with railways as a basis of operation, and what the ultimate productive capacity of these regions may be we have no means of even estimating. Our only consolation is that the consumers are also rapidly increasing throughout the globe, and it is a fairly well established law that the volume of the product consumed increases with the advance in civilization and even faster than the means for supplying the demand.

When the direct local effect of railway extension upon trade is to be considered, we can best study this in our own country where fuller statistics are available for this purpose. And as the railway mileage of the United States is nearly equal to half of the total world's mileage, it is natural to assume that conclusions based upon our own experience would indicate general results and tendencies elsewhere. In 1860 the railways of the United States aggregated 30,630 miles in length, as compared with an aggregate of 179,280 miles on Jan. 1, 1895. This is an increase of 148,650 miles in 34 years, or more than twice the total world's mileage in 1860. In the fifteen years between 1880 and 1894, inclusive, the mileage of railways in the United States increased 93,726 miles, an average of 6,248 miles per annum; and in the first five years of this period the net increase was 40,759 miles, or an average of 8,152 miles per year. The effect of this rapid extension of carrying capacity can best be indicated by comparing rates and tonnage for certain intervals, and for this purpose the following figures for 1882 and 1894 are taken from the last issue of Poor's "Manual:" In 1882, the 114,461 miles of railways then in operation moved 360,490,375 tons of freight, with a tonnage mileage of 39,302,209,249 miles, and earned $485,778,341 for this service; equivalent to an average of 1.236 cts. per ton-mile. In 1894, 179,280 miles of railway moved 675,129,747 tons, with a tonnage mileage of 82,289,400,498 miles, and received for this work $700,477,409, or an average of 0.851 cts. per ton-mile. In the thirteen years, 1882-94, the total freight movement of all the railways of the country reached the enormous aggregate of 843,365,482,911 tons, and for this service the railway companies received $7,856,765,284. But had the average rate of 1882 prevailed throughout this whole period the public of the United States would have paid, in excess of the above amount actually charged by the transportation companies, a further sum of $2,567,232,085, averaging nearly $200,000,000 per annum. Whether this material reduction in rates in thirteen years be ascribed to more economical administration, to the increase in the volume of freight, to the attempt to secure traffic by cutting rates, or to any other cause, the gain to the public is evident enough. But it may be broadly stated that the growth of facilities for handling and transporting goods, joined to an intelligent economy in operation, tends to increase the volume of freight moved and to decrease the average charges upon this traffic. As an apt illustration of what modern appliances and conveniences for handling certain classes of goods will do in this direction, we have the cost of mining and shipping iron ore from some of the Lake Superior mines. Ore from the Mesaba mine is placed upon the cars at the mine at a cost of 20 cts. per ton, not including a royalty of 25 cts. per ton; but with this initial cost of 45 cts. at the mine it is transported over nearly 100 miles of railway, transferred to a steamer and taken over 780 miles of lake route to Cleveland, O., and there landed upon a dock for $2.25 per ton, every charge included. The average ton-mile rate on the railway was about 0.95 cts. in 1894; but the lake-rate, at 85 cts. for nearly 800 miles of transportation is but little more than one-ninth of the railway rate per ton.

Alongside the railways and under the seas is the electric telegraph, another strong factor in extending trade throughout the world by providing a means of quick communication. Of its social and political importance in furnishing us with the world's news of the day, mention has already been made, but who can measure its value from a commercial standpoint? In the slow-going days of sailing ships and stage-wagons all communication was by letter, subject to the accidents and delays that these means of conveyance imply. Business was conducted in a more leisurely way a generation ago, and months might elapse between the sending of an order and its execution in some distant part of the globe. With the telegraph and the telephone in every counting-house, the whole method of transacting business has altered. Space is no longer a bar and the element of time has almost disappeared in the transmission of advice or orders.

Statistics of the extension of the telegraph throughout the world, between 1860 and the present time, are not available; but they are not needed to impress upon the reader the wonderful importance of this agent in the sending of news. But for the telephone, much more recently introduced, it may be said that there are now over 200,000 miles of wire in operation in the United States alone, and in 1893 175,000 subscribers had over 500,000,000 "talks" with each other. Ten submarine cables connect Europe with North America, under the Atlantic Ocean, and another cable ties Brazil to Spain and the rest of the Old World. Other cables traverse the North Sea and bounding the western coast of Europe, pass through the Mediterranean on to India and the Far East.

Up to this point all that has been said refers mainly to the increased facilities for transport and communication on land; but the change in conditions for moving freight over the seas has been equally great and has had an even more important bearing upon the trade between nations. In the last 30 years the total carrying power of the shipping of the world, steam and sails, has increased from 13,770,000 tons to about 49,000,000 tons; and while the sail tonnage has gained over 1,000,000 tons in this period the chief growth has been in the steam tonnage, which was 764,000 tons in 1860, 7,400,000 tons in 1886, and is doubtless considerably over 8,000,000 tons at the present date. Between 1885 and 1895, 1,500,000 tons have been added to the displacement tonnage of the merchant marine of the leading commercial nations; a gain of over 9 per cent. in ten years. This rapid increase in steam tonnage has been the direct result of the cheapening of production by new processes in metallurgy and of the wonderful late development in the design and power of marine engines, with a corresponding economy in fuel consumption and general operation. The nominal horse-power of the engines of the "Great Eastern," launched in 1859, was 2,600, and this engine-power must now be contrasted with the 31,000 I. HP. of the "Campania." Ships of 8,000 tons and more are built to carry freight alone; and these vessels now swarm in every sea, with the natural result that the struggle for cargo and the general cheapening of the cost of transport has reduced freight rates to an unprecedentedly low figure.

With these improved facilities for the interchange of goods it is not remarkable that international trade has more than doubled within about 30 years. Mulhall, in his "Statistical Dictionary," places the approximate value of the combined imports and exports of the world at $7,445,000,000 in 1860, and at $16,885,000,000 in 1889. This growth in the volume of foreign trade created a demand for shorter trade routes and has been productive of some of the world's most remarkable engineering feats. The building of the Suez Canal, opened in 1869, shortened the length of the sailing route between Europe and the East by double the length of a continent; and the construction of a similar cut-off through Central America has only been delayed. The Corinth, Baltic and other shorter ship canals have all been built within the three last decades and at some time or another within this time projects have been advanced for cutting through about every narrow strip of land that anywhere separates two navigable and important seas.

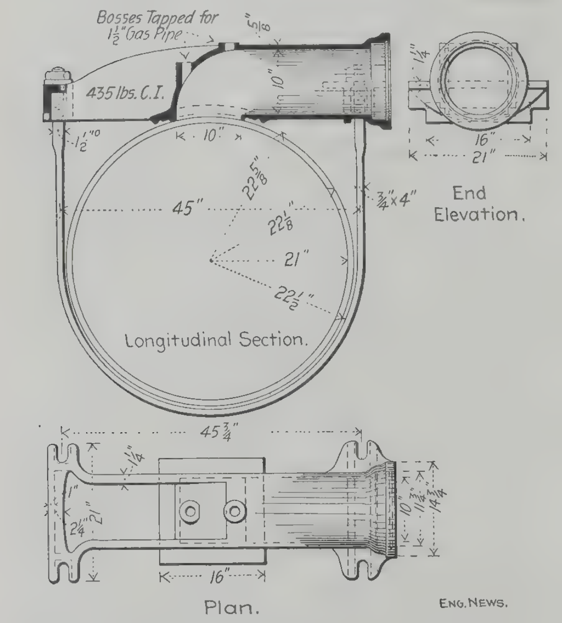
But enough has been said to plainly indicate that while the world's productive capacity, as measured by its gain in population, has normally increased in the last 30 years, the facilities for utilizing this capacity in manufactures and in supplying the world with the product of this labor have grown at an abnormal rate. As before remarked, this world of ours, measured by time and the cost of transport of men and goods from one part to another, is very much smaller than it appeared to be to our fathers. And the immediate effect of this shrinkage is a certain unity of interests throughout the globe and a sensitiveness to events commercial and financial outside of our own country, that never before existed, nor could exist under previous conditions. The wars of conquest and of personal ambition that so long occupied the time and expended the resources of nations, are giving way to industrial wars, within nations and between nations. And in the adjustment which is now going on everywhere the present scientific and engineering advance, which has alone made our material and commercial growth possible, must be well and duly considered.

LETTERS TO THE EDITOR.

Comments on Four Articles Published in Engineering News for Aug. 27.

Sir: There probably has never been an issue of Engineering News that had so many items in it upon which I felt that I could throw additional light as the one for Aug. 27. The first item that attracted my attention was a "Peculiar Break in a Water Main." In "The Technic," published by the Engineering Society of the University of Michigan, 1890, I described a similar occurrence at Greenville, Mich., the article being copied by your issue of Aug. 23, 1890.

The split sleeve described by Mr. Hill has been used in the Detroit Water-Works for nearly 20 years, it having been introduced here by Mr. Henry Bridge, Superintendent of Extension, about 1876. The Smith tapping machine has also been used by us for a number of years, and very satisfactorily, except in the matter of expense. On this account we are now experimenting with a machine of local invention, known as the Howe tapping machine. One of the advantages of the latter is that it is arranged for using any standard gate instead of a special form. It also takes up less room in operation, which is a considerable advantage in streets which are paved and must be resurfaced at a contractor's price per square yard.



Saddle for Tapping Water Mains Under Pressure Used at Detroit.

We have also used here another device, known as a saddle, for tapping mains under pressure, of which I send you a print. The scheme of operation was to fit the saddle to the pipe and mark out the size of the opening, usually 10 ins. square. This was then cut out by drilling small holes, about 7-16-in., around the edge, being careful to drill them tangent to each other or with intersecting circumferences. As soon as the drill, which was wrapped with a cloth, was withdrawn a pine plug was driven into the hole. The swelling of these plugs was found amply sufficient to hold the piece in place after all the iron had been cut away, when working against 40 lbs. pressure. After the piece to be removed was entirely severed from the body of the pipe the saddle was put on and fastened in place by wrought-iron bands coated with graphite paint. The joint between the saddle and pipe was calked with lead and the connection made to the side line from which the pressure was let on and the apparatus tested. When all joints were found tight a steel bar was inserted through a short gas pipe nipple in one of the holes in the saddle directly over the opening. Two or three blows were given the bar with a light sledge and the piece cut out was knocked loose from the wedges and dropped into the pipe while the bar itself was driven out by the pressure of water. A wooden plug was immediately inserted in the nipple, driven tight and cut off flush with the top, after which the cap was screwed on and the connection was complete. As the saddle was already full of water from the side line when the piece was driven in there was no danger of rupture from shock. There were about 25 10 and 6-in. connections made in this way during 1893 and 1894, on 42 and 30-in. pipe lines, all of which have been entirely successful, excepting one in which a heavy sledge was used which broke out a corner of the piece without loosening the whole. After that experience we put in two holes for driving and used a light sledge and were thus able to make a clean opening in every case. The cost of these connections was only about one-tenth that of the Smith sleeve and valve for material and the labor was so nearly the same that there appeared no advantage in either from that point. As a rough-and-ready device for those who cannot afford the more expensive machines it will be found quite satisfactory for connections on large mains. It will be at once seen that the saving in cost over the Smith connection will decrease with the size of main and below 20 ins. there would be little if any economy in it.

Commenting further on the items in your issue of Aug. 27 it occurs to me that the table showing metered and unmetered water consumption at Lexington may be misleading in that the metered consumers do not seem to be charged with their share of the leakage of mains and slip of pumps, if any. You readily see that before meters were introduced this was divided among all taps, but as each tap was metered it ceased to be charged with the source of loss, so that in 1895, 223 taps appear to be bearing the leakage that should be charged to the whole 1,323. As I have thus far failed to obtain any very reliable statistics on the loss in street mains and fixtures from leakage, I doubt if the amount can be satisfactorily determined by guess. While I am heartily in favor of meters I think that over ardent advocates sometimes claim too much for them.

The American patent held by the Joly Iron Works on their stair construction strikes me as being of rather doubtful value, as the U. S. Lighthouse Department has been using practically the same device in combination of wrought and cast iron for the past ten years at least.

Very truly yours, G. S. Williams,
Civil Engineer to the Board of Water Commissioners.
883 East Congress St., Detroit, Mich., Aug. 29, 1896.

The San Juan Route for the Nicaragua Ship Canal.

Sir: I notice in a recent number of your valuable paper an article with map by Mr. J. T. Ford advocating a new route for the Nicaragua Canal. He proposes to dam the San Juan River just below the mouth of the Serapiqui, and thus flood the valley of the San Juan and use it for the canal.

Mr. Ford has evidently not read my article in the "Railway Gazette," published several months ago, in reply to a somewhat similar suggestion from him. In that article I stated that while in charge of the canal work in Nicaragua I caused careful and exhaustive examinations to be made at this locality with this very object in view, and I found to my regret that it was utterly impracticable, as nothing but swamps existed in that vicinity, and no flanking hills or high land for a dam could be found, although the country was examined for three miles in every direction.

There is a high spur of the Cordilleras which comes to the river's edge on the north side at this point, but unfortunately there is nothing but swamp on the south side of the river. Yours truly,

J. Francis Le Baron, C. E.
(Late Engineer in charge Nicaragua Ship Canal.)
Jacksonville, Fla., Sept. 11, 1896.

Timber for Harbor Work.

Sir: I have recently been consulted by a Danish importer of American lumber as to the adaptability and superiority, if any, of red cypress to southern yellow pine, for a bathing establishment to be located in salt water, and which is proposed to be built by the city of Copenhagen in the near future. Not being posted on harbor work in this country, I beg to ask for your opinion in this matter, in order to direct the proper authorities in their selection of American lumber to this or other harbor work in Denmark. At present a North German pine is extensively used, and is protected against the attack of the teredo navalis by thin sheets of iron. Yours truly, O. E. M.
Elmira, N. Y., Sept. 5, 1896.

TIE-PLATES.*

In our issue of Sept. 3, we had occasion to call attention to the important place which the tie-plate is taking in railway track, as an aid to greater efficiency and economy, and it is a significant fact that reports on this appliance were read and discussed at the annual conventions of the American Society of Railroad Superintendents and the Roadmasters' Association of America last week, as noted in another column. We give below an abstract of each of these reports. It will be seen that there is a very strong and general opinion in favor of plates having ribs which embed themselves in the tie, and also a somewhat strong opinion in favor of a rib on the upper side of the plate, to take the thrust of the rail flange in order to reduce the wear or necking of the spike. It is only fair to say, however, that the flat-top plate, without a rib, is far more extensively used than the shoulder plate, and that many persons who have used the former find them quite satisfactory and question the advisability of paying the higher price for the shoulder plate. The two reports are substantially as follows, and some notes of the discussion thereon will be found in another column.

Report of the Committee on Roadway; American Society of Railroad Superintendents.

The committee, recognizing the vast number of subjects connected with the roadway department of a railway that are of interest to you all, has considered it best to select some one of them as the principal subject of its report, the small number of members composing the committee and their inabilty to confer with each other frequently, making it almost impossible for them to cope with more than one of these subjects at a time. The subject of tie-plates is of particular importance to all who are concerned in maintenance of way, and we have made an effort to obtain such information as we can as to what the experience with them has been up to this time, in order to form an idea of what may be expected of them in the future.

You are all, doubtless, so familiar with the various designs of tie-plates that have been and are now on the market, that a detailed description of each can hardly be necessary. The conflicting claims of the manufacturers of each kind of plate, based on arguments that are at first glance so apparently sound, as well as the remarkable difference in the action of the same kind of plates under different circumstances, make it extremely difficult for any of us at this time to determine which form of plate is best for our particular use; and as it takes from five to ten years' experience to determine what good they will do our ties in the way of preserving them, or preventing their wear, a positive conclusion as to what form of tie-plate is the best can only be arrived at some years hence by the lesson of "the survival of the fittest."

One gentleman has stated, in his reply to the inquiries of the committee, that "the relation of the elements composing substructure, superstructure, motive power and character of traffic is so complex that any one kind of plate can not possibly prove satisfactory under all conditions"—and this is possibly true.

The requirements of a tie-plate are, primarily, the preservation of the cross tie, a point on which any argument is superfluous; and the importance of tie-plates as a factor in their preservation and the formation of good track by restricting rail movements is well established. The growing tendency to higher speed of trains and heavier rolling stock is rapidly making the task of maintaining a proper kind of track more difficult and more expensive; and the rapid depletion of our forests by the unceasing and increasing demand for railway ties, more especially hardwoods, and particularly oak, the high price of which in many sections of the country makes it no longer an economical tie to use, makes it necessary that this wood shall sooner or later be replaced by ties made of softer woods, either treated by chemical process to prevent decay, or by mechanical means to protect them from destruction by the mechanical action of the rail; and the tie-plate is, so far, the best means that has been devised toward the accomplishment of the latter result.

The several different designs of tie-plates that have been used in this country are more or less familiar to you all, such as the "Servis," the "Goldie," the "C. A. C.," the "Wolhaupter," etc. These have also been used to some considerable extent in Canada and Mexico, but information is lacking as to the forms of plates used in other foreign countries. An effort has been made to ascertain as far as possible what form of plate is best adapted to American railways, regardless of any particular form now in use, whether or not all of the elements necessary to the desired results are embodied in one plate, or form a part of the composition of many. The qualities necessary in a tie-plate to fulfil the service it is called on to perform may be generally stated as follows:

1. Adhesion to the tie, so that it can be considered as practically a part of it, preventing damage to the wood fiber and rattling by passing trains.

2. Adhesion to the tie to prevent its lateral movement, even on curves of high degree, so that the track can not spread.
3. The above vertical and horizontal adhesion to be obtained by such a mode that it will not assist decay of the tie.
4. It should be so constructed that its application be simple and economical.
5. Its cost should be sufficiently low, so that, when added to the total cost of the tie in place, it will by sufficiently prolonging the life of the tie, pay for itself, due allowance being made for a saving in labor on track repairs, and a better condition of track.

The fulfillment of these requirements should have the following results:

1. Prevent damage to the tie by the rail cutting into it;
2. Make the use of rail braces unnecessary;
3. Make possible the use of soft wood and longer lived ties on curves as well as on tangents, and on all conditions of track;
4. Make possible the use of a tie in the track during its natural life under the most trying conditions of alinement, grade and traffic;
5. Greatly reduce the expense of maintenance of track to proper line and surface;
6. Make possible the maintenance of track in a safer condition, and afford relief to our forests of tie producing timber.

As to how these results may finally be obtained, investigation shows that enough experience has not been accumulated on which to form a decided opinion. A circular was sent to each member of the society, and also to a number of officials of roadway and engineering departments of large systems, who are not members of the society, to all of whom we are indebted for the careful manner in which they have answered our questions. The replies are in such varied form that it is not possible within the limits of this report to give them in detail, but we have selected from them such information, and have quoted the accounts of such experiences as we believe will be of most interest.

The total number of replies received was 73, in which 24 stated that they had not used tie-plates, and were therefore unable to express any opinion at all, and 49 had used them to a greater or less extent.

The number of tie-plates of each kind in use was not in all cases given, and we have no accurate figures as to how many there are. Several large systems of this country and some foreign roads using tie-plates have not been heard from. Ouly four systems that we have learned of have adopted tie-plates for use on their entire lines, one western road having nearly 3,000,000 Servis plates in use, principally on California redwood ties, also on cedar and some burnettized pine and fir. Another has 250,000 Servis plates on cedar ties, and another 293,000 Servis plates on California redwood, each of these systems having had them in use extensively from two to six years, while the total experience extends over various periods of from seven to ten years. A system in Massachusetts has had 300 miles of road equipped with plates for six years. the number in use being divided between the Servis, C. A. C., and Goldie, about equally. Valuable information was received from one southern line that has had 40,000 plates in use for four years, consisting principally of Servis and Goldie, with a few Wolhaupter, the kind of ties used not being stated, but presumably oak.

Accounts were given of the use of 300,000 Servis plates during the past eighteen months on another prominent southern road, and of some extensive experiments with Goldie and Servis plates on one of the northwestern trunk lines, but the majority of those replying to the circular report experiments with all of the different makes, more or less, without showing how many of each kind are in use. As a matter of information, it may be well to state that, where the number of plates in use was specifically stated, the aggregate number of each kind was as follows: Servis 4,565,000, Goldie 1,000,000, C. A. C. 600,000; however, these figures are of uncertain value, for the reason that they do not represent all of the tie-plates in use; yet they indicate a more general use of the form having longitudinal ribs entering the tie parallel with the grain.

So many different dimensions of plates of each kind are in use that it is well that attention should be called to them:

Servis.	Ins.	Servis.	Ins.
2 ribs	3¾ × 8 × ¼	2 ribs	4 × 8 × ¼
2 ribs	5 × 8 × ¼	3 ribs	5 × 7¾ × ¼
3 ribs	5 × 8 × 3-16	3 ribs	5 × 8 × ¼
3 ribs	5 × 8 × ⅜	3 ribs	5 × 8½ × ¼
3 ribs	5 × 8¾ × ⅜	3 ribs	5 × 9 × ¼
3 ribs	6 × 8 × ¼	4 ribs	5 × 8 × 3-16
4 ribs	5 × 8 × ¼	4 ribs	5 × 8¾ × ¼
4 ribs	6 × 8 × 3-16	4 ribs	6 × 8 × ¼
4 ribs	6 × 9 × ¼		
Goldie.		Goldie.	
4 ribs	5 × 6 × ¼	4 ribs	5 × 6 × ⅜
4 ribs	5 × 8 × 5-16	4 ribs	6 × 8 × 5-16
Goldie.		C.A.C.	
4 ribs	8 × 8½ × ⅜	4 ribs	6½ × 9 × ¼

The plates used at joints are generally punched, where necessary, to use spike slotting in splices, and the length of plate is frequently changed to conform to the additional width of the angle bar, although in a number of cases the same plate is used at joints as on intermediate ties. The kind of wood from which the cross-ties are made, the dimension of same, the weight of rail and width of its base, the volume of traffic and character of roadbed all enter into the question of determining what the dimensions of the tie-plate should be. As to the proper thickness of the plate, this question is one that must be determined by experience, although some very decided opinions have already been formed by officials that deserve the highest consideration; for instance, the chief engineer of one line declares that, "only a re-enforced thin plate will perfect a union with a tie, which union is essential to the usefulness of a plate. The vibrations of a heavy plate are sufficient in themselves to loosen them from the tie," while there comes from the manufacturers of a heavy plate (having lugs underneath cutting the grain of wood at right angles) the following argument against such a plate.

"There is not enough stock in this style of plate to stand corrosion and wear, and oppose the crowding of rail with the necessary resistance, for at least 25 years," the inference being that the heavier plate is expected to last that long in service. The latter statement is re-enforced by that of a prominent chief engineer of a system that has been experimenting for the past eight years with a number of different kinds of plates, that, "when made of heavy enough material (⅜-in. thick), the results were good. Where less than ⅜-in. thick, the tie-plates buckled. * * * All these forms of plates were used on steep grades and sharp curves, on heavy drill tracks in yards, and on bridges with sharp curves."

The same gentleman also advanced the following opinion:

> "A tie-plate, to give good results, should have a thickness of at least ⅜-in., should have a shoulder on outside of rail, and should have sharp flanges or lugs to cut into the tie at right angle to the grain without tearing the fiber of the wood. Thin Servis plates have been worn entirely through from rust and friction within three years, and have been buckled in yards under heavy traffic in three months. Plates with no outside shoulder, made of thin metal, also have the objection of cutting into the back of spike heads on sharp curves."

And yet there are quoted below accounts of experiences from which opinions are given in direct opposition to those expressed above:

> "The Servis 3-ribbed plates were placed on ties in M——— tunnel and were in service 3½ years and were completely worn out, in many cases only the ribs remaining, and these so firmly imbedded in the ties that it was almost impossible to remove them. The test of these plates was severe, as in addition to the wear from traffic, they were subject to corrosion due to gas and water. If used outside of the tunnel they would probably have lasted five or six years."
>
> "We have an example of the use of Servis plates at G——— three years. They were put down on the inside of a 10° curve to prevent the rail from rolling over. These ties are now in condition to give three years more service, while the adjoining ties, which were new when the plates were put down, are in such a condition that they will have to be removed this season. * * * We have used Servis tie-plates as above mentioned, and have now adopted Goldie plates as our standard, size 7 × 6 × ⅜ ins. These are known as shoulder plates."
>
> "A section of track 2,500 ft. long, which is a combination of sharp curves and tangents (a loop track whose alinements were confined by existing improvements, mansions, etc.) where we had from four to five men constantly employed gaging and surfacing without any satisfactory results, but since the tie-plates are in use, the track does not require any more attention than other sections. We have also reduced our track force at the rate of about one-half man per mile, but attribute this as much to the more settled condition of the roadbed after five years' running than to the use of tie-plates exclusively. We are saving in the cost of ties by making worn ties do their work by the aid of tie-plates. We save in the retamping of ties, otherwise consequent to changing of ties, which naturally always destroys the tamping. * * * It was the unsatisfactory work of rail braces on sharp loop track curves which prompted us to use the combination tie-plate." In this case, the Servis plate is referred to.)
>
> "Plates were put on bridge ties. * * * Ties that were put in lasted for two years. New ties put in (where ties before lasted two years) were protected with tie-plates and have been in five years, and are in good condition. Ties (that previously lasted four years) when renewed were protected with plates, and now show no perceptible signs of wear after three years' service. * * * Servis plates on oak ties maintain a perfect union with the tie; on cedar ties, they do not under a light rail with heavy traffic, but do so under a heavy rail. The Fox plates break between the slots, and the parallel flanges under the rail shear off. The C. A. C. plates rattle. The Wolhaupter, I can not say anything in regard to, as we have just placed them in the track."
>
> "200,990 were placed on California redwood in 1889, and ties of same wood and in similar soil have had to be removed on account of rail cutting into tie to such an extent as to cause breakage. The life of a redwood tie, without plate, is about six years; tie plates will more than double the life of such ties.
>
> "90,020 have been placed on pine ties, and we figure that it increases the life of such ties 30%, saving in regaging curves in track work, which heretofore has been necessary once a year, thus spike-killing the tie."
>
> "We have found that on curves, our chestnut ties lasted from two to five years longer where we have used plates, but we note the greatest saving where we have used them in the leads of our busy yards. In one yard in particular where we were obliged on account of the heavy traffic to renew the switch timbers every two or three years, when rebuilding this yard four years ago, we used tie-plates, and as yet the timbers do not show any perceptible wear. * * * We first used the Servis tie-plate, but are now using the Goldie principally, size 5 × 8¾ × ⅜ ins., and 5 × 7¾ × ¼ ins. We have favorable results from both longitudinal ribs and with lugs cutting the grain at right angles, having adopted the Goldie in preference to the Servis on account of the shoulder and thicker plate that we are able to secure."

The engineer of maintenance of way of a line having used both forms of plates extensively, writes as follows:

> We have never found either the Goldie claw plate or Servis rib plate loosening from the tie; that is, the union has always seemed to be perfect. While I think the bottom of the longitudinal ribbed plate is better than the Goldie, the shoulder is of greater value, and for this reason prefer the Goldie plate. We find that the lighter the rail the greater the proportional value of the plate. I think that some time there will be a plate made that will combine the longitudinal rib and the shoulder on full width of the plate. This, I think, will be accepted as the standard plate when made.

(The above is from an official of a road that uses cedar ties exclusively.)

The following is from a letter from the engineer of maintenance of way on a different portion of the same system, on which cedar and burnettized hemlock ties are used:

> "Our objection to the Servis plate was that we found that they did not adhere to the tie under all conditions. This was demonstrated by some of the plates on a few curves put in during the previous four years. We found that the plates had moved in the grain of the wood as much as half an inch, spikes and all moving with them. Thus far, we have found the plate with lugs or claws all right, but as our experience with the latter has not been for more than a year, we are not satisfied as to what the result may be after several years' service."

It is possible that in the last case referred to, the ties were of such soft wood, and the other conditions were such, that they would not act well under any circumstances; however, this is merely a surmise.

It is observed that where a very positive preference is expressed for a particular kind of plate, it is often the case that no experience has been had with any other form, which is a good argument for tie-plates in general, but not a strong one for the superiority of one form of plate over the other. There are some notable exceptions, however, where, after having made extensive experiments with several kinds of plates, one particular form has been finally adopted. These cases are deserving of the most serious consideration.

By far the most important feature of a tie-plate is the means by which its contact with the cross-tie is maintained, and, naturally, on account of the different means employed in the various makes of plates, there is more diversity of opinion as to this feature than any other.

The question is mainly, whether the union of the plate with the tie shall be secured by ribs entering the tie parallel with the grain, or by lugs or claws entering the tie at right angles to the grain. Of the 44 opinions received on this point, 28 declare their unqualified preference for the plate with longitudinal ribs, 8 are equally as positive in their preference for the other form, 3 appear to be as well satisfied with one as the other, and 5 have not yet formed a positive opinion either way.

Some of the principal arguments advanced in favor of a plate with longitudinal ribs are as follows: It adds materially to the stiffness of the plate; it excludes water, etc., from between the tie and the plate because of a closer adhesion; it does not weaken the tie by cutting the fiber; it is more easily adjusted. Some of these opinions are quoted in full as follows:

> The track can be re-arranged better and at less cost with plates with longitudinal ribs than with plates which cut the fiber at right angles.
>
> Where the ribs enter the wood parallel with the grain, they simply push the fiber to one side in entering. The fibers immediately begin to close up around the ribs, and in a short time, the iron ribs and the fibers of the wood adhere so closely that the plate can not be pulled out of the tie without bringing some of the wood fibers with it. On the other hand, any projection entering the wood across the grain cuts the fibers, leaving a gaping hole which never closes up, and the plate can always be easily removed from the tie, and in fact, is apt to be loose and to rattle at any time. This can be very simply and clearly shown by an axe. If a sharp axe is driven into the tie across the grain to the depth of one inch and left there, it will be very apt to fall out of itself in a short time, but if it is driven to the same depth parallel with the grain and left there for a day or two, it will be hard to pull out.
>
> 1. The ribs entering the tie do not cut the fibers, but simply compress them, and these compressed fibers are continually re-acting on the ribs, thus holding the plate firm.
> 2. The weight of trains on these does not tend to elongate the fibers, but to spread them laterally. This increases the pressure of the wood against the longitudinal ribs, and keeps the plate and tie permanently bound together.
> 3. When the tie begins to decay (when a plate is of most service), the longitudinal flanges hold the soft fibers of the wood together, thus prolonging the usefulness of the tie.
> 4. The longitudinal flanges give a better distribution of a given amount of metal for strength, and allow plates to be made thin enough for elasticity.

On the other hand, one superintendent expressed the belief that the tendency of the longitudinal ribs is to split the tie, but this theory is not supported by any argument that we have seen. It is claimed by those who prefer the tie-plate with lugs or claws cutting the fiber at right angles that they are more easily applied than the other kind; and it may be noted that this same claim has been made for both forms. One writes in regard to the Goldie plate as follows: "This form is best for the reason that lugs across the grain hold the plate tight to the tie, and offer more resistance to the movement of the plate, and do not tend to split the tie as does the ribbed plate parallel with the grain," while the following arguments have been received against any form of plate having lugs that cut the fiber at right angles:

> Every pressure of the plate would have a tendency to compress the fiber of the tie, and thus cause a larger

> space in which the lug could work, resulting in a loose plate.
>
> They are decidedly not suited to the softer woods.
>
> The object of a tie-plate is to prevent the rail cutting across the fiber, or in reality to prevent what a plate with lugs actually does.
>
> It is not desirable, such plates without stiffening ribs have to be much thicker and therefore heavier and more expensive in order to give satisfactory results. We do not think a plate with lugs cutting the grain at right angles will adhere as well as the other.
>
> I have noticed that where lugs are used, the plate is apt to bend so that the lugs at one end of it only enter the tie, and the result, of course, is unsatisfactory.

A claim of the makers of the C. A. C. plate is that "the re-enforced lugs directly under the center of rail-seat insure quick penetration into the wood, and as they do not come to the edge of the plate, but are covered on all sides by a good margin of metal, no water can get in to soften the fibers of ties, loosening the hold of the lugs. Lugs thus interiorly placed are not only more effective, but lessen the tendency of the plate to sag in the middle, as in the case of that form of plate with lugs bent down at edge of plate, or at corners."

As to whether or not a tie-plate should have a shoulder on the outside of rail to relieve the spiking, and assist in maintaining the gage, it seems to be the general opinion that such a shoulder is desirable, although a large number of engineers and other officials who have used plates with no shoulders are of the opinion that it is unnecessary. It does seem, other things being equal, that a plate with a shoulder on the outside of rail, and especially one with a shoulder extending entirely across the plate, would do more toward keeping the track in gage and lessening the wear on spikes than one without such a shoulder, and that a plate so constructed would be of particular benefit on curves. The statement is made by some that a plate without a shoulder at all is not a complete rail brace, "as the fibers of the tie are too soft to offer sufficient resistance to the spreading of gage;" however, this opinion may have been expressed with only a view of using ties made of soft wood. Only a few superintendents claim that rail braces cannot be entirely dispensed with on sharp curves, while it is the most general opinion, so far as we are able to learn, that tie-plates fully perform the functions of a rail brace, and are in fact an improvement on them. For instance, one states that "they are very effective in preserving gage and saving spiking on account of ribs (uses the Servis combination plate) entering the tie and furnishing sufficient resistance so that the track in which we have laid four consecutive ties with plates without spiking on a 9° curve with a 5-in. elevation, the gage was perfectly preserved."

Another states that he "considers them better than braces, as the plate holds the rail perpendicular, and makes a more uniform surface wear, and so prevents scaling, prevents the rail spreading, which, with 60-ton engines on curves at fast speed, is not overcome by braces on every second tie on curves of 8° and over, and every third tie on curves of less than 8°." A very clear explanation of the action of a rail brace, as well as a good argument in favor of tie-plates was given us by Mr. J. A. Dodson, of the Southern Ry., as follows:

> The centrifugal force exerts a strong pressure on the head of the rail, tending to revolve it about the outer edge of its base. This unequal bearing of the rail on the tie, combined with the sawing or abrasion of the tie from the rail flexure as each wheel passes over, soon depresses the outer edge of the rail into the tie, thus destroying its vertical position. This is a tendency which may be retarded, but cannot be counteracted by a rail brace; a rail cannot turn over until the outside of base is lower than the inside. When the tie becomes cut at the outer edge of rail base, the brace is forced into the tie at its edge nearest the rail and slightly draws the spike at the side remote from the rail. When such a condition is reached, which does not require any considerable length of time, the flange of each wheel begins to shave the head of the rail on the gage side, which is destructive to both rail and rolling stock. The only remedy is to draw all the spikes, adze the tie and prepare for a repetition of the same trouble. By using tie-plates, the cutting of the tie is stopped, the rail is maintained in an upright position to gage, and all trouble from this source vanishes. The saving in ties, rail, wheels, spikes and labor is considerable, sufficient to pay for the tie-plate several times.

As to the effect on spiking, there appears to us to be reasons why a plate with a shoulder should be more beneficial than one without it, provided the plate is so constructed that the only function of the spikes that is left is that of holding the rail down to the ties. There can be no doubt, however, that any of the plates in question, either with or without a shoulder, will have a beneficial effect on the spiking, as the punched holes of the tie-plate insure the spikes being driven vertically, for men will naturally exercise more care in starting and driving them; first, because the plates require it, and second, because improper spiking is more easily detected if the spikes are not driven vertically, and any attempt to straighten the spikes by hitting them with a maul will only make matters worse. The spike holes, however, should be of such a size and position that the spikes shall fit the rail flange snugly in order that the spike heads shall have the proper hold on the rail. On some roads where plates having no shoulders are used, three spike-holes are punched so that two spikes can be used on the outside of rail, with very satisfactory results as to keeping the track to gage. No considerable use seems to have been made of plates of a bevel or wedge-shaped form, but some manufacturers have recommended them "to give the rail an inward inclination and at the same time increase the thickness of the plate at the shoulder, thereby increasing its stability, and reduce the flange-wear of the rail heads."

One official reports having used such plates, but says that they are at present using the Servis plate both on curves and tangents. considering it for all purposes as good as the wedge-shaped plate. One or two members have recommended a plate with a bevel of from 1-16 to ⅛-in.

A very few objections have been received against the use of tie-plates on heavy grades, the possibility of bad results being suggested from the "reducing of friction contributing to the rail running down hill." One suggests that "if spikes are allowed to raise up, the rail would creep more readily on a steel plate than on wood, and where the force is small, spikes will work up," but it is not probable that there is much foundation for such an objection.

As before stated, it may properly be said that all of the different forms of plates mentioned above have their good points, but it would not be safe at this time, considering the comparatively short experience that has been had with them, to condemn or to approve of either kind. It is possible, as was before suggested, that no one form of plate yet devised will give perfect results under all conditions, yet it appears that a plate combining longitudinal flanges entering the tie parallel with the grain and a shoulder on the outside of the rail, would be most desirable. That tie-plates, as one of the most important features of track equipment, have come to stay, there is no doubt; and that they are of special value on sharp curves and heavy grades; in tunnels, particularly where wet and where the difficulty of securing good track is great because of the softening of the ties by the action of water, gases, etc.; in yards where there is constant switching and heavy traffic; at platforms in front of stations; and in street crossings where the ties are kept soft by moisture, and where it is both difficult and expensive to get at the track for renewal of ties, re-surfacing or re-gaging; on bridges and trestles, particularly those on curves, and on grades where a great deal of sand is used and where traffic is very heavy. It is possible that in the southern states where oak ties are plentiful and cheap, their use on tangents might not be justifiable, but in the north and west where only soft ties are to be had, or where the price of ties is high, their general use on all kinds of track seems desirable.

The following extract from a very interesting communication from the chief engineer of one of our most important railways is worthy of consideration: "There are, I believe, very few roadmasters who, if they were asked to choose, for general use, between 60-lb. rail with tie-plates and 75-lb. rail without tie-plates, would not select the latter. The cost is about equal."

We have not attempted to go very deeply into the question of the cost of tie-plates, being more particular to consider their mechanical features. Their cost, of course, largely depends on their weight and dimensions and the number used, ranging from 5 to 15 cts. each; but we think it would be more proper for those desiring information of that kind, to obtain it from the manufacturers themselves.

Report of the Committee on Tie-Plates; Roadmasters' Association of America.

The committee communicated with the various manufacturers requesting they be furnished with a sample of their appliance. The Q. & C. Co., of New York and Chicago, furnished the Servis plate; the Railroad Supply Co., of Chicago, the Wolhaupter plate; the Avery Stamping Co., of Cleveland, O., the Fox plate, and Dilworth, Porter & Co., of Pittsburg, the Goldie plate. These plates were taken and imbedded by a hydraulic machine in a new yellow pine tie.

1. Tie-plates certainly hold rail to gage.
2. They prolong the life of soft wood ties from mechanical decay or wear five or six years, and hard wood ties two to four years.
3. They are invaluable on curves.
4. A spike has a better support when used with the tie-plate than without, as the tie-plate gives the spike a required backing.

Practical experience has shown that any form of tie-plate to be successful must unite itself to and become part of the tie. Designs of tie-plates which fail in this particular feature have invariably proved unsuccessful. Most of the tie-plates offered cover this feature, but some of those on the market fail entirely in this regard, and your committee is unable to see where they are of any practical service.

There are three factors working in conjunction with the tie-plate: the tie, the rail and the spike.

In the rail, the wave action causes an alternate rise and drop to a bearing on the tie-plates and thence to the ties; this results in a jumping movement of loose tie-plates if the imbedment is not firm and thorough. This loosening indents the ties, breaking or bending the tie-plates and causing a lamination of the rails. Where the tie-plate fails in the imbedment and causes the above results the remedy adopted by the manufacturers seems to have been to increase the thickness of the plate, which does not prevent the undulation of the rails but adds a heavier plate, and while the tie-plates are saved, the rail receives increased wear, spotting and spoiling the rails. In an experimental test made by the Pennsylvania R. R. in 1870 of a flat plate 6 ins. square and ⅜-in. thick, they acted as an anvil and caused the rail head to show a spot where the wheel struck it immediately over the tie-plate. These plates were not imbedded in the tie and possessed none of the mechanical qualities for imbedment of any of the tie-plates now on the market.* About 1880 the Manhattan Ry. had a similar experience with a flat plate and was obliged to take them out of the track. In fact it had decided to use no tie-plates until those allowing the flange for imbedment came upon the market. It is obvious that any tie-plate that has not a good, firm and secure imbedment in timber, is useless.

Any and every tie-plate should be heavy enough to act as a perfect bearing plate under the rail, but where increased thickness is used either the tie or the rail has to suffer. When tie-plates unite themselves to the ties a much thinner plate can be and is used; for such plates partake of the stiffness and strength of the wood which supports them, that is providing the plate has a full and good imbedment. Your committee finds in reports received that the wave motion of light section rail is much more severe than of the heavier rails, now being generally used, so that any tie-plate found resisting the action of the former has a reserve of strength and can be safely used with the latter. In connection with the matter of heavier rails, it is an error to suppose that the stiffer the rails the more severe the wear is on the tie-plate, or tie supporting them, as on some lines the number of ties used per rail length is reduced when the heavier rails are laid.

In looking over many cut ties it became evident that most of the wear is due to the moving rail and even in the softest woods where indentation was to be expected, there was but little appearance of it. It is here that the tie-plate proves of the greatest service. It prevents the tie from being cut into by lessening the up and down motion and decreases the lengthwise movement with the result that there is less creeping of rail and little or no wear into the tie, if the tie-plate is properly imbedded.

The duty of the spike is to prevent lateral motion of the rail. If imperfect spiking is done this is not accomplished, and to accomplish perfect spiking the tie-plate should have its holes so punched as to allow a close fit of the spike to the rail flange. Where this is not done trouble is experienced in the wear of the parts due to the working in and out of the rail against the spikes. This in connection with the up and down movement causes a wear in the neck of the spike. It is therefore most essential that tie-plates should be properly punched, and no tie-plate should be placed in position unless the tie has been adzed to a true bearing, as the principal cause of tie-plates buckling has arisen from this neglect, for no tie-plate can be a bridge. In connection with this last finding the committee has been struck with the fact that many of the tie-plate manufacturers are placing a shoulder on the plate, and that said shoulder as now used is of little or no value, for when the spike wears the rail gets loose motion and the shoulder and spike both cut. To the mind of your committee it appears if this shoulder were placed the full width of the tie-plate it would offer a support for and reduce the strain on the spike with consequent and better results in the line and gage of the rail.

While considering the three important essential parts which enter into the relation of the tie-plate, your committee fully understand that the tie itself is the principal factor, and have tried to secure information as to results obtained with different woods used with and without the tie-plate. The consensus of opinion seems to be that the life of the cedar tie averages 12 or 14 years, hemlock ties 5 years, tamarack ties 6 years, and oak ties 9 years. The price of ties is so variable in different sections of the country your committee find it hard to strike the average cost, yet in all the reports we have received the invariable answer has been that where the tie-plate has been used, no matter the quality of the tie, it has prolonged the life of the timber from mechanical wear. Furthermore, the committee finds that better results have been obtained from a narrow than a wide tie-plate, and feel that a plate 5 ins. wide is ample for all purposes.

On the second division of the subject matter: "Will the Use of Tie-Plates Dispense with the Use of Rail Braces?" your committee, after a most thorough and searching experiment and investigation, unhesitatingly state they will do so. We have received reports showing where they have proved successful on curves of 3° 30′, 4° 25′, 15°, and even on 60°, where they have held the rail in place without any rail braces being used. Moreover, no lateral movement or cutting of ties has occurred on these curves, and the track is in perfect and true gage.

Your committee has had reports from chief engineers and roadmasters in all sections of this country where ties have been used under almost all possible conditions with and without tie-plates, and the reports received show that the use of the tie-plate is a very necessary appliance on all track work.

---

*It should be stated, however, that the Pennsylvania R. R. still favors flat plates.—Ed.

Its use is economic, as it reduces the repairs on the road bed and makes a more perfect track with consequent reduction on repairs of rolling stock. Further, its use as a measure of safety is beyond question, for it means truer gage to the track. Your committee unite in recommending the general use on all repair and construction work of the tie-plate, and feel that its added cost to the track maintenance will be more than compensated by the cost of labor saved in tie renewals alone.

R. Black, Chairman; J. B. Moll, Geo. W. Light.

A TABLE GIVING THE PERIMETER, AREA AND HYDRAULIC MEAN RADIUS OF EGG-SHAPED SEWERS.

A handy table for use in designing egg-shaped sewers has been handed us by an engineer and is published herewith. The table is based on a sewer having a horizontal diameter of 1 ft. and a vertical diameter of 1½ ft., and gives the wetted perimeters, areas and hydraulic mean radii for such a sewer, with varying depths of flow up to two-thirds of the full depth of the sewer. To apply the table to other sizes follow the directions beneath the title to the table.

Table for Finding the Wetted Perimeter, Area and Hydraulic Mean Radius of Egg-Shaped Sewers Where the Horizontal Diameter is Two-Thirds the Vertical, and the Sewer Flows Not Over Two-Thirds Full.

(For corresponding values of p, a and r for other sewers of like proportions, $A = a \times D^2$; $P = p \times D$; $R = r \times D$; D being the horizontal diameter of the other sewer.)

CONVENTION OF THE AMERICAN SOCIETY OF RAILROAD SUPERINTENDENTS.

The twenty-sixth meeting of this association was held at the International Hotel, Niagara Falls, N. Y., on Sept. 9 and 10. At the opening session on Sept. 9, with the President, Mr. Charles B. Price (All. Vall. R. R.) in the chair, the first business was the reading of the report of the Executive Committee. This report called attention to the new arrangement of the meetings, and to the desirability of enlarging the sphere of usefulness of the society. It recommended a larger number of committees, or a larger number of members on the present committees.

A proper and convenient classification of the committee work would, of course, require considerable study, but the general idea is to let the society's organization for work follow naturally that of the railways themselves, so far as the department coming under the immediate jurisdiction of superintending officers is concerned. It is further recommended that a number of cash prizes (say of $50 each) be offered, either by the committees or by the society, for papers or special reports on a variety of live topics connected with the operating and maintenance departments. These papers should be received early enough to permit of their being printed and distributed in advance of the meeting. In this connection, the committee suggests the propriety of collecting all papers and reports of importance which have appeared in the printed proceedings of the past 25 meetings and publishing the same in permanent form, carefully edited and well indexed, and with such revision as may seem desirable. Such a volume would be of great interest and value to every railway man in the country, and would undoubtedly command a sale sufficient at least to pay the cost of publication.

It may also be worth your consideration to look into the plan, originally proposed by your Secretary, of forming a closer affiliation with representative bodies of railway officials, such as master mechanics, car builders, roadmasters, accountants, etc., who, under the organization of most railway companies, report directly to the superintendent. Such a movement, however, could best be initiated by a meeting of the executive committees of each organization, to look over the ground and report to their respective bodies such recommendations, if any, as may seem to the best interest of all.

The report of the Treasurer, Mr. R. M. Sully, showed the following summary: Balance in hand in 1895, $1,311; receipts, $1,467; expenses, $1,408; balance in hand in 1896, $1,369. The report of the Secretary, Mr. C. A. Hammond, showed that the membership consists of 214 active members, 18 associate and 5 honorary; 5 members have resigned since the last meeting, while 3 have died. The total present membership is 237, a gain of 12 over those reported at the last meeting. Since the last meeting the Society has lost the following members by death: John Adams, General Superintendent, Fitchburg R. R.; Wm. G. Wattson, Division Superintendent, West Shore R. R., and Waterman Stone, honorary member, and the first secretary of the society. Pecuniarily there has been a falling off from last year, more than offset, however, by decreased expenses. Besides the regular reports and proceedings and the papers by members, the Society has within the last few years reviewed, and published in its proceedings, special papers, including the following: "The Improvement of Railway Track," by E. E. Russell Tratman; "Rails and Rail Fastenings," by J. Churchward; and "Roadway Department Economics," by Andrew Morrison.

The next business was the reading of the report of the Committee on Roadway, an abstract of which is given in another column. This report dealt mainly with the now very important question of the value of tie-plates, but concluded with the suggestion that the question of the merits of different processes of tie preservation and the experience with ties so preserved should be taken up by the committee for the next year. In the discussion, Mr. Derr (Erie R. R.) said that he had in use some hundreds of thousands of the Servis plates, and he advocated their use on every tie on curves and on alternate ties on tangents; he did not favor thick plates. Mr. Hammond thought thick plates advisable for yard tracks.

The report of the Committee on Machinery was then presented by Mr. Potter (Flint & P. Mar. R. R.). He explained that the committee believed that the general subject was fully taken up by the mechanical societies, and had therefore prepared a short report on the motive power of the future, referring to electric traction. An abstract of this is given below:

Electric Locomotives on Railways.

We have arrived at a very interesting point in the evolution of railway motive power, a point of transition from old methods and theories to new ones, a point from which it seems possible to almost certainly predict the entire change from steam to a more economical motive agent. Already the electric motor appears as a formidable competitor of the steam locomotive in suburban and inter-urban traffic in many parts of the country, and he who brings himself to believe that the application of electric power for transportation purposes will never get beyond this class of traffic has a very narrow vision of the field of progress. Unless we make the assumption that we have reached the end of progressive development, we must admit the very great probability of the entire suppression of steam by electricity as a motive power on our railways, not only in suburban and inter-urban traffic, but in cross-country traffic also.

Primarily, such change will take place because the perfection of economy has probably already been reached with regard to the application of steam. We have every reason to believe that the steam locomotive of the present day represents the perfection of economy in its peculiar field, or very nearly so, as there are no valid grounds for believing that the application of the principle of compounding will work much of a revolution in economical locomotive practice, and there seems no other direction in which to look with any degree of confidence for a further economical application of steam power.

There is a wide chasm between the actual and the theoretical economy of the steam locomotive, and it is a chasm which the highest talent of the entire civilized world has for many years been trying to bridge. The effort has resulted in the production of a wonderfully perfect mechanism, the modern locomotive. But in spite of its perfection, the modern locomotive is far from being an economical machine when judged by the standard of the theoretical, and the very fact of its perfection is the sign of its doom. There still remains this chasm to bridge, and there still remains the inventive faculty of mankind which is striving to bridge it.

As long as there was any possibility of improvement in the steam locomotive, man's inventive faculty concentrated itself there, and by every possible means endeavored to attain the theoretical point of economy with the aid of the agent, steam. But now the time is at hand when the limitations of steam have been fully recognized for all practical purposes. The limit has been reached. But the perfect application of steam still falls far short of the goal strived for; that is to say, the perfect machine is actuated by a force which has properties that do not admit of the highest economy. Man's inventive faculty, therefore, must turn to this new force which has properties that promise a greater economy in its application to motive power and strive to invent and perfect the machine which shall control and apply it. It seems just as certain that the perfect electric motor will be evolved from the present conditions as it is certain that the perfect steam motor has been evolved from the conditions which were present 50 years ago.

The first efforts to apply electricity are crude, just as the first efforts to apply steam were crude; the first electric motors are very imperfect, just as the first steam motors were very imperfect; but constant work on the problem will gradually evolve improvement after improvement, just as the steam motor was improved, until at last it has produced the mechanism which controls and applies the electric force to the full extent of its natural limitations. What those limitations are, we can only conjecture; they are no doubt much further in the future than the limitations of steam power were three-quarters of a century ago.

However, the almost certain knowledge that electricity will eventually supersede steam as a motive power on our railways need not disturb us in the least; it need cause not the slightest uneasiness to any existing interest, because it is absolutely certain that the supersession can only take place in conformity with well-defined laws of progress which must infallibly operate to adequate compensation for all apparent losses incurred during the period of transformation. It will merely represent a higher development of the means of transportation, and will have its analogy, so far as economic consequences to existing interests are concerned, in the change from the stage coach by the steam locomotive.

The 35,000 steam locomotives on our railways, representing a capital investment of at least $250,000,000, are not to be consigned to the scrap heap on an uncertainty, nor even in a hurry. Before the new power has the slightest chance to supersede the old, it must positively prove itself the economic superior of the old, and the demonstration of this economic superiority necessarily carries with it full compensation for all apparent losses that may be incurred.

We shall be compelled to meet these problems with our present resources as long as possible, and manipulate our present instruments for all they are worth, until their insufficiency has been absolutely demonstrated. When that time comes, there will be nothing left for us not to change to the new instruments and enter the field of competition on equal terms. It stands us in hand, then, to keep pace with the development in the science of electrical engineering, so as to be fully prepared to act intelligently on the changes that force themselves upon us, whenever it so happens that those changes are demonstrated to be unavoidable.

There was not much discussion on this, but what little was said appeared to indicate that a change from steam to electric traction was most probable but could not be a practical issue for very many years to come.

The report of the Committee on Transportation was read by Mr. Knibloe (Buff. Creek R. R.); it dealt mainly with the tonnage standard for loading freight trains, as a means of economy in freight service, and was substantially as follows:

Tonnage Rating of Freight Trains.

A circular was sent out containing interrogatories as to the methods of loading trains, whether by the tonnage system or by the car system. From over 200 members only 52 replies were received. Of the 52 roads represented, 22 were loading trains by the tonnage method, the balance were not. From the replies received from the members on whose road the tonnage system is in vogue, it is clearly shown that large savings can be made by use of the tonnage system. The percentage of increase shown in tons or cars per train by reason of the use of the tonnage system varies from 3% to 20%. The use of the tonnage system in five cases reported has served to increase the average speed of trains. In the other cases reported the speed has either decreased or no change has been noted. In a majority of answers it is shown that the tonnage system of loading trains gives greater uniformity of movement and avoidance of overloading of trains. Reports show that there is a large field for improvement in systematic effort tending to increase the number of tons of freight per car. One member reports that he has made an increase of from 12% to 15%, which is a remarkable showing. We therefore recommend that the tonnage system be used in loading trains in preference to the car system, and that the question of the loading of cars to full capacity is one that deserves close attention and will give very gratifying results.

In the discussion it was suggested that this was a case for the use of the dynamometer car to determine the actual efficiency. Mr. Brunn (Erie R. R.) said the tonnage system is giving excellent results on his road, one important result being that more empty cars are now available. Mr. Knibloe considered that additional track scales should be put in to facilitate the working of the tonnage system, while the length of trains should in any case be limited to that which the train crew can properly handle, regardless of loads.

In the afternoon there was an excursion to the power house of the Niagara Falls Power Co., after which another business meeting was held. At this meeting Mr. Derr (Erie R. R.) presented a very brief report from the Committee on Signaling, explaining that it had been thought preferable to invite some signal engineers to address the society. He therefore introduced Mr. Charles Hansel, Vice-President and General Manager of the National Switch & Signal Co., who delivered a most interesting address on the principles of signaling and interlocking, illustrated by an exhibt of the appliances used, and a complete set of instruments of the train-staff system of block working. In the explanation of the operation of these appliances he was assisted by Mr. Patenall, the inventor of the Patenall electro-mechanical slot. When Mr. Hansel had concluded his address, Mr. J. G. Schreuder, Chief Engineer of the Union Switch & Signal Co., exhibited a working model of an overlapping block signal system for single or double track lines, the signals being of the disk or "banjo" pattern. This system we shall describe and illustrate in another issue. The discussion was postponed until the following day, when Mr. Derr and Mr. Brunn explained the very complete system of absolute block working on the Erie R. R. Mr. Price (All. Vall. R. R.) has two yard sections fitted with the Union Switch & Signal Co.'s system above noted. Mr. Neville Priestly, of the Indian State Railways, said that on these railways there are signal and interlocking plants at the stations, but not to any extent on the open line, owing to the lightness of the traffic. We shall give a more complete report of this discussion in a later issue.

In the evening there was the annual banquet, which was a very enjoyable affair.

At the meeting on Sept. 10, the discussion on signaling was taken up, as already noted, after which there was a general discussion on the report of the special committee (presented at the meeting of 1895) on "The Relations Between Railways and Their Employees, Including Methods of Training and Discipline." In the afternoon there was an excursion down the Niagara Gorge Electric Ry. to Lewiston, on a special train, by invitation of Mr. J. M. Brinker, President of the railway. The party then crossed the river to Queenstown and returned on the Canadian side of the river by the Niagara Falls, River & Park Electric Ry.

CONVENTION OF THE ROADMASTERS' ASSOCIATION OF AMERICA.

The fourteenth annual convention was held at the Cataract House, Niagara Falls, N. Y., on Sept. 8, 9 and 10, with a fairly large number of members and guests in attendance, and an exceptionally large and comprehensive exhibit of track tools and appliances. The opening meeting was held Sept. 8, the President, Mr. C. E. Jones

(C., B & Q. R. R.) being in the chair, and the Vice-President, Mr. Kerwin (C. & N. W. Ry.), and the Secretary and Treasurer, Mr. J. B. Dickson (C. & N. W. Ry.) also present. The meeting was called to order at 11 a. m. Mr. Jones read a brief address, referring to the important work of the proper maintenance of the 180,000 miles of track in this country, and the proper handling of the army of men engaged in the work. The roadmaster should be able to instruct his subordinates in theory, and to lead and direct them in all practical work, especially in case of washouts, wrecks or other emergencies. He briefly referred to the aims of the association in bringing roadmasters in contact with each other, for the exchange of opinions and experiences, with the object of improving their efficiency and value to the railways. The association, he said, now has about 600 members.

Brief addresses were then made by some of the older members. Mr. Caffrey (L. V. R. R.) said that he never failed to get instruction at these meetings, and to go back with new interest and confidence in his work. He thought that the higher officers do not yet recognize the importance of the association and its work, and that it would be for the benefit of the railways if the officers insisted upon their men attending the conventions instead of merely giving them permission to attend when it is asked for. He also referred to the great increase in speed of trains which had been so noticeable within recent years, and which has in many cases been apparently made almost without consideration of the track conditions. Mr. Kerwin referred to the satisfactory condition of the finances of the association, and Mr. Collins made a few remarks as to the desirability of members present attending the meetings instead of sitting outside and discussing matters in a personal way. It may be noted here that there was very little interest shown in the discussions, though these are (or should be) the most important part of the proceedings. Perhaps if the reports were required to be sent in to the secretary in time to be distributed to the members a month or so before the meeting, the discussions might be more free, as the members would have had time to consider the reports.

The secretary, Mr. Dickson, then read his report for the year, showing the following results: Receipts for dues, fees and advertisements in the annual report, $1,941; expenses, $1,325; balance in bank, $615; amount still due to the association in payment for advertisements, $225. A vote of thanks was tendered to Mr. Dickson for the efficient manner in which he has transacted the business of the association. The list of applicants for membership was then read, and after their election the meeting adjourned.

The afternoon session commenced at 2.45 p. m., and the first business was the election of officers, which resulted as follows: President, R. Caffery, Lehigh Valley R. R.; First Vice-President, A. S. Weston, New York Central R. R.; Second Vice-President, T. Hickey, Michigan Central R. R.; Secretary and Treasurer, J. B. Dickson, Chicago & Northwestern Ry.; Member of Executive Committee (for a term of three years), Wm. Brandt, New York, New Haven & Hartford R. R.

The general business having been disposed of, the reports of committees were taken up, the first on the list being that on "Tie-Plates," an abstract of which is given in another column.

The discussion on this important subject was far from satisfactory, being mainly of a desultory and fragmentary character, in spite of the fact that nearly every man in the room had more or less experience with tie-plates, and in spite of the vigorous remarks of Mr. Jones and Mr. Kerwin, who rightly rebuked the members for this unreadiness. They meet mainly for the purpose of discussing practical questions, and if they do not discuss them a great proportion of the value of the convention is lost. As Mr. Jones said, if he were to talk to any one of these men when meeting him out on the track, they would give their own ideas and experience freely, and probably criticise the report in some way, while here they practically allowed it to pass by with only half-hearted consideration.

Mr. Collins said that in his experience tie-plates do hold the rails to gage, and he much preferred a plate with a shoulder the full width of the plate, as it puts a greater proportion of the resistance on the inner spike. He has had plates on 3° curves in main track, and 10° curves in branch track, laid five years ago, the rail braces being at the same time removed, and there has been no occasion to re-gage the track. It would be a wise economy to use tie-plates on all curves, and especially on switch leads, as ties and switch timbers wear by rail cutting and the adzing of the seat of the rail to set it back vertical. The use of a shoulder greatly reduces the wear or "necking" of the spike. A shoulder plate is preferable in any case, but he would insist upon it for use on curves. He was also strongly in favor of the use of tie-plates instead of rail braces. Mr. Hawkins (Nor. & So.) said his road uses cypress and white cedar ties, and next year it will complete the application of tie-plates to all ties. A great advantage in their use is the avoidance of continual re-gaging of the track. He was not inclined to believe in the necessity of using a shoulder on the plate, especially if the plate is properly punched to fit the spikes and rail. Mr. Dodson said that with oak ties it was not economy to use tie-plates on curves of less than 3°. He put plates on a 10° curve 18 months ago, and has had no trouble, while formerly using a brace on each tie, the track had to be re-gaged twice a month. Mr. Ross (Flint & P. M.) said that the use of the tie-plates increased the life of hemlock ties two years. He thought tie-plates better than rail braces, while the latter require three extra spikes to each brace, and the former requires no extra spikes.

Mr. Shanks (C. Vt.) said that in Massachusetts the life of a hemlock tie is about five years without plates and eight years with plates, but he would prefer a wider base to the rail instead of using tie-plates, since in his opinion this would give the same advantage at less cost.* He has used plates with and without a shoulder on top, and prefers the former. Mr. Greening (Lehigh Valley) said that in one case the rail necked the spikes so much as to widen the gage and nearly cut off the heads of the spikes. Mr. Dodson (So. Ry.) said that a shoulder added about 2 cts. to the cost of a plate, but he questioned the use of a shoulder, more particularly one 5 ins. long, or a shoulder on each side of the rail. With a rail brace, the cutting of the tie along the edge of the rail base throws the weight upon the head of the brace, tending to pull the spikes at the heel, while the tie-plate prevents this first cutting action. Other members spoke in favor of a shoulder tie-plate, with shoulder the full length of the plate, and Mr. Stickney (B. & Me.) said that he shimmed on top of such a plate. A vote was taken on the question of the advisability of using a shoulder or lip on the upper surface of the plate, and resulted as follows: 39 in favor of shoulder, 7 in favor of a flat plate. Several members, however, who use only the latter plates refrained from voting, and it should in fairness be pointed out that the flat-topped plate is the form used very much more extensively than the shoulder plates. On roads where track heaves, also, the shoulder might be somewhat of a trouble in shimming the track.

The meeting then adjourned. In the evening there was a very pleasant "parlor entertainment" at the hotel, consisting of songs, music and recitations, which was somewhat of a novelty and was very conducive to the more intimate acquaintanceship of the members and their friends.

At the morning session on Sept. 9, the first business was the election of Mr. J. A. Lahey (C. & N. P) as a member of the executive committee to fill the uncompleted term of Mr. G. W. Bishop, who has resigned on account of retiring from railway service. The report of the committee on "The Best Method of Protecting Facing Point Switches" was then read by the chairman, Mr. W. D. Otis (N. Y. Central):

Protecting Facing Point Switches.

The means of protection should be as follows: (1) A distant signal placed at least 2,000 ft. from the switch, depending upon the location; (2) A home signal located at the switch (with a positive indication in each direction to show whether the switch is set for the main or side track); (3) A facing lock which locks the switch. These should all be operated by a two-lever interlocking switchstand, so constructed that when the signals are put at danger it unlocks the switch so that it can be operated. The interlocking system should be so arranged that the danger signal cannot be put to indicate safety until the switch is again set for the main track.

The regular proceedings were then interrupted to hear brief addresses from Mr. John Doyle (Det., L. & N.), Past President, and Mr. I. Burnett, the founder of the association.

When the subject of the report was taken up for discussion, there was little desire to speak, and such discussion as there was had to be dragged out by the vigorous questioning of the chairman, who seemed unable, however, to arouse any particular interest in the matter. Mr. Weston said the plan recommended was that used on the New York Central R. R., for single track lines; 2,000 ft. is the least distance that it is safe to give an engineman to stop his train during foggy weather, and the signal cannot show "clear" unless the switch rail is fully home against the stock rail. The home signal at the switch is not a semaphore, but a double-lever switchstand with lamp and single target; it shows a red target and light when set for the siding, and no target and a white light when set for the main track. This is the practice on this road. Mr. Coates (N. Y., N. H. & H. R. R.) pointed out that this was in conflict with ordinary interlocking rules, by omitting the one signal, so that when set for main track there is a distant signal but no home signal. Mr. Doyle suggested putting on a white target or taking off the white light, so as to make the day and night signals the same. Mr. Shanks said that as a matter of fact different roads have distinct methods of practice, and it should be the duty of the association to endeavor to crystallize these into one uniform practice. There should be at every switch a red and a white signal. The absence of the latter tends to lead the engineman into carelessness in looking out for a red signal, while with a signal for either position his attention is attracted to the switch. As a result of the opinions expressed in this direction it was voted to amend the second recommendation in the report by the addition of the phrase given in parentheses. Mr. Coates said that there were other devices besides switch locks to effect the same purpose, including a yoke which must be thrown (first setting the distant signal) before the switch lever can be thrown. Mr. Reisler thought the report ought to be extended to include switches at block signals; on the Erie R. R. the switches and block signals are operated together without the use of an interlocking machine. Mr. Caffery, however, thought that the report was intended to refer only to switches operated directly by hand and not those at interlocking points. Mr. Reisler's motion was not carried.

Next in order came a paper on "Ditching," by Mr. J. M. Meade, Res. Engr., A. H. S. F. Ry. This was read by the secretary and received as information. The following is an abstract of this paper:

Ditching.

Whilst there is a general desire for action and information on this subject among all of us, it must be admitted that we have yet a great deal to learn, and this very ignorance is mainly due to a lack of teaching and training from those who know the real meaning or philosophy of the art.

As nearly every road has its own standards in regard to cross section and shape of road bed and ditching, it hardly seems necessary to attach to this paper plans showing how track should be ditched. It is an old subject. The main object is to remind the roadmasters of the great importance attached to this matter; economy in track maintenance begins right here, and one of the most important factors in prolonging the life of cross ties and saving the rails rests with good drainage. Good ditching shows for itself and tells its own story.

Our managers should never grumble or hesitate as to the security derived and money saved in allowing the roadmaster sufficient force to keep his track well drained. One or two days' rain will often spoil weeks and months of hard work by the section foreman by neglect of this kind.

In ballasting or other important track work, great attention should be given to the matter of drainage; every ditch should be amply large to carry off all the water that will ever come into it and sufficiently deep to keep the moisture away from the ties and ballast. Frequently on new roads, cuts will slide in and sometimes make the track impassable; this is often prevented by a good surface ditch on top, placed some distance back from the top edge of the cut, as circumstances will admit. In cases where this will not stop the sliding, the writer has known bad cases cured by cutting vertical trenches on the slope of the cuts from top to bottom, placed about 20 ft. apart, as the case demands, with the dirt mounded up in oval shape between the trenches. This is a good remedy where the earth seems to be alive and constantly on the move.

Many roadmasters seem to think that it is not necessary to spend any money draining banks. This is a mistake; banks should be properly drained as well as cuts. Rough track is often found on embankments caused by the ties being buried in mud. This is wrong; ties on embankments should have free drainage from their ends, on a slope of at least over 1 in. in 12 ins. We often meet with material in cuts of a spongy or boggy nature, where even rock ballast will not keep the track smooth. I have seen bad cases of this kind cured by putting porous tiling in the side ditches and cinder ballast at least 12 ins. deep under the ties. Where places of this kind are encountered in cuts there is no end to the trouble and if the grade of the railway can be changed to at least 0.5% it will often give permanent relief.

We often hear the question raised: "How much of the time of a section gang should be given to ditching?" This can best be answered by the circumstances governing the case. In the proper seasons for this kind of work, and where sufficient help is allowed, it is considered good practice to give at least one-fourth of the time to the matter of ditching.

The next report was that of the committee on superelevation on curves and the use of easement curves; this was amended somewhat during the discussion and the following is the report substantially as adopted:

Superelevation on Curves for Speeds of 10 to 70 Miles Per Hour, and the Advisability of Using Easement Curves.

We are of the opinion that curves should be elevated for the highest speed at which passenger trains usually run over them, limited, however, to an elevation of about 7 ins. if the track also carries freight traffic. If exclusively passenger traffic we would not be limited to 7 ins. if the circumstances seemed to require more.

We recognize the various conditions that may require a modification of this rule. In such cases each will be governed by the prevailing circumstances, bearing in mind that the passenger traffic deserves more consideration than freight.

At the proper speed for which the curve is elevated each rail carries equal weight; in other words, a weighted line through the center of gravity of the car will remain perpendicular to the plane of the rails while passing the curve.

When trains pass curves at greater speeds than the track is elevated for, the weight on the outer rail is increased, flange friction is increased and the tendency to turn the outer rail over is much greater, but we believe in full elevation because it is not only safer but a much better riding track and the advance in the condition of track and increased average speed require greater attention to this matter.

We are decidedly in favor of easements for all curves of 2° or over. They make the entrance to curves gradual, reduce the shock at high speed and keep the line much better. They should be put in with a transit and should be of sufficient length to carry all the elevation at the rate of about 50 ft. per in. That is, the elevation should begin with the easement and reach full elevation at beginning of regular curve. The spiral or cubic parabola is equally good.

Where no easement curves are used we recommend full elevation at ends of curves, running it out on tangents at the rate of 50 ft. per in., except for reverse curves. Uniform elevation, good line, gage and surface are as essential as the proper elevation for a perfect track.

---

*It is hardly necessary to point out that this is an entirely erroneous idea. Such a distribution of metal in a rail would be very bad, and the added metal would add but little strength to the rail, while that part lying between the ties would be so much wasted metal. It is far better practice to slightly reduce the width of the rail base with a view to the use of tie-plates, as in the Dudley type of rail sections, where the width is slightly less than the height.

Where easement curves are not put in by the engineer, good results can be obtained by throwing in the whole curve a given distance and flattening the ends by extending the curve beyond the ends of the original curve equal to one-half the length of easement. To get easement of a certain length as the curvature increases, the amount the original curves move in will increase.

Your committee recommends the use of the formula in mechanic's text books, viz.:

$$\text{Elevation} = \frac{G \times V^2}{32.2 \times R} \text{ in which}$$

G = gage of track in feet,
V = velocity of train, in feet per second, and
R = radius of curve in feet.

The following table computed by this formula shows the elevation in inches for each curve, 1 to 10°, and for speeds of 10 to 70 miles per hour, inclusive:

Deg. of	Miles per hour							
curve.	10.	20.	30.	40.	50.	60.	70.	Remarks.
1	1-16	¼	⅝	1	1⅜	2⅛	3	Maximum elevation about 7 ins. by the formula given.
2	⅛	½	1¼	2	2¾	3¾	5	
3	3-16	¾	1⅞	3	4⅛	5½	7	
4	¼	1	2½	4	5½	7	..	
5	5-16	1¼	3⅛	5	6⅞	...	..	
6	⅜	1½	3¾	6	8⅛	...	..	
7	7-16	1¾	4⅜	7	...	...	..	
8	½	2	5	8	...	...	..	
9	9-16	2¼	5⅝	9	...	...	..	
10	⅝	2½	6¼	10	...	...	..	

Mr. Doyle explained that it was not thought necessary to work out the elevation for the high speeds on the sharp curves, since in operation the trains would be slowed down on such curves. Mr. Coates (N. Y., N. H. & H. R. R.) said he preferred a formula giving a higher rate of elevation on a high degree curve than on one of low degree. Thus for curves of 1°, 2°, 3° and 4°, he would give (for 40 miles per hour) an elevation of 1½, 2⅜, 3⅛ and 4 ins., instead of the 1, 2, 3, 4 ins. given by the committee. He would also limit the elevation to 6½ ins. The Pennsylvania R. R. uses a cord 75 ft. long, stretched on the gage side of the outer rail, the middle ordinate being equal to the elevation. Taking a case where passenger trains run down grade at 60 miles per hour, and freight trains go up the grade at 15 miles per hour, should the elevation be calculated for the fast or the slow train, as the high elevation necessary for the former will seriously affect the operation of the latter. Mr. Stimson (G. R. & I.) said that under such conditions on his road the curves are put up for the fast trains, though the freight trains wear the inside rails pretty badly, but the management requires this to be done for the safety of the fast trains. Most of those participating in the discussion approved of the use of easement curves, though some members did not appear to be clear as to the purpose or laying out of such curves. Mr. Emery thought there are places where such curves cannot be put in on existing roads, as, for instance, where the curve ends at a bridge or tunnel, or in a narrow cut with masonry retaining walls, or where curves come very close together, while the method of flattening the ends and sharpening the centers of curves would necessitate an entire realinement and the purchase of additional right of way in some cases.

In the afternoon there was an excursion on the Niagara Falls, River & Park Electric Ry. (on the Canadian side of the river). At the evening session the report of the committee on "The Latest Improvements in Frogs and Switches" was taken up, but it did not in any way follow the ground indicated by the title, since it was merely a general sort of report on frogs and switches, reiterating recommendations which are now pretty familiar. An abstract of this report is given below:

Frogs and Switches

It is very essential that all roads should adopt some form of frog and switch as a standard, for use at all places except where some special design of construction is necessary. Where railways do not manufacture their own frogs, switches and crossings, it is well to furnish frog makers with a complete set of their standard blue prints and specifications for same, but in the event of special frogs, etc., careful measurements should be taken and blue prints furnished accordingly.

For main line work, spring rail frogs not less than 15 ft. long; and in yard work, wherever practicable, spring rail frogs of not over 12 ft. in length. Variations from this, of course, depend greatly upon the circumstances under which the work is to be laid out. Where a rigid frog is adopted for such work with a heavy traffic, a bolted and filled frog with ¾-in. steel plates is certainly preferable and more economical. A great deal depends, however, as to the kind of frog to be used, which can only be determined upon under the existing circumstances.

The clamp frog may be utilized to advantage in main line service where traffic is light; the great objection, however, to this class of frog is its inability to support itself; the clamps naturally become loose, in consequence of which the wing rails receive the weight of passing traffic, the point dropping below the surface of the wing rails, causing them, sooner or later, to become battered and useless. The only advantage gained in the use of the clamp frog is that when one wing rail is worn it admits of the frog being transposed, or having a new wing rail substituted at a small cost, thus prolonging the life of the frog. In complicated yards where a large number of switches and frogs are necessary this style of frog cannot be used to good advantage on account of the long ties, as the clamps project below the base of the frog, requiring a greater spacing of the ties or shorter ones used; whereas a frog with a plate can be used under any conditions. In yard work where sharp curves are necessary, a frog 12 ft. long is recommended, owing to the fact that frogs placed in curves of low radius require a wider throat and flangeway, consequently the space from outside of guard rail to point is greater in order to allow the wheel flange to pass through without binding, overcoming the battering and pounding down of the entire frog. The clamp frog, for the time being, gives but little trouble, having no bolts and rivets to become loose, but is on the whole a very expensive frog as a result of its loose method of construction, there being no support whatever to the point. On the other hand, the bolted frog with ¾-in. steel plates, made in proportion to the size of the frog, has a tendency to support it equally through its entire area of bearing and is certainly the most economical.

While spring rail frogs in yard construction may or may not be as economical as the bolted and filled frog, it is not good policy to make a general use of them in freight yards where a great amount of switching is required, as switchmen are more or less liable to have their feet caught in the frog. The objection to the double rigid frog, as usually made, is that the wheels are furnished with no guard in passing from one point to the other. In order to overcome this difficulty it is well to have the guard rail of the frog so made that it will shade both points ⅛-in.; in this manner one frog will answer as a guard for the opposite frog while trains are passing through the combination. Rigid double frogs up to No. 7 can be used on combinations of 8° 10′. In combination switches above this the use of movable point frogs is recommended.

In a proposed guard rail two clamps are made use of on either end which hold the rail rigid and overcome the possibility of the rail turning over. The two bends in either end have a tendency to crowd the wheels gradually through the frog, preventing them from striking the point, reducing to a minimum that sudden shock which would otherwise be the result in the use of an ordinary guard rail. For main line passing tracks a No. 11 spring frog is recommended. For yards and miscellaneous sidings it is impracticable to adopt a standard frog as all depends upon the location and amount of room at disposal.

Since the adoption of the interlocking system at railway crossings, allowing trains to pass at full speed, the expense is consequently materially increased, as they require a greater amount of care and attention. Thorough inspection should be made each day of such high speed crossings, and any defects at once remedied. Roadmasters must endeavor to keep them in such shape as to avoid the complaints which might otherwise arise from other roads with which their line intersects, reducing the cost of maintenance to a minimum, and in order to do this they should receive constant care from the time they are placed in position. A crossing should be placed in such a manner as to be perfectly rigid, and the least expense will be incurred in the maintenance of such a crossing. In order to accomplish this it is advisable, if the circumstances will admit, to have at least 4 ft. of broken stone foundation, with framed timbers of suitable kind and size, and a properly-constructed drain from the bottom of the pit. The gage of crossings on tangent should be 4 ft. 8½ ins., with 1¾-in. flangeways, placed on ¾-in. steel plates, made in proportion to the angle and area of the crossing.

On one complicated crossing the flangeway on the inside of the curve is 2¼ ins., and on the outside 2⅜ ins. The flangeway is necessarily made narrow on the inside so as to answer for a guard rail and wider on the outside to allow the necessary space for curvature of the wheels.

Switches in main tracks should be put in with a theoretical lead corresponding with the theoretical switch point, in accordance with the angle of the frog, and where a 15-ft. switch point is used, as is very often the case, the length of the lead should be shortened the difference between the theoretical switch point and the 15-ft. point, which will make the lead practicable. Where a 15-ft. switch point is used as a standard for yard work the leads can be shortened; for instance, a No. 15 frog can be used on any lead from 115 to 132 ft. No. 10 frogs are often used as a standard in connection with a No. 9 lead. Then why not use a No. 9 frog with a lead to correspond, as it certainly would be practicable, furnishing as it does a perfect curve in making use of a frog one size less and would last longer than a No. 10 if a rigid frog?

All switches should have a 5-in. throw, as they are more economical to keep in repair and also do away with that element of danger caused by wheels catching the open point, which is often the experience with switches having less throw. It is very essential to have a suitable guard rail placed 4 ft. 6⅝ ins. from the point of the frog, regardless of the gage of the track, as oftentimes tracks leading to factories, etc., are gaged to 4 ft. 9½ ins. Two tie rods on all yard switches are also recommended, with a stop block on the stop rail; the stock rail should be bent 9 ins. ahead of the point and the switch point will set up snug and in perfect shape as far back as the point is planed. A kink in the stock rail ahead of the point all the way from 15 to 20 ins., is often made use of. The objection, however, to this method of construction is that it permits worn or double flanged wheels to run in the space between the point and the stock rail as the only part of the point that sets up against the stock rail is just near the point of the switch. All main track switches should be made with reinforcement bars connected to the points, in order to hold them securely in position should they become broken, and thereby prevent in many instances a serious derailment.

At the morning meeting on Sept. 10, the first subject taken up was Rail Joints. The committee had made no report, but the chairman thought the matter important enough to be discussed even though the committee had neglected its duty.

Rail Joints.

Mr. Brown approved a suspended joint with ties 12 to 15 ins. c. to c., but with the addition of a base support; he has tried the Long and Thompson joint. Mr. Stickney has been using the Weber and Continuous joints, and his foremen claim that the latter is the easier to maintain. Mr. Black (Manhattan Elevated) said that seven years ago his road adopted the Samson angle bar on a 70-lb. rail, but after about two years' service this would break in the web. They then tried a truss joint, and then the Weber joint, which is now the standard and is applied to 90-lb. rails. Some of the Weber joints were put on old rails which had been in use nine years and were ready to be taken out. The rails improved so much at the ends that they remained in four years more. Mr. Coates said that the Weber joint is used on the four-tracks of the New York, New Haven & Hartford R. R., leading out of New York; careful measurements of the four joints which had the Weber joint applied on April 25, 1893, showed the following deflections:

	April 24, 1893. in.	May 1, 1893. in.	May 9, 1893. in.	April 14, 1896. in.
Joint No. 1	5-64	2-64	1-64	0
" No. 2	5-64	2-64	2-64	0
" No. 3	6-64	3-64	2-64	0
" No. 4	4-64	2-64	1-64	1-64

Mr. Hickey (Mich. Cent.) said that many of the 44-in. iron splice bars were taken out, straightened and put back, but the 44-in. steel bars did not give any trouble by bending. Mr. Shanks has had good results with Weber joints on new 75-lb. rails, and by putting the Continuous joints on old 60-lb. rails which had had 16 years' service, he brought the rail ends back into tolerably good surface; he approved of a suspended joint with bridge or base support. Mr. Ware (B. R. & P.) had put Weber joints on rails that had got badly pounded by 13 years' service, and brought the rails back to better condition. Mr. Sullivan (Boston & Albany) applied 12 Continuous joints six years ago; two of these were recently taken off, but a straight edge placed on the rails and on the splice bars showed no deflection. Mr. Caffery (L. V.) evaded the usual inquiry about miter joints by saying that the discussion referred to joint devices, while the miter-cut rail ends could be spliced by any form of joint device.

The next and last report was that of the Committee on Ballast, which was substantially as follows:

Ballast.

1. What is the best kind of ballast?

Stone.—Ballast made from stone, crushed to the proper size for tamping, that will neither solidify in track, nor disintegrate while being worked, makes the best ballast.

Gravel.—The term gravel, as ordinarily used, applies to so many different kinds of material that, in alluding to it, an explanation should follow each statement describing the quality of the gravel in question. We have seen gravel in small quantities, generally in pockets, that was clean, hard stone; ranging in sizes from that of a pea to a hulled walnut. No material could be better for ballast than this, but, owing to the amount of soil and fine sand that is usually put in track with the gravel, we find it inferior to crushed stone.*

Burned Clay.—This has many qualities to recommend it for ballast, and those who have used it the longest are the most enthusiastic in its praise.

Furnace Slag.—This makes very good ballast, and the same may be said of locomotive cinders under certain conditions.

2. What are the best methods for handling different kinds of ballast?

The methods of handling ballast differ under different conditions and localities. What would be economical in one case, would be expensive in another.

Stone is generally moved from the quarry to the crusher by small dump cars on an inclined railway, attached to cables. Where it is convenient to locate the crusher about level with the quarry, parties who move the stone with dump carts claim that they can do it more economically than with cars. After the stone is crushed, it is elevated and put into storage bins, convenient to load into cars by gravity. The distribution of crushed stone on track can best be done with hopper bottom cars. The Rodger ballast car is, perhaps, the most complete car for this work that is in general use.

Gravel can generally be more economically loaded with steam shovel than in any other manner. It can best be handled in hopper bottom cars also, or may be distributed with good success on flat cars, when the haul is not too long, and unloaded with the rapid unloader. Furnace slag and locomotive cinders may be handled the same as gravel.

3. What is the best kind of cross-section for each kind of ballast, both as to roadbed and ballast?

The best cross-section is the one which will keep the destructive elements farthest from the track. Roadbeds should be wide enough to reduce the heaving of the track to a minimum.

They should be drained below the frost line in all clay cuts. Where it cannot be done by open ditches, it may be successfully done with tiling. Whether drainage is made in open ditches or under ground, it should be done with the view of getting the water away from the track as quickly as possible.

In the discussion on this report, Mr. Caffery said he thought ¾-in. stone too small, and would prefer it 1½ to 2 ins. in size, as with this limit there would be plenty of the smaller sizes to fill in. Mr. Coates had tried 2½-in. stone, but found it too large, the stones from the crusher coming out in long narrow pieces, so that a stone of 2½-in. section is entirely too large; he favored breaking to a 1½-in. ring, and thought ¾-in. so small that in tamping the stones would be crushed and broken. He has used trap, limestone and sandstone, the latter being very unsatisfactory, as might be expected, as it breaks in tamping and gradually crushes. Mr. Mott laid one mile of ¾-in. stone screened from dust and dirt, which made excellent ballast, but he would prefer 1½-in. stone similarly cleaned. Mr. Lahey considered it the best practice to use a bottom layer of coarse stone and a top layer of screenings. Mr. Brown thought there were as many varieties of stone as of gravel ballast. If stone is crushed fine it disintegrates so rapidly that it is expensive, and he therefore uses a 3-in. ring. With light rails on coarse stone ballast, however, it is difficult to keep the rail in good surface, as the stones cut into the tie and make an uneven bearing. Mr. C. E. Jones (C., B. & Q.) said that in 1880 his road accepted the proposition of Mr. Davey, of Chicago, to burn 10,000 cu. yds. of clay for ballast, and now the road has hundreds of miles so ballasted, 58 miles being on his own division. Gumbo (not clay) makes the best material for burning as it has more combustible matter than clay, and comes out in pieces about the size of a walnut, though some clay makes good ballast. Even good stone ballast will crush under bad rails, and burned clay has been criticised because it has failed under similar conditions, but if properly burned and properly laid under good rails it is an excellent material. On newly ballasted track, the burned clay is laid about 8 ins. deep under the ties. At first it cost about 90 cts. per cu. yd. at the pits, but now it costs only about 19½ cts., the company furnishing the ground, coal and tracks. One ton of coal will burn about 5 cu. yds. of ballast. Slack coal is used with a little hard coal to help the fires, but wood will not answer the purpose. There must be an experienced man in charge to attend to the burning. Contrary to the claims of contractors welds will grow in this ballast. As to the handling of ballast, several members spoke in favor of the Rodgers' ballast car.

---

*Reference might have been made here to the practice of washing gravel for ballast.—Ed.

A motion to reopen the discussion on tie-plates was suggested by Mr. Emery, but it was eventually decided to take up the subject again at the next annual meeting. After the passing of various resolutions of thanks, etc., the meeting adjourned. In the afternoon there was an excursion to the power house of the Niagara Falls Power Co., and a dinner was given at the hotel in the evening. On Sept. 11 there was an excursion by rail to Lewiston, and thence by boat to Toronto, and a very large number of members participated in this trip. The next meeting will be held at Old Point Comfort, Va., on the second Tuesday of September, 1897.

There was a large and representative exhibit of track materials and appliances, arranged by the Road and Track Supply Association, of which Mr. H. W. Frost is Secretary, and a general statement of these exhibits will be found in our Supplement this week.

CONVENTION OF THE STREET RAILWAY ASSOCIATION OF THE STATE OF NEW YORK.

The fourteenth annual meeting of the Street Railway Association of the State of New York was held at the Bennett House, Binghamton, N. Y., on Sept. 8, with President G. Tracy Rogers in the chair, and 33 delegates of street railway companies and about 60 other attendants present. President Rogers delivered an interesting address.

The executive committee made its report, laying special stress upon the importance of carefully watching bills presented to the State Legislature affecting the physical and financial operation of street railways. In the last session 140 bills and amendments of this character were presented. In view of the increased attendance and volume of business to be transacted the committee recommends that hereafter two days shall be devoted to this annual convention. The report of the Treasurer showed, for the year, receipts of $6,997.86, and an expenditure of $6,700.88. The reading of reports was then taken up and Mr. G. H. Stedman, of Rochester, N. Y., presented the first, upon "The Matter of Transfers." He believed that a liberal transfer system, properly guarded to prevent fraud, pays; and, within certain limits, the more frequent the transfer points, the better. The weight of opinion now seems to favor the "ringing up" of transfers as well as cash or pass coupons. In the debate which followed Mr. Rossiter, of Brooklyn, said that in August his company transported 2,600,000 passengers on free transfers, and increased earnings $40,000. He ascribed the gain to a liberal system of transfers, as his company gives a transfer to a passenger riding on a transfer; though he doubts if 2% of the passengers demand the second one. Mr. Deming, of Buffalo, complained of the abuse of transfers in his city, stating that the system there was so laid out that it is possible to ride all day long on a transfer. Some more complicated system of tickets with the names of streets printed upon them may remedy the matter, but he was not sure. Mr. Robinson said that there were lines in New York city upon which five or six transfers could be secured; the passengers give these tickets to boys who sell them, and trouble results. The travel is too great to permit the use of punched tickets. Investigation, however, shows that the illegitimate use of tickets is not great. On lines in the retail dry-goods districts transfers cause a large increase in travel. To a question of the percentage of transfers as compared with cash fares, delegates answered as follows: In Syracuse, 25% of the passengers were carried on transfers; Buffalo, about 32%; Binghamton, a little less than 25%; Rochester, 27 to 30%; Brooklyn, 22 to 25% in summer, and 16 to 20% in winter; on the Atlantic Avenue Line in Brooklyn, 16% was the average for nine months in the year.

Mr. C. Loomis Allen, of Syracuse, read a paper on "General Track Construction, and the Most Approved Method," advocating especially the use of a harder quality of steel in the rails than was generally furnished. He said that none of the high-carbon rails on the New York Central Railway, near Spuyten Duyvil, have broken after six years of unusually heavy traffic, though the makers saw fit to warn the railway company that they would not be responsible for any damage resulting from the use of what they considered unfit material. Mr. Allen quoted "a firm of steel inspectors" to the effect that high-carbon rails would give from 40 to 60% longer life than rails of ordinary Bessemer steel. To-day, these rails cost no more than ordinary steel rails. In Syracuse rails are being now laid 60 ft. long, 9 ins. high and of the half-groove section. The joint is the ribbed or corrugated 12-bolt, 36-in. joint. Mr. Rossiter said that his company used practically the same rail, but in 30-ft. lengths, and few rails break in handling and the wearing results are more satisfactory than with the old rail. The President closed the discussion by saying that he did not know of many roads adopting the high-carbon standard.

Mr. W. W. Cole, of Elmira, presented the next paper entitled, "How Can We Prevent Accidents and Increase the General Efficiency of Employees." He regarded the proper selection of employees as the first and most important requisite, and he submitted a series of questions put to all new men, the most important of which were as follows: Relating to the ownership of real estate or personal property; to personal debt; the use of intoxicants; the highest wages previously received anywhere. Mr. Cole recommended that all employees should be placed under a bond of at least $200, as this had a restraining influence upon the men and also upon business men recommending men to the company. After a man has been turned in as competent by his instructor, he should pass an examination as to his duties and the regulations of the company. All motormen should be furnished with blank reports to be filled out each evening and giving the condition of his car, and file this report with the foreman of the shops. If trouble with any part is reported, an inspection should at once be made, the report signed by the inspector and sent to the superintendent. Such a system is more efficient than mere verbal reports. Thorough shop inspection is another important preventative of accidents; and this demands a system of reports in all departments that will form a connected chain and check the work of the individual, provided that the system is not complicated and is always attended to. Loss of power is a frequent cause of accident, and no road should try, from an economical point of view, to run too close to a theoretical consumption of power. There are too many contingencies which theory will not meet. Mr. Robinson described the system of instruction in use on the Metropolitan Street Railway. His company has organized a club in one of the depots where a series of lectures are given every two or three weeks, illustrating by stereopticon views the underground trolley, cable machinery and apparatus and the general operation of the road. He considered individual instruction preferable, but stated that the lectures were largely attended and were advantageous. Mr. Rossiter's company depended entirely upon instructors to teach the men the running of the motors, and the superintendent was supposed to instruct the men in the details of each division, grade crossings, stops, etc. Out of 1,600 men employed in August only 16 motormen left the service of the company in that month, showing that the men took an interest in their work. Mr. Fitch, of the Erie Railway, and Mr. C. D. Hammond, of the Delaware & Hudson Canal Company, both approved of the thorough examination of all employees, with schools of instruction.

Mr. H. S. Newton then read a paper upon "Power from the Trolley Circuit." He advocated the sale of surplus power to manufacturers as the only way of reducing loss from idle machinery. In New York State this method of disposal is attended with many difficulties owing to the restrictions put upon it by the insurance people. He illustrated the advantages possessed by the railway companies, as producers of power for private consumption, as follows:

> Take for example a station in one of our cities containing a 1,200-HP. direct-coupled Corliss engine held in reserve, and estimate what could be done with this engine and its attached generator were it thrown into active duty on a private consumer's power circuit. Figure on an investmentment of $75,000 in the engine, generator, and other apparatus relating to the two. Then assuming coal to be worth $3 a ton and the engine to have a fuel duty of 3 lbs. per HP. per hour, we have coal consumed for each day of ten hours:

18 tons, at $3	$54
Cost of labor, engineer, firemen and oiler, say	10
Oil and waste	2
Incidental repairs	10
	$76
Add to this 10% depreciation for one day	21
And interest on the investment at 5%	10
	$107

> Then figuring on an ability to sell the output for ten hours in the day at 2¾ cts. per 1,000 Watt-hours, we have 1,200 HP. for ten hours equals 8,952,000 Watt-hours, at 2¾ cts., equals $246. With cost of production as above stated, the net profit amounts to $139.36, a fair sum to go towards reducing operating expenses.

Mr. Newton believed the purchase of this power would not only be profitable to the users of the smallest unit, but also to those using 50 to 100 HP. steam plants and employing their own engineers. At 2¾ cts. per 1,000 Watt-hours, the charge would be but little over $10 per day for the equivalent of 50 HP. used uninterruptedly. The presumption is that the small engine and boiler employed to move line-shafting, with the increased power necessitated by loss in friction would more than overbalance the bill sent in for electric power. The objections of the insurance companies or Board of Fire Underwriters, seem to be embraced in the one feature of ground return. They suggest that you build a fireproof house, outside the shop, for holding the motor and run the machinery inside by a belt and line-shafting. If this is not done the insurance rate is increased 2%, because the Underwriters claim that no reliable method of insulation has yet been discovered that will make the installation a good risk. Mr. Newton said that in Syracuse there were 400 or 500 iron poles, each pair of which was a dead ground to the trolley wire suspended between them. Yet in three years there has been no ground on these poles. He admits that many disastrous fires have been started by defective installation; but he contended that a large percentage of these resulted from the contact of a current-carrying wire with water or gas-pipes; and that 90% of the arc-light circuits, if subjected to the gas-pipe test, would show as great a capacity for kindling fires as the trolley circuit. Yet these arc circuits, with 3,000 to 5,000 volts difference of potential and their invariably grounded circuits come into any building. He believed that with protected wiring and reliable insulators, both systems could be made absolutely safe.

Mr. James B. Cahoon next read a paper on the "Daily Inspection and Care of Car Equipment." He advocated a rigid daily inspection of motors, trucks and car-bodies by competent inspectors, and enters into the detailed processes of this inspection. Mr. H. S. Cooper, of Schenectady, presented a paper on "The Desirability of Forming a Board of Claim Agents," the subject matter of which was referred to the executive committee.

In the afternoon session Mr. F. O. Rusling, of Rochester, introduced "The Use of Old Rails as Underground Conductors." Mr. Rusling, while Superintendent of the Buffalo Railway Company, called in expert advice to remedy serious indications of electrolysis of pipes within a half-mile of the power house. The pipe system affected and surveyed included three systems of natural gas pipes two of illuminating gas, one of water pipe and two conduits. The large copper cables already connected were found to be entirely inadequate. The danger points lay, one 1,500 ft. north and the other 1,800 ft. east of the power house, with deliveries of 1,000 and 3,000 amperes respectively. To bring this current to the power-house with only 5 volts loss, would have required the use of $8,000 worth of copper. In this emergency the expert recommended the use of some old tram-rails on hand, worn down to 50 lbs. per yard, high in carbon and brittle. Their conductivity was tested to 1,500 amperes, and finally four rails laid parallel were tried on the 1,500 ft. length. Mr. Rusling describes the connection of these rails as follows:

> The rails were bolted in pairs back to back and arranged so that the end of one rail was at the center of its mate. The bonding was effected by scraping contact spots with a file near the end of each rail and amalgamating them with the Edison solid alloy. A steel washer, ¼-in. thick, 1⅓ in. inside diameter and 4 ins. outside, was dipped into hot insulating compound and placed against one rail so as to enclose the contact spot. The hole in the washer was then filled with the Edison-Brown plastic alloy, inclosing an amalgamated steel spiral spring. The upper rail was then bolted on and the completed conductor lowered to the bottom of a wooden trough, resting on one edge so that gravity would maintain the contacts. It will be evident that with this arrangement, two of the bonds on any one rail would have to give way before the circuit could be broken; each bond was made sufficient to transmit 1,500 amperes. When the second set of rails was lowered into place, the trough was filled with a hot insulating compound and a cover nailed down. This compound was cheaper and better than asphaltum; it remains viscous even in cold weather and has high insulating qualities. It is a product of petroleum distillation much lighter than asphaltum and costing about $25 per ton.

This four-rail conduit carried at heavy load 1,100 amperes 1,500 ft. with a loss of 4 volts, as ascertained by repeated and careful testing. A copper insulation would have weighed 20,532 lbs. and cost $2,462.83; the rail lengths weighed 50 tons and cost as scrap but $400. The steel resistance, with 50 bonds in each length, was about 5.63 to 1. The 1,800 ft. length was then treated by laying a 14-rail conduit, with some improvements in the method of assembling them. When tested the performance was again satisfactory, as the 14 rails transmitted 3,250 amperes 1,800 ft. with but 4 volts loss. The rails used weighed 210 tons, and, at $8 per ton, cost $1,680. A copper installation would have cost $10,389 for the same work. The total cost of both rail conduits was $3,322, as compared with $12,852 for equivalent copper. Mr. Rusling does not advise the use of buried rails if copper is used for connections, as it is impossible to get the full conductivity of the rails and the copper oxides rapidly in many soils. There was no discussion on this paper.

The next paper considered was on "Railway Power Stations," presented by Mr. Thomas Henning, of Buffalo, dealing generally with the points to be observed in managing a power station. Mr. W. G. Clark, of New York, then addressed the meeting upon the general subject of "Electrical Development." The convention voted to hold the next annual meeting at Niagara Falls, on the second Tuesday in September, 1897, and to devote two days to it. The officers elected for the ensuing year were: President, G. Tracy Rogers; First Vice-President, W. Caryl Ely; Second Vice-President, John H. Beckley; Executive Committee, H. H. Vreeland, John W. McNamara, Henry M. Watson, C. L. Rossiter; Secretary and Treasurer, H. A. Robinson. The convention closed with a banquet in the evening.

THE BROOKLYN WATER SUPPLY has recently been the subject of complaint on account of objectionable taste and odor. A report by Prof. A. R. Leeds, of Stevens' Institute, states that the taste and odor are due to the decomposition of vegetable organisms in the water; which though objectionable are not harmful or dangerous. Mr. I. M. De Varona, Chief Engineer of the Brooklyn Water-Works, in transmitting Mr. Leeds' report, calls attention to the need of laboratories equipped for systematic chemical and biological examinations of the water supply. He has recommended the establishment of such laboratories in his last two annual reports, and believes that the present trouble could have been avoided had such laboratories been in operation. The widespread complaints respecting the quality of the water, however, have resulted in appropriations for needed work in the water department. On Sept. 18 the aldermen appropriated $150,000 for diverting Horse Brook, a polluted stream, which now enters one of the reservoirs, $75,000 for buying and cleaning ponds not now owned by the city, and $311,555 for current expenses, included in which is $45,000 for cleaning ponds and reservoirs now owned by the city.

We note that in the debate over appropriations one of the aldermen expressed his conviction that some of the bad taste of the water was due "to the effect on the water mains of waste electricity from the trolley wires!"

◆

MILWAUKEE'S WATER SUPPLY has been assailed as to its quality by Dr. Kemster, the City Health Commissioner, who declared in a report dated Sept. 12 that the water had been contaminated by sewage from the city and by the dumping of garbage into the lake. Analyses of the water, however, by Prof. Victor C. Vaughn, of the Michigan University; Prof. E. G, Smith, of Beloit College, and A. S. Mitchell, State Chemist of Wisconsin, all show that the water is pure and wholesome.

◆

THE WATER SUPPLY TO JERSEY CITY, which has been furnished by the East Jersey Water Co. since April 12, is now the subject of controversy as respects payment. The company claims that the city is bound to pay for all the water it has received the full price of $43 per million gallons. The city officials hold that as the company did not furnish the full supply on April 12, which it agreed to furnish, the city is not bound to pay the full contract price per million gallons for the partial supply it has received.. It has not been able to shut down its Belleville pumping station as it would have done had the full supply been furnished, and as it has not been able to make this saving it should not be compelled to pay the full price for the partial supply.

◆

IMPURITIES IN CHICAGO'S WATER SUPPLY are claimed to have caused the death of over 3,000 infants and young children during the past twelve months. The Chicago Health Department has made a careful study of the subject of infant mortality and has concluded that the efforts which the department has made to secure a pure milk supply will avail little to secure a decrease in infant mortality till the quality of the water supply is improved. The Chicago "Record" quotes as follows from the department's report for August:

> It is not unreasonable to infer that if the Chicago water supply had been as good during the last twelve months as the Chicago milk supply, the death of infants and young children, instead of aggregating nearly 10,000 during the period, would not exceed two-thirds that number, which implies an avoidable loss of more than 3,000 lives in this age period alone.

Besides infantile diseases, typhoid is increasing of late. In the first 21 days of September there were 64 deaths from this disease; and there are said to be over 600 cases in the city.

◆

WATER METERS have scored a great success in Atlantic City this year. At the beginning of the year about 350 were in use. The city appropriated $25,000 for the purchase of additional meters, and 1,520 additional meters have been put in service since that time, so that 70 of the consumers now take water through meters. The result has been a decrease in water consumption of nearly 20%, the average daily consumption for August, 1896, having been 6,285,460 gallons, against 7,726,000 gallons in August, 1895. The laying of an additional supply main across the meadows, which was deemed necessary some time ago, has been indefinitely postponed by the decreased consumption due to the use of meters.

◆

BIDS FOR SIX LARGE PUMPING ENGINES are asked in our advertising columns by the city of Chicago. Each engine will be of the vertical condensing triple-expansion type and capable of pumping 20,000,000 gallons of water per 24 hours, with a total lift of 150 ft. Three of the pumping engines will be installed at the new pumping station to be built at the corner of Central Park Ave. and Fillmore St., and the other three at the new station to be built at Springfield Ave. and Bloomingdale Road. Mr. Joseph Downey is the Commissioner of Public Works.

◆

AN ENGLISH TANK LOCOMOTIVE built for the Wirral Railway has twelve wheels, of which only four are driving wheels, there being a leading and a trailing four-wheel truck. The engine has side tanks and a rear coal bunker, and its general dimensions are as follows:

Driving wheels (4)	5 ft. 2 ins.
Truck wheels (8)	3 " 0 "
Wheelbase, driving	7 " 6 "
Wheelbase, total	30 " 2 "
Length over all	38 " 9¼ "
Weight on driving wheels (Front, 33,908 lbs.; rear, 34,188 lbs.)	68,096 lbs.
Weight on leading truck	30,576 "
" on trailing truck	35,308 "
" total, in working order	133,980 "
Cylinders	17 × 24 ins.
Valve gear	Link motion.
Boiler pressure	160 lbs. per sq. in.
Boiler plates	Steel.
Tubes	Iron.
Firebox	Copper.
Heating surface, tubes	928 sq. ft.
" " firebox	93 " "
" " total	1,021 " "
Capacity of bunker	132 cu. ft.
Capacity of tanks	2,280 U. S. gallons
Brakes	Vacuum.

◆

THE ATLANTIC & PACIFIC RAILWAY TUNNEL CO., which was organized some years ago by the late "Brick" Pomeroy, is now in difficulties and it does not seem likely that its purposes will ever be carried out. The project was to construct a tunnel five miles long through a ridge of the Rocky Mountains in Colorado, for the combined purpose of tapping alleged great deposits of gold and other ores, and of opening a short line of railway communication which would cut down the distance between Denver and Salt Lake City from 770 to 520 miles. The company was organized in 1880 and work went slowly on for some years, but at present only about 1½ miles of tunnel are completed, and this tunnel is, it is understood, only a heading and not of full-sized section for railway purposes. The project was most extensively advertised and a large aggregate amount was subscribed, mainly by small investors. No work has been done for some two or three years, and it is now claimed that owing to non-payment of taxes by the officers of the company the property is liable to be sold to recover the amount of the taxes.

◆

THE INTERLOCKING OF STREET RAILWAY CROSSINGS of steam railways at grade is to be carried out by the Brooklyn Heights Electric Ry. at its grade crossings of the Long Island R. R. The signals will stand normally at "stop" for the electric cars, and will not be lowered by the towerman until he is advised that the block is clear.

◆

THE GROWTH OF STREET RAILWAY TRAFFIC IN New York, in the last 30 years, is thus set forth in the presidential address of Mr. Rogers before the late convention of the New York Street Railway Association at Binghamton:

Date.	No. of lines.	Elevated traffic.	Total traffic.
1865	11	....	79,618,818
1875	13	644,025	140,582,793
1878	15	9,236,670	169,105,739
1883	15	92,124,943	266,164,236
1893	16	219,621,017	453,652,964

The Railway Commission's report of 1895 says that the operating expenses, interest, taxes and rentals of all street railways in the State aggregated 91½% of their gross receipts. At this rate, says President Rogers, the dividend on one 5-ct. fare amounts to 4¼ mills. In New York a passenger can ride 12½ miles for 5 cts.; in Brooklyn, 18 miles; and in Buffalo, 13¾ miles for the same fare. Reduced to mile rates, the transportation charge would be 4, 2.8 and 3.7 mills per mile, which is claimed to be the cheapest transportation rate in the world.

◆

THE CHICAGO & SOUTH SIDE ELEVATED RY., better known as the Alley Elevated, was sold at public auction at Chicago, Ill., Sept. 16, under a decree of foreclosure. The property is capitalized at $18,000,000, but was sold for $4,100,100 to Mr. Leslie Carter representing the first mortgage bondholders' committee and Mr. G. E. Adams, representing the extension bondholders' committee. The company was incorporated in 1888, but the line was only completed in 1893, in time to start with a very heavy traffic of passengers between the city and the Columbian Exposition. Since that time the traffic has been but light and the company has had continuous financial trouble.

◆

A DUST-PROOF CAR has been devised by Mr. E. H. R. Green, General Manager of the Texas Midland R. R., and a car fitted with the necessary appliances has been put in service. According to published descriptions these are water-drenched ventilators located in the walls of the car between the windows, and water-pipes produce a shower of artificial rain in each ventilator. The water is carried under pressure through the pipes to drench each of the wire-fabric air filters in the ventilators. The power is derived from the axle, and is transmitted through the medium of flexible coiled wire bands. The same water is forced through the pipes and ventilators repeatedly, being used over and over again all day. The pumping apparatus is located out of sight under the floor. When the passenger wants a breeze, he turns a knob which throws open the air-deflector on the outside. This catches the breeze produced by the forward motion of the car, and throws it through the water-drenched air-filter into the car. This breeze may be increased, diminished or shut off entirely at the pleasure of the passenger.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week was a collision between a light engine and an engine with the pay car on the Cincinnati, Hamilton & Dayton R. R., near Connersville, O., Sept. 18. The light engine was running backward and the other engine, with its car, was thrown from the track. The engineman and conductor of the pay train and both firemen were killed, and three or four persons were badly hurt.——The Brantford express train of the Toronto, Hamilton & Buffalo Ry. was derailed at a switch at Hamilton, Ont., Sept. 17, and the engine was overturned, killing the engineman and fireman.——A broken axle on a box car caused a bad freight train wreck on the Conestoga bridge, of the Pennsylvania R. R., near Lancaster, Pa., Sept. 18. About 20 cars were derailed and smashed, but the bridge was not damaged.

◆

A PREMATURE EXPLOSION OF DYNAMITE occurred Sept. 19, on the tunnel work at Shaft No. 2, of the new aqueduct for the metropolitan water supply system of Boston, Mass., the shaft being situated at Clinton, Mass. Four men were killed. The shaft is 100 ft. deep and the tunnel extends 150 ft. in both directions from the bottom, the explosion occurring in the west tunnel. According to press reports and interviews with the survivors, the day shift at 5 p. m. had drilled 22 holes, 6 ft. deep, and in each hole was placed 6 lbs. of dynamite. The foreman adjusted the wires and the gang went to the surface. Two sections of the blast, about 14 holes, were successfully fired. The men went into the shaft to adjust the wires for the third or clearing blast (to clear the face of the work), and had hardly reached the bottom before the explosion occurred.

◆

A POWDER EXPLOSION, caused by lightning, occurred Sept. 19, at the works of the Hazardville Powder Co., Hazardville, Conn., but nobody was hurt, the explosion occurring just before the time for the men to go to work.

◆

A SUBMARINE WRECKING VESSEL is being built at the Malster shipyard in Baltimore. The inventor is Simon Lake, of Baltimore, and the boat is intended to be used in recovering goods from wrecked steamers, at any depth not exceeding 150 ft. below the water surface. The trial vessel now being built will be cigar shaped, built of steel and will be 40 ft. long and 10 to 15 ft. in diameter. Steam will be used for propulsion on the surface and storage batteries for underwater work. The estimated submerged speed is 8 miles per hour, and the boat will be fitted with bottom man-holes, derricks, powerful electric lights, etc. The wreckage would be loaded into sunken trailing boats, which will be made to rise to the surface by forcing out the water by compressed air. At least, this is the plan proposed by Mr. Lake.

AMERICAN LOCOMOTIVES FOR FOREIGN RAILWAYS.

The accompanying illustrations represent four locomotives recently built for foreign railways by the Baldwin Locomotive Works, of Philadelphia, Pa., and we are indebted to the builders for the photographs from which our cuts have been prepared.

Fig. 1 is a double-end engine built for the Spanish Military Engineers at Havana, Cuba, for the Jucaro & Moron military railway. It has six driving wheels and a four-wheel trailing truck under the tank and bunker. It will be noted that there is a feed pump worked from the crosshead in addition to the injector. The cab is armor-clad with ⅜-in. steel plates on the sides and front, and lined with ash. The doors and windows have shutters of ⅜-in. steel to slide over the glass panes when required, the shutters being provided with loop-holes in the center to allow of rifle fire to resist attacks.

Fig. 2 is an engine for the Cazadero & Tepetong Ry., Mexico (narrow gage), having six driving wheels and a leading and trailing pony truck, the wheels being mounted inside the frames. It has a large cab, side tanks and a rear bunker.

Fig. 3 is an engine of very similar type to No. 2, but having the wheels outside the frames. It was built for the Krotovka & Sergievsk Ry., of Russia.

Fig. 4 is a mogul four-cylinder compound engine for the Norwegian State Railways, and is peculiar for the wide spread between the main and rear driving wheels. The tender has trucks of the passenger car type. This engine was No. 15,000 built by the Baldwin Locomotive Works.

The leading dimensions of these engines are given in the table below.

THE NEW ST. LAWRENCE BRIDGE AT MONTREAL.

In 1859, or nearly 40 years ago, the Grand Trunk Ry. Co. completed the celebrated Victoria Bridge across the St. Lawrence River, opposite the western extremity of the city of Montreal. This structure is a single track tubular bridge, and for some years past its capacity has been strained to accommodate the business of its proprietors. The other railways terminating opposite Montreal have had to pay tribute for years to the Grand Trunk Ry. Co.; and it is stated that $5 per car has been a minimum rate for taking freight across the bridge. The Canadian Pacific Ry. has a bridge of its own at Lachine, which is some miles above the Victoria Bridge, and was completed in 1887. The Montreal Bridge Co. now proposes to build a third bridge, at the east end of the city, about 2½ or 3 miles below the Victoria Bridge, this new structure to be for railway, street railway and highway traffic. The general location was shown in our issue of Feb. 14, 1895, about which time the company advertised for competitive designs for its structure, and after some considerable delay the award has now been made, as noted in our issue of Aug. 27, 1896, the first prize going to Mr. E. S. Shaw, C. E., of Boston, Mass. Mr. C. N. Armstrong is the managing director, and Mr. Walter Shanley is the consulting engineer for the company, the offices being at Montreal.

Apart from the Grand Trunk Ry. and other lines controlled by it, there are now two other railways terminating opposite Montreal, as follows: The Montreal & Province line and the South Shore Ry., and under construction, the Atlantic & Lake Superior Ry. Besides these, the Central Vermont Ry. system and the United Counties Ry. reach St. Johns, about 20 miles from the St. Lawrence; the Drummond County Ry. reaches St. Hyacinthe, about 30 miles; the Delaware & Hudson, about 35 miles; and the Adirondack Caughnawaga line, about 10 miles from the St. Lawrence River, opposite Montreal. Several of these lines will, it is stated, be extended to connect with the new bridge and take advantage of the facilities to be provided by it. On the Montreal side of the river, besides the Atlantic & Lake Superior line, there are several shorter lines, including the Montreal Park & Island Ry., the Chateauguay & Northern Ry. and the Montreal Belt Line Ry.

In addition to the traffic to be obtained from these various railway lines, the bridge will obtain a large amount of traffic from local electric lines, special tracks being provided for their accommodation. In mid river is situated St. Helen's Island, with which the bridge is to be connected. This was formerly a fortified station of the British government, and is still the property of the crown, but the city has been allowed the use of the greater portion of it as a park, and it has now become what may be called the Coney Island of Montreal. Access to it is now had by means of ferry steamers, but as the street car lines do not reach the docks whence the steamers ply, the traffic is not as great as it might be with better facilities, though the daily attendance is large and on special days reaches to between 10,000 and 20,000. The construction of the bridge would allow the electric cars to take passengers from all parts of the city and land them on the island, and it is expected that the number of visitors would in this way be enormously increased.

The most urgent need of the bridge, however, is said to be for vehicular traffic, which is now completely suspended for nearly three months each year. During the summer season ferry steamers ply to several points on the opposite shore, but the advent of winter drives these steamers into shelter, and until the river becomes a solid mass from shore to shore there is no means of taking a vehicle across. This state of things lasts from four to eight weeks, according to circumstances. When the ice roads are opened all goes well until the hot sun of March makes itself felt, and the ice gradually softens and the roads become dangerous and are closed to traffic. Several weeks elapse before the break-up and disappearance of the ice and the opening of navigation, when the ferry boats make their appearance again. As the city of Montreal obtains a very large proportion of its food supplies from the opposite side of the river, this blockade at regular intervals raises the price of commodities, particularly to the poorer classes, who cannot lay by a store for the time of scarcity. The rapid current of the river, six miles an hour, at the place where the bridge is located prevents the placing of a pier in the channel, thus necessitating a span of at least 1,250 ft. in the clear; and as this span crosses the main ship channel, a headway of 150 ft. has to be provided.

The distance from the south shore to the city station of the Grand Trunk Ry., by its own line, is 6½ miles, while by the new bridge to the new central station, which is to be more conveniently situated than that of the Grand Trunk Ry., it will be only 3 miles. The new bridge being double track, and the line in the city being elevated, there will be no delays, while the Grand Trunk Ry. comes into the city on the level, crossing about 20 streets, where gates and watchmen are maintained. The bridge trains will be worked entirely by electricity, and in the city its tracks will be carried through the blocks on land purchased by the company, and it will in no way interfere with the streets. The company is not prepared to make public at present the location of its line or its terminus in the city.

The heavy expenditure necessary for the construction of the bridge has hitherto prevented its being built, but it is said that the Canadian government, the provincial government of Quebec and the city council of Montreal will assist in the construction of the bridge, which the company proposes to complete so as to open it during the great International Exposition to be held in Montreal in 1898.

◆

THE BERTRAND-THIEL OPEN-HEARTH PROCESS.*

By Joseph Hartshorne, M. Am. Inst. M. E.**

For something over two years past a new development of the open-hearth process has been in operation at the works of the Prager Eisenindustrie-Gesellschaft at Kladno, in Bohemia. It was devised and perfected by Mr. Ernst Bertrand, general superintendent, and Mr. Otto Thiel, steel works superintendent. The results which the inventors wished to obtain were to increase the product per furnace, to reduce the amount of refractories and additions used, to enable a poorer and more varied quality of stock to be employed, to improve the quality of the material produced and to render the control of the operations and product more certain. In all of these objects they have been successful, and have thereby considerably reduced the cost of manufacture and increased the value of the finished material.

The plant consists of one 12-ton and one 20-ton furnace, Through an incident of construction the smaller furnace stands some distance behind and to one side of the larger furnace, and at a height of about 10 ft. above it.

The relative position of the furnaces suggested the experiments by which the process was developed, and also enabled it to be thoroughly tested. The plant is not as convenient and suitable as one especially designed for the process would be, nevertheless the pecuniary and technical results have warranted its continuous operation.

The process consists essentially in dividing the charge between the two furnaces, tapping the metal from the upper into the lower one and removing the slag from this metal during its progress from one furnace to the other.

Both furnaces are at work on the basic system, although this is not an essential feature of the process. Pig-iron high in phosphorus and silicon is charged into the upper furnace with a small portion of the scrap, if desired, and also a certain quantity of ore and limestone. The remainder of the scrap is charged into the lower furnace, together with pig-iron and a small quantity of limestone. A little ore is also added, if necessary.

The upper furnace is first charged and the metal is melted and made hot. This takes about three hours. By the end of this time the metal is hot and fluid, the silicon is all in the slag and the carbon and phosphorus are to a considerable degree eliminated. It is then ready for tapping.

The lower furnace is charged about two hours later than the upper one. By the time the heat in the upper furnace is ready for tapping the metal in the lower one is also fluid.

The primary furnace is then tapped, the slag being carefully skimmed off the metal as it passes down the trough and prevented from entering the secondary furnace. As soon as the two metals mix together a very lively reaction ensues, which quiets down in about quarter of an hour. The phosphorus is then below 0.03% in the bath. The heat is finished by addition of ferro-manganese or spiegel, and is ready to be tapped, if no further improvement in quality be desired. Fifteen minutes longer in the furnace brings the phosphorus below 0.02%.

It is evident that the character of the charges in the two furnaces will vary materially with the local conditions affecting the supply of raw materials. Where scrap is cheap and plentiful, more will be charged into the primary furnace and the charge in the secondary one may contain no pig-iron at all. Where scrap is scarce and dear, none will be charged into the primary furnace, and only the commercially available amount will be used in the secondary furnace. In all cases the material higher in silicon, phosphorus and sulphur will be charged into the primary furnace and the available amount of purer material will be charged into the secondary furnace together with the necessary amount of other stock.

According to the practice now followed the charges are as follows:

	Upper Furnace. Tons.	Lower Furnace. Tons.
Basic Bessemer pig-iron	7.5	1
Steel scrap	5.5	8
Limestone	0.15	0.8
Magnetic iron-ore	0.20	none

The lower furnace is charged about two hours after the upper one. The metal in the upper furnace contains 0.6 to 0.9% of phosphorus when tapped into the lower one, while the metal contained in the lower furnace is already highly oxidized and very low in phosphorus. After uniting the two metals it takes 15 to 20 minutes to reduce the phosphorus to 0.020%.

At present from 5 to 6 heats, of 22 tons of metal charged, are made at Kladno in 24 hours. The lower furnace is empty more than half of the time. It is evident, therefore, that with two primary furnaces at least 10 heats could be made in the 24 hours. The present capacity is from 110 to 132 tons (charged weight) in 24 hours; and this will be doubled by the use of another 12-ton primary furnace, which is now being erected and will soon be at work.

In order to show in more concrete form the advantages derived from the new process, the following extracts, taken from the Kladno reports and cost sheets for the five months immediately before and after its adoption, are here given:

(The paper gives a set of tables with detailed figures. We summarize the principal results as follows.—Ed.)

Comparative results of the ordinary Open-Hearth and the

Bertrand-Thiel Process.

Consumption in lbs.—per 2,240 lbs. of ingots.

	Process, old, average,	Process, new, average,	Decrease,	
	lbs.	lbs.	lbs.	P. c.
Melting-coal	785.3	748.97	336.33	4.63
Heating-coal	126.2	55.64	70.56	55.80
Steam-coal	264.3	212.93	51.37	19.40
Limestone	344.1	162.85	181.25	52.68
Magnesite	53.7	25.09	28.61	53.20
Cost, basic refractories.	$0.597	$0.256	$0.341	$57.10
“ acid “ .	0.708	0.375	0.333	47.00
	Tons.	Tons.	Increase	
Output, ingots, per heat	15.39	18.64	3.25	21.10
“ “ pr 24 hrs.	37.64	64.89	27.25	72.30
Allowing 20 tons inc.*.	.....	64.89	7.25	20.20

*For the small furnace.

These figures give a clear idea as to what was accomplished during the first five months in which the process was at work.

The total cost of conversion was reduced 27.50%. The output increased 72.3%; but, of course, some of this was due directly to the use of a second furnace. A fair allowance for the product of this furnace would be 20 tons per 24 hours. If this be allowed for, the increase in product was 20.20%. The increase under present practice is much greater, being about 50%.

A plant of two 10-ton furnaces and one 20-ton furnace would have a capacity of at least 10 heats in 24 hours, as shown above. This would give from 200 to 240 tons of ingots. A very good product from these furnaces, run separately, would be 5 heats in 48 hours from each, or 2½ per day. This would give 25 tons from each of the small furnaces and 50 tons from the large one, or a total of 100 tons of ingots. It seems reasonable to suppose, therefore, that the capacity of such a plant would be more than doubled, if run under the Bertrand-Thiel process.

Besides these advantages, which are shown by actual figures, it is claimed that the amounts of deoxidizers and recarburizers used are also reduced, and that the loss is smaller. The work of the ten months contained in the table does not show any material difference between the two processes, so far as average loss is concerned; the difference in favor of the Bertrand-Thiel processs being only about 0.10%. It is reasonable to suppose, however, that with more experience this feature may be improved. The secondary furnace contains only a small amount of slag, which is comparatively free from oxide of iron at the end of the operation. There should be, therefore, less loss of metal as oxide; and a smaller amount of oxide in the bath, both of metal and slag, should require a smaller amount of deoxidizer to free the steel from red-shortness. This point, however, is somewhat difficult to determine, since so many specifications require more manganese in the steel than that which is necessary to make it roll well.

The control of the quality of the finished product is very complete. Steel is made to specifications within a range of from 0.06 to 1.25% of carbon. The phosphorus can be run down below 0.02% with ease; the sulphur is kept below 0.03%, and the manganese can be regulated very closely. As an instance, it may be stated that a large amount of steel has been made containing 0.80 to 0.90 carbon. This steel was used for bayonets for the Italian army and the results were very satisfactory.

The work of the past year has shown that from 65 to 75% of the sulphur is removed by this process.

THE TONNAGE RATING OF FREIGHT TRAINS.*

Mr. Brunn (Erie R. R.).—Our experience with the tonnage system began in the month of June this year, although the system has been under consideration a good many years, but we did not, until that time, make up our minds to follow it. The results have been highly gratifying to the local officers and I believe to the general officers of our company. We keep a very careful record of the number of cars in a train load and by so doing we are able to figure the money value received. A great saving has been made in light loads—that is, we haul on our line a great many cars of merchandise in which we do not get the full capacity of the cars; in some instances where our train load under the old system of loading was 30 cars we have been able to pull as high as 40 cars. Again in some instances where we were hauling heavy dead freight we had to reduce the number of cars in trains, but no doubt this was a great benefit in preventing the stalling of trains on grades, and securing greater regularity in train movements. We first started to load on the ton basis; but we now load trains by the thousand pounds or by the "M." This simplifies the work of getting the load. Instead of taking the number of cars and saying so many tons, one simply takes off the first two figures of the weight of the car. For instance, a car weighs 20,700 lbs. The car is counted as 21 Ms.

In loading a car at the warehouse, the bill of lading or shipping receipt always shows the weight of each shipment, and the shipping clerk makes a note of them, and if it is a mixed car, with different consignments in the same car, he deposits the bill in an envelope and puts the gross weight of the car and contents on the outside of the envelope. If the car is forwarded under that envelope, with the original bills, the yardmaster gets the weight from that envelope. If the bills are sent forward in advance of the car by passenger train, there is a car way bill made out, on which is shown the car and contents.

The first thing done is to take the total weights on the shipping orders before any manifesting is done, and supply the yardmaster with the information. It is a very simple matter for the clerk to take the contents of the car and put it on. The yardmaster gets the total weight and notes it on the card about as quickly as he gets the car itself, and we have loaded out from 75 to 90 cars of mixed merchandise a day, and have experienced no difficulty in the matter.

---

*Abstract of the discussion on the report of the Committee on Transportation, of the American Society of Railroad Superintendents, presented at the recent meeting at Niagara Falls. The report was given in the report of the proceedings in our issue of Sept. 17.

On a road on which coal or ore originated along the line, at points close to the terminus of a division, we might not get the weight until we were ready to move, but my understanding is that coal is always weighed at the tables where it is loaded, and in that case we would take the shipper's weight. We do not hesitate in taking the weights of the shippers, as we have found in most instances that their weights are nearer correct than our own. A track scale is not always to be relied upon for weighing coal as it goes over the table.

Mr. C. B. Price (Allegheny Valley R. R.).—On many roads I know the custom is to weigh at a railway track scale generally placed at a point where the product of a great many mines pass over it. The manifesting is made from this weight. The scale on which the most of our weighing has been done is pretty well up the line for the purpose of catching everything originating at that point. We never take the shippers' weights; they take ours, and are only too glad to get them. If they weigh their coal at the mines it is to test the weights received from us.

Mr. Trump (Pennsylvania R. R.).—It is the practice of my division to weigh the coke, for instance, which comes from the southwest branch, at some common point and to do the manifesting on those weights. The coal shippers all have their own scales, but they use our weights for invoice purposes altogether. In the makeup of trains we would be governed by the returns from the official railway scales.

Mr. Roberts.—I think you can arrive at the information you desire by approximating the capacity of the cars; that would not affect the tonnage of the train, as you get the weight sufficiently near to make up your train. Our cars are loaded at a point where there is an accumulated product of the mines; the actual weight is taken there and sent back to the shippers, and they accept our weights. So far as obtaining information for the maximum capacity of our engines is concerned, we take the estimated weight of the load and cars. With the exception of the coal trains we are not loading trains on the tonnage basis. As to trains of empty cars our first method was to add 25% to the weight of cars for an empty train, and it was not enough; it made a bad showing. At a certain point where the tonnage rating showed we could haul 77 empty cars we could actually haul only about 48, then we changed the method and added 60% to empty trains, and that is not enough, and we have about made up our minds that we should add 70 or 75%.

Mr. Knibloe (Buffalo Creek R. R.).—In order to have a perfect application of the tonnage methods we must have the facilities requisite for such application. It was the opinion of the committee, as expressed in its preliminary report a year ago, that the percentage of economies in either direction, in the time the train moved and in the additional number of cars hauled and the decrease in the trains run, was so great that railway companies could afford to go to considerable expense in putting in track scales and the employment of extra clerks in order to secure a substantial conformity to the tonnage standard, whatever it might be for the different classes of engines. As to empty trains it seems to me the number of empty cars should be that which one crew can cover with safety; the crew should be able to pass safely from the rear to the engine and not have the desire to load up to the full capacity of the engine, taking the actual stencil weight of the cars.

Mr. Potter.—The result of that would be to make a very bad showing on the hauling capacity of the engine in a certain direction, and the question is brought to your attention, "Why do you not load your engines to their full capacity?"

Mr. Knibloe.—I never had experience where the movement of loads in one direction was so very much in excess of the other direction as Mr. Potter suggests.

Mr. Price.—The question that arose is one we met the other day on the Allegheny Valley R. R., and therefore I can undertake to give an answer. If the preponderance of tonnage is in one direction, it follows there must be a large percentage of light power movement in the other. If you take one engine, returning in the direction of the light movement, and load it down with the full capacity of empties, the next might go through without any load—it might be what is called "a horse and buggy train." If you limit the load of empties under the conditions specified by Mr. Knibloe, with reference to the length of the train, facilities for signaling, etc., you will strike a fair average of partially light movement.

Mr. Potter.—I agree that there is a limit to what a certain train crew could handle. We do not attempt to handle more than 50 empties. That suggestion is all right providing you can control your empties, but if they are forced on you so that you must run light power after your empties during a certain period, you want that power coming back hauling as many empties as they can.

Mr. Price.—It never happens that we have to send power up after empties. The next train moving in that direction would have perhaps more than the average number of empties.

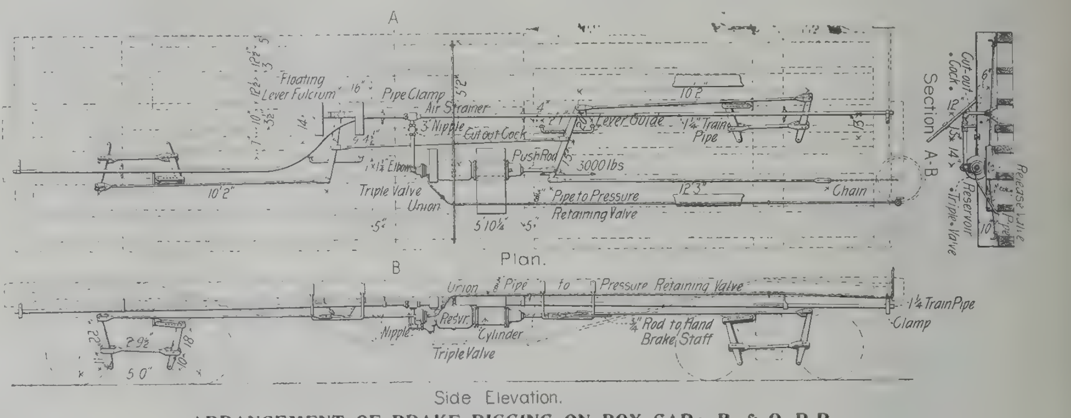
Mr. Fitch.—The question is a good deal of an experiment. After several months we came to the conclusion that the best way was to build a dynamometer car which told us exactly what the engine could do. It does not cost very much. We are building such a car. A few days' experimenting will tell you exactly what your engine can pull under any conditions.

◆

60,000-LB. BOX CARS FOR THE BALTIMORE & OHIO R. R.

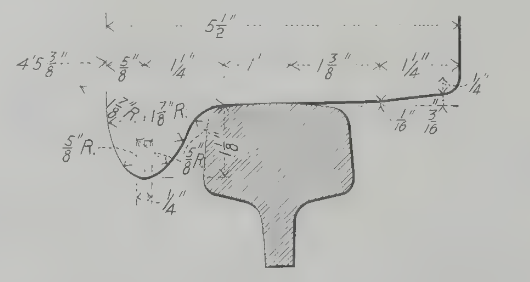
(With inset.)

A few months ago the Baltimore & Ohio R. R. placed orders for 4,600 new freight cars, and these were described somewhat fully in our issue of June 11, 1896, when an abstract of the specifications was given. Of the total number of cars, 2,300 were box cars, and the drawings of these cars are given this week on our inset sheet.



ARRANGEMENT OF BRAKE RIGGING ON BOX CAR; B. & O. R.R.

There are two side sills 5 × 8 ins., four intermediate sills 3 × 8 ins., and two center sills 3½ × 9 ins., all of yellow pine and tenoned into oak end sills 8 × 10 ins. The frame is trussed by four body truss rods 1¼ ins. diameter, with threaded ends upset to 1⅜ ins., there being a pair of rods each side 17 ins. c. to c., while the inner rods are 4 ft. 2 ins. apart. The truss depth is 22 ins. and the distance between truss-rod bearings is 6 ft. 3¼ ins. These bearings are bolted to tie-timbers 5 × 10 ins., set on edge below the sills. To the end sills are bolted oak buffer blocks 5 × 11¾ ins., 3 ft. 1 in. long, with malleable iron buffer heads. The draft timbers are 4 × 9½ ins., placed under the center sills and extending back to the body bolsters, the Buckeye M. C. B. couplers being connected up by the American continuous draw-bar. The body bolsters are built up of three white oak sticks, 4½ × 6½ ins., and two wrought-iron plates, ¾ × 6 ins., and each bolster is trussed by two 1-in. rods, with 1⅛-in. upset ends, passing through the bolster and the intermediate sills.



Wheel Tread and Rail Head; B. & O. R.R.

The side framing consists of posts and body braces 3 × 5 ins., with ¾-in. vertical rods; the end posts are 4 × 5 ins., and corner posts 5 × 5 ins. The outside sheathing is of ⅞-in. tongued and grooved planks 3 to 4 ins. wide, placed vertically, and inside these is a lining of ⅞-in. tongued and grooved plank laid horizontally; this lining extending from 2½ ins. above the floor up to the side girth, and is 5 × 4 ins. The end plate is a 4-in. plank, 14 ins. deep at the middle. The loading limit is marked by black lines, 4 ft. 6½ ins. from the floor for corn and 4 ft 3 ins. for wheat. The roof is of the Chicago pattern, composed of metal and wood, the metal sheets being covered by the outer planking. The floor is of 1¾-in. planks, 5 to 8 ins. wide, laid transversely across the sills and secured by 20-penny nails. The outside of the car is painted with three coats of brown mineral paint, with the lettering in white, and all iron-work is given one coat of asphaltum or smokestack black.

The trucks are of the diamond frame pattern, with top arch bars 1¼ × 4 ins., lower arch bars 1 × 4 ins., and tie-bars ⅝ × 4 ins. The bolster is built up of two white oak sticks 3½ × 11½ ins. and one stick 6 × 11½ ins., flitched by two wrought-iron plates ⅞ × 8 ins, 7 ft. 5 ins. long. This is trussed by two 1⅛-in. rods with 1¼-in. upset ends. Under each end of the bolster is a nest of four spiral springs, resting on the spring plank, this latter being an inverted 12-in. channel iron. Some of the cars have the American cast-steel bolster and others have the Schoen pressed steel bolster. The journals have lead lined brasses and are protected

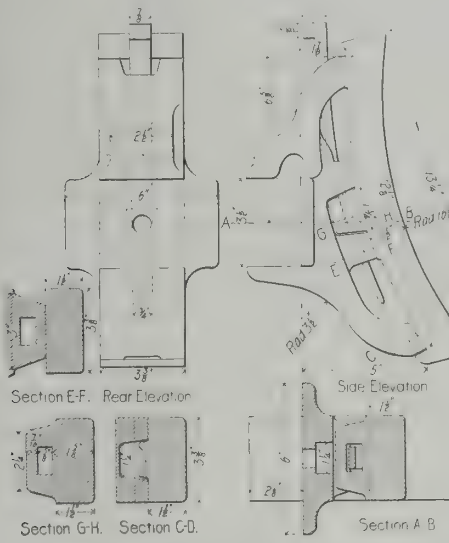
by Stier's dust guards of yellow poplar or basswood. The cast-iron wheels are pressed on the axles with a pressure of about 60,000 lbs.

The cars are fitted with the Westinghouse brake, and the general layout of the brake apparatus is shown on one of the drawings. The instructions for setting up the air brake apparatus provide that the relative angle of levers must be maintained when attaching the brake rigging to the cars. The pipes are to be blown out with steam after bending, and all connections must be perfectly tight when tested under pressure with soapsuds. Red lead must be used sparingly at joints, and put on the outside of the pipe that screws into the fitting, never on the inside of the fitting, as it is liable to get into the triple-valve and interfere with the working of the brake.



Brake Shoe for Freight Car; B. & O. R.R.

The cars were designed by Mr. Harvey Middleton, General Superintendent of Motive Power, and Mr. E. W. Grieves, Superintendent of the Car Department.

The general dimensions of the cars are as follows:

Length:	
Over end sills	36 ft. 10 ins.
Over body sheathing	36 " 11¾ "
" running board	38 " 5 "
" couplers	40 " . 1¼ "
Inside	36 " .. "
Width:	
Over side sills	8 " 10 "
Over body sheathing	8 " 11¾ "
" eaves	9 " 7 "
Inside (between girths)	8 " 2 "
Extreme (over bottom slides of doors)	9 " 8¼ "
Height:	
Rail to c. line of coupler	2 " 10½ "
Rail to eaves	12 " 6⅛ "
" to running board	13 " 4⅝ "
" to top of brake shaft	14 " 0½ "
Side sill to side plate	7 " 5½ "
Floor to carline	7 " 7¼ "
Doorway	7 ft. 3½ ins. × 5 ft. 6 "
Axles:	
Length, c. to c. of journals	6 ft. 3 "
Diameter at middle	4⅝ "
" at wheel seat	5⅜ "
Journals	4¼ × 8 "
Wheels, diameter	2 ft. 9 "
Wheelbase, truck	5 " .. "
" total	31 " 10 "
Distance c. to c. of trucks	26 " 10 "
Carrying capacity	60,000 lbs.
Cubic capacity	2,254.5 cu. ft.
Weight, empty	32,362 lbs.
Cost (approximate)	$510

BLOCK SIGNALING AND INTERLOCKING.*

Mr. Derr (Erie R. R.).—My division is divided into 43 block sections, ranging from a few hundred feet to 3½ miles. In the yards we operate the block system, the same as on the line. Our block system is largely manual, with electric bells connected between the towers; the signaling being done by the ordinary code, so many taps of the bell meaning certain moves and directions. At the outlying stations where there is a cross-over, we have the distant signal located not less than ¼ mile from the home, and running up as far as 3,200 ft. The home signal is located near the cross-over and protecting the cross-over switches, and the advance signal is about a train length ahead of the home signal. At some cross-overs we also have signals for directing the movements from the cross-over to the advance signal. A great many cross-overs are locked with the home signal, so that no movement can be made over a high speed line except when the switch is set for the line movement. Our rule or direction on signaling to our men is that they may run up to the home signal but not beyond it when at danger; that may be laid down as the fundamental principle of signaling. The home signal governs to the advance signal and no further; after bringing the train to a full stop no clear movement can be made; you give permission to go to the advance signal and no further. In other words, the advance signal cuts the block or section into two parts, and the home signal governs only to the advance signal.

Mr. Trump (Pennsylvania R. R.).—We use the telegraph block system on the main line divisions. The signals are given by the semaphore. We do not use the track circuit except in special cases. We use the automatic electro-pneumatic semaphore system, with the exception of a few electrical signals. In regard to the use of the absolute block, we have been able to do away with this feature, especially on divisions like the Western Division, where we handle heavy trains and grades. We have not money enough to put in the block stations every half mile.

Mr. Brunn (Erie R. R.): On our Buffalo Division when we first started the block signal system we found the expense of adopting an absolute block would be very great, and after considerable arguing with our people, I succeeded in getting them to permit me to put in the block, and made the block positive in reference to passenger trains—that is, a passenger train following a passenger train would block before and behind; a freight train following a passenger train was blocked before and positive block behind, etc., insuring positive safety to the passenger trains. Where a freight followed we allowed the trains to go on the block with caution signal, separating them 15 minutes apart. The blocks in many cases are seven or eight miles long. We operated that system several years with very satisfactory results. Where it was possible we let one train follow another under green signal. We finally decided to introduce the absolute block in reference to freight trains. We often found it was necessary to close up freight trains at important points, where we had ample siding facilities, and let the passenger trains (or trains of superior class) go by. In doing that we never let the following train into the block until we knew absolutely where the leading train was, then we gave the conductor or engineman an order or message indicating just where the obstruction is, and let them proceed under the caution signal. That is, perhaps, as near the absolute block as you can get; tell the man where the train is and let them go to that point by using their own judgment. Our system permits the use of the green signal under the circumstances I have stated. When we know a train is at a siding and about to pull in, then we send the order to the following train, which is delivered to both conductor and engineman, telling them the train is drawing into such siding, and allow them to go into the block under the green signal. We never give them the white or clear signal. The train order is a message which the telegraph operator is required to give to both conductor and engineman, and they cannot proceed without that message.

Mr. Trump.—I would like to see the absolute block on all railways, but with heavy trains and heavier freight trains it seems to us impossible to adopt the absolute block system. It costs us about 25% more to run under this system. Some roads use the siding, and forward trains under caution card; and also use the clearance card in case anything goes wrong. There are cases where they give the engineman a card to stop a train and deliver the card to the next operator. On the division having the Westinghouse automatic signals, with track circuits, we have to provide for the contingency of the signal constantly sticking at "stop." If a train finds the signal at danger, it comes to a full stop, and then proceeds the same as with a caution card, looking out for broken rails, etc. The time of stop required is two minutes, as it takes about that long for a freight train to get stopped and start again. Occasionally a signal may be out of order, and this sometimes occurs by the carelessness of the track-men in handling ties, dumping cinders or something of that kind. They connect the two sides of the track circuit.

Mr. Price (Allegheny Valley R. R.).—We have had, during the last six months, two short sections in the Pittsburg yard equipped with the overlapping block signal apparatus with disk signals, as described by Mr. Schreuder yesterday (Eng. News, Sept, 17, 1896). The sections are short, about ¼ mile each, protecting the operations of the yard, which is considered especially hazardous. They have worked very well, but it happens sometimes that the signal sticks at the red or "stop." It may be on account of wet weather. Wet affects the conductivity of the track sections and makes the signals slow to release from the stop position after the trains have cleared. To cover this contingency we have adopted the regulation that after a certain interval of time a train stopping at the "stop" signal may proceed. With that little regulation supplementary to the mechanical arrangements we have been able to get along very well with the signals. I wish the whole of our railway yards were protected in the same way. I recall instances where passenger trains were held for short intervals, since we had this system in operation. It is connected to the inside of the switches on cross-overs as well as the main track switches. We have had one or two cases where the yard crews, standing on the siding waiting for passenger trains to pass, would open the inside of switch so as to be ready to go ahead; the effect was to keep the signal at "stop," and produced a little delay to the passenger trains. It was due to the ignorance on the part of the trainmen, and it was only necessary to call their attention to it in order to secure its correct working. I mentioned wet weather as one of the conditions affecting the track circuits. On the Pan Handle road, where they have the track circuits, they have had the same experience.

Mr. Schreuder (Union Switch & Signal Co.).—In regard to track circuits in wet weather, we find that where tracks are laid with cinder ballast close to the rail, we have a lag in the track circuit during wet weather. Of course in working the track circuit, you must limit the length of the circuit in accordance with the condition of the track. Where the circuit passes through many switches and yards, the length should be regulated accordingly, and the battery must be located so as to be at the lowest tension possible. We can under ordinary conditions work a track circuit one mile long with one cell of battery, when the rail is not touching the ballast; when close to the ballast, as in yards generally, we are obliged to have more battery. In some cases we have had considerable trouble with the track circuit where it is parallel with trolley roads, but have overcome it by using a double insulation and grounding, in some cases.

THE POLE GAS-MOTOR STREET CAR.

By T. C. J. Baily, Jr.

A street motor car operated by a gasoline engine has been tried recently on the line of the Anacostia Ry. Co., of Anacostia, D. C., and its mechanism is the invention of Mr. T. C. Pole, of Washington, D. C.

This motor may be described as a 20-HP. horizontal gas engine, with cylinder 9×14 ins., mounted in the center of an open car, 20 ft. long and with a seating capacity for 19 passengers. The motorman on the front platform handles a wheel which, being turned to the right engages the sprocket wheel and chain by means of a friction clutch to two 36-in. driving wheels; while turned to the left, it throws off the clutch and puts on the brakes. The cylinder is just above the floor, with a 100-gallon water cylinder, or tank, above it. To one side and on the level with the water cylinder is the gasoline tank, made of ¾-in. boiler iron, 14 ins. outside diameter and with a capacity of 7 gallons. Two heavy fly wheels, 5 ft. 6 ins. diameter, steady the engine, the engine and fly wheels running constantly at a uniform speed independent of the speed of the car. There are two sets of gearing, for speeds of 6 and 12 miles an hour. The explosion is at present accomplished by a spark from four Leclanche cells, and the engine exhausts into a muffler underneath the car, this exhaust being scarcely audible. The entire outfit, including engine and car, weighs about seven tons and is designed to haul one or two trailers. The following results were obtained on a trial trip made about midnight of August 20.

The motor was geared up to a maximum speed of six miles per hour, the test not being for speed so much as for economy and efficiency. It took about a minute to start the engine, after which it ran steadily, the car itself being started and stopped several times to see how quickly it responded. One hill, 1,300 ft. long, beginning from a curve, was climbed, its grade varying from 2.6 to 5.2%, with 4.14% for 600 ft. The car took the hill easily. On a 4.14% grade it was stopped and started with no perceptible slipping. A start was also made from the middle of the sharpest curve on the road. The hill mentioned was the only one encountered on the run of 9,400 ft. The road is a rough one, about half a mile of it not having been used for several years and being covered with sand. Over this part the speed was about 4 miles, but for some distance 6 miles per hour was actually maintained.

As a consequence of the rough track, only when the engine was running and the car at rest could any opinion of the vibrations and noise be formed. This vibration was considerable and mostly longitudinal; heavier fly wheels might lessen it. The wooden casing was taken off, so the noise was far more than it would be in actual service and was very great. It should be remembered, however, that the parts are new and necessarily work stiffly. The gasoline also smoked badly once after a long stop, due to an overcharge, but while running there was only a slight odor.

The inside diameter of the gasoline tank is 12½ ins. At the end of the run the depth of the gasoline was measured and it was found that 1½ ins. had been used. This means 0.8 gallon for a distance of 1.8 miles. Taking the retail price of gasoline at 8 cts. per gallon (what it cost the parties making the test), would give on this run a cost of 3.6 cts. per mile for fuel. The temperature of the water rose from 80° at the start to 120° at the finish.

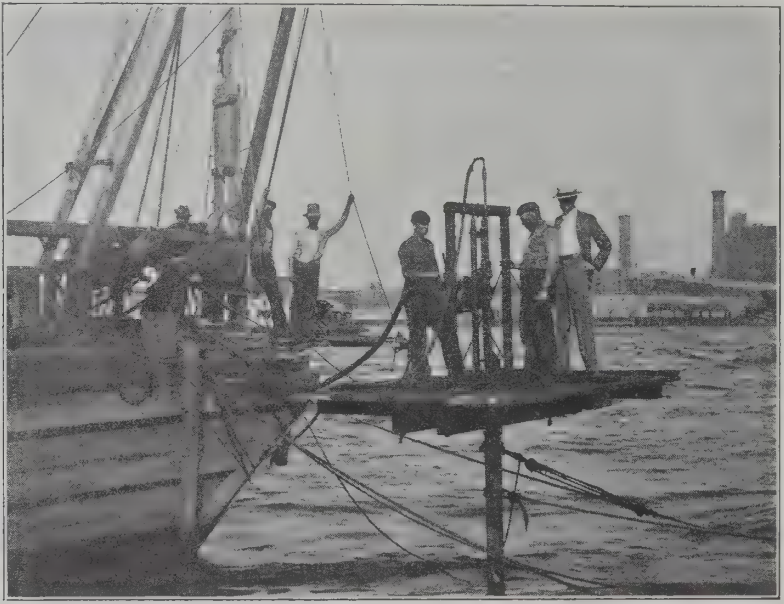
---

*Abstract of discussion at the meeting of the American Society of Railroad Superintendents, at Niagara Falls, N. Y., Sept. 9, 10, 1896.

Mr. Pole has received permission to run his car over the Belt Line tracks and also those of the Brightwood electric line, which has a smooth track and a couple of long grades.

DIAMOND DRILL BORINGS FOR THE NEW EAST RIVER BRIDGE PIER FOUNDATIONS.

As a preliminary to founding the towers of the new East River bridge, an exploration of the character of the soil and the depth to the solid rock at each tower site was essential. This was at first attempted by driving pipe to the rock, or to what appeared to be rock, and then exploding a dynamite cartridge on the surface of the supposed rock. If the pipe failed to sink any further the testing party assumed that bed-rock was reached; and on this supposition rock was indicated at 50 ft. below the water surface on the New York side, and at 75 to 80 ft. on the Brooklyn side.



MAKING DIAMOND DRILL BORINGS FOR THE FOUNDATIONS OF THE NEW EAST RIVER BRIDGE PIERS.
The New York & New Jersey Well Co. and the American Diamond Rock Drill Co., Contractors.

These tests, however, were not satisfactory and conclusive to the engineer of the bridge, and he decided to have borings made with a diamond drill to such depth as would establish beyond doubt the true position and character of the rock foundations. Bids were called for and the contract was let to the New York & New Jersey Well Co. and the American Diamond Rock Drill Co., of New York.

The method of carrying on the diamond drill work is indicated in the accompanying photograph. The strong tideway and the heavy swell from passing steamers made work from a floating platform impossible, and to drive piles for each boring would have added heavily to the expense when the depth of water was considered; this depth was comparatively small on the New York side, but on the Brooklyn side the water ranged from 49 to 60 ft. deep. The use of a trussed and anchored pipe, similar to that employed on the test-borings in the Northumberland Straits, was also rejected, owing to the variation in depth and the desirability of starting some of the holes with small pipe and others with pipe of large diameter.

The plan of the work finally adopted was as follows: A pipe was first jetted and driven to the bed-rock by the use of the boring machines of the New York & New Jersey Well Co. These machines were mounted on the bow and stern of a large scow; and heavy drive-pipe was used, with the holes usually started with a 6-in. pipe, though 8-in. pipe was driven down in some places. On reaching a boulder that could not be broken up, or driven aside, a hole was drilled through it with the drop-tools, and a smaller pipe was inserted and driven down; and this process was repeated until bed-rock was assured. In several instances a boulder was mistaken for solid rock, until the diamond drill exposed its pretensions. Bed-rock once actually reached a 2-in. pipe was seated in the rock in such a manner as to form a sand-tight joint; the scow was drawn back a few feet from the hole and a platform, 8 by 10 ft., made of 6 by 6-in. timbers and floored with 2 by 6-in. plank, was lowered over the top of the 6-in. pipe and firmly clamped to it by bolts. The pipe, with its platform, was stayed against vibration by means of separate anchors and by purchases attached to the anchor lines of the scow. The diamond drill and its frame was then mounted upon the platform; and for these borings a very light drill, designed for underground mining exploration, was adopted and proved well suited to the work. Steam hose and water hose connected the drill on the platform with the boiler and pump on the scow.

The original pipe-borings were found to be misleading, after the diamond drill had been set to work. Instead of 50 ft. to bed-rock, on the New York side, the true depth was found to vary from 46.1 ft. to 68.3 ft.; and on the Brooklyn side, the true depth ranged from 80 ft. to 104 ft. In only one case out of 22 holes bored did the two sets of borings agree; in all other cases the supposed solid rock proved to be merely a boulder. The actual distances bored into the bed-rock by the diamond drill ranged from 10 ft. to 20 ft., these depths being considered sufficient to prove the character of the foundation. In nearly every case a few hours' work, after setting up the drill on the platform, was all that was required to complete the hole, and no difficulty was experienced in working from the platform, notwithstanding an unusually strong tide and heavy swells from passing boats. A core was furnished for each hole, showing conclusively the character of the rock. As the small drill used had a capacity of 350 ft. the holes could easily have been carried deeper, had this been deemed desirable. In all, 22 holes were drilled; 10 on the New York side, at the foot of Delancey St., and 12 on the Brooklyn side, at the foot of South Fifth St.

The use of the fixed platform proved entirely successful, and is believed to have been more economical than any other method that could have been proposed; and the results indicate that this method should have an extended application to problems of submarine boring. During the progress of the borings at this place, a new process for shutting off seams in bore-holes was successfully tried and much facilitated the work. This process was invented by Mr. Garvey, in charge of the diamond drill work of the American Diamond Rock Drill Co.; but details of the process have not yet been made public.

HIGHWAY BRIDGES.*

By Carl Gayler.**

In preparing a paper on this subject I have endeavored to bring out a few points which might explain the very limited success of former agitations for an improvement in the building of highway bridges, and to discuss at some length the present practice, not of the highway bridge companies, but of the structural engineers who have made highway bridges a specialty.

It is now four or five years since the movement for a reform in the highway bridge business was at its height. The technical papers of that time are full of editorials and letters on this question; several prominent engineers and professors of civil engineering devoted their time and influence to it; the engineers' clubs of Chicago, St. Louis and Kansas City had committees appointed and reports adopted, and in several states drafts of proposed acts of legislature were prepared and came very near being introduced. And with this the movement came to an end, after having accomplished very little; and highway bridges are being built about in the same manner as before.

As there is no doubt that an improvement in the building of highway bridges is desirable, this failure is remarkable and seems to indicate that the fault lay with the proposed remedies. There is a good deal of force in the objections first raised by Mr. Horton, of the Western Society of Engineers, against the principal proposed remedy, i. e., legislative enactments. It seems unjust to transfer the control over highway bridges from the cities and counties to the state, as the former originate the work, pay for it and have to maintain it.

A perusal of what has been written and proposed at that time leaves, furthermore, the impression that the movement was not sufficiently comprehensive; it might be characterized as efforts to secure legislation providing for expert examinations of the strain sheets of proposed new highway bridges, and examinations of such old ones, the safety of which had given rise to doubts. But how about the preliminary work, deciding on the length of span, clear waterway, foundations, character of masonry, and—assuming the superstructure to be built according to the proposed state official's directions—the maintenance of the bridge? Surely, every one of these points requires the services of the bridge engineer. Counties will have to follow the example of our large cities, and employ capable engineers for their highway bridges. Wherever in cities and counties public works are in the hands of engineers, state supervision is unwarranted; where county commissioners rely on their own wisdom a limited supervision, as proposed at the time of the late reform movements, is insufficient.

Whenever one of the periodical unusually heavy rains flood a section of the country, we read about a number of bridges having been washed out; such occurrences are generally regarded by the profession with considerable equanimity, as if it were in the natural order of things that abutments and piers are underwashed, or superstructures carried away by floods which surely should never have reached them, whilst the occasional breaking down of a highway bridge is carefully noted, and still gives rise to spasmodic appeals for legislation. Why this important question of sub-foundations was never included in the efforts of the reformers, why it is likewise hardly ever mentioned in books and treatises on highway bridges, has always been a mystery to the writer. Some remarks on this subject may not be out of place.

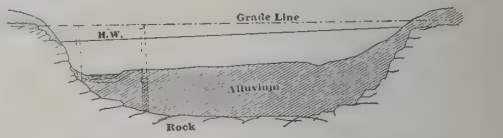


Fig. 1.—Typical Cross-section of a Stream Bed.

The cross section of a valley, as shown in Fig. 1, through which a road is supposed to be built, requiring the crossing of a creek or stream, is typical with the cases with which I had experience; it is probably also typical of the greater number of cases in this part of the country. It is a broad valley, with steep banks and an alluvial bottom. The rock is near the surface on both bluffs, the alluvium extends down to considerable depth, and the water-course is near one of the two banks. A glance will show this valley to have been in former ages the bed of a great river, which, probably assisted by the action of ice, hollowed out its immense bed in the rocks. Subsequent sinking of the land or diminishing of the volume of water, or both causes combined, raised the level of the bed of the river, and the valley filled up with boulders, gravel or sand, or with clay, from the ice period, and, closer to the present water-course, with more recent deposits. To form an intelligent judgment of the contemplated foundations, an insight into the history of the valley in by-gone ages, assisted by some general knowledge of geology, is necessary. Borings or test pits will complete what is necessary to plan the foundations and estimate their cost. The grading of the highway and the building of the substructure reduces the free waterway in time of floods, a deepening of the water channel, often, also, a shifting of the water-course, caused by the dying out of the vegetation, takes place, and these changes in the water-course are most important in designing the foundations, and,unless taken well into consideration, may cause the destruction of the bridge in short time. That this preliminary work, as well as the building of the abutments and piers, should be in the hands of the bridge engineer, will be readily conceded.

---

*From the Journal of the Association of Engineering Societies, June, 1896.

**Member of the Engineers' Club of St. Louis.

The superstructure of the American highway bridge has been developed by the highway-bridge companies, and it has been truly stated in regard to the best examples among them, that "greater strength and safety are obtained from a given amount of materials than with the methods of construction which prevail abroad." During late years, some of our leading structural engineers have given their attention to this subject, and have published books and specifications on highway bridges. A subdivision of the latter into three classes, according to their proximity to cities, assuming different live loads for each of them, is now the accepted rule. Being more familiar with Class I (or A), i. e., bridges in cities, I will confine part of the following remarks to this class:

It is generally agreed to assume for the live load, beside a concentrated load by which the dimensions of the flooring, stringers, floor-beams and hangers are obtained, a uniform load per square foot, covering the whole and portions of the bridge, ranging from 100 lbs. for short spans to 50 lbs. for longer spans. It is worth while to consider what this assumed uniform live load really means.

In the case of railway bridges the live load is simply the weight of the trains, and the unit strains in the truss members have been selected of such magnitude as to give a structure of reasonable rigidity. For the principal tensile members, 10,000 to 12,000 lbs. are customary, and for the compression members a reduction is made in the units according to the laws of the strength of columns. These unit strains are far lower than the elastic limit of the material would seem to warrant; they bear no relation to the breaking strength, and the so-called factor of safety may as well be abandoned as an antiquated expression without meaning; they have been evolved from the behavior of bridges under their daily duties. As Prof. J. P. Snow, in a recent discussion on the strength of iron railway bridges, puts it: "What is the basis of the present units? Examinations of bridges in service. In order that a bridge may be satisfactory it must remain rigid under trains and deflect but very little. These conditions can only be obtained by using low units." Now, with highway bridges, the case has just been reversed. We start out with unit strains borrowed from the railway bridge practice (increasing them, however, about 25%, for some reason not easily explained) and then choose the live load with the view of obtaining a satisfactory structure. It is well to keep this in mind; attempts to explain the customary live loads for highway bridges in any other way are misleading, if not dangerous.

Since the substitution of steel for iron, some engineers specify for highway bridges of the former material an increase in the unit strains of 20%. Granted that the ultimate strength of steel is 20% greater than that of iron, and the elastic limit even more, this increase in the units is, for the reasons stated above, not justified, as the modulus of elasticity of steel exceeds that of iron but little. By far the greater number of highway bridges, with their plank floors, are light structures; there is little mass in the metal to overcome the effects of the jolting of wagons over the rough planks, or of the trotting of horses; the vibrations are accumulative and we should be slow in adopting an increase of units. Increasing or doubling the units for the dead load should only be resorted to for very long spans, or for bridges with extremely heavy floors. I may be permitted to state here that my experience in this city with four steel spans of 120, 135, 150 and 220 ft. length, designed for the live load of Cooper's A, but for unit strains of iron railway bridges, no increase in them being made for units under dead load, has been such that I have never felt guilty of a waste of material in designing them, and that they have convinced me that the usual specifications for this class are too light.

Specifications and books on highway bridges and standard details for the same, as published in the latest works, have left the impression on the writer that this subject has not been treated with the conscientious care bestowed on other structural work. Whether the temporary and unsatisfactory character of most of the floors, or the fact that bridges built in accordance with these books and specifications are still far above the general practice all over the country, or the certainty that the bridges when completed will in nine cases out of ten be neglected and go to wreck and ruin anyway, can explain their neglect, I am unable to say.

The consideration of rigidity, which have led to the selection of these live loads, should be the guide in regard to lateral connections and the results of our experience with railway bridges should with equal care be applied to the highway bridge. In all through spans rigid connections of floor beams with posts and bottom chords should be insisted upon, not that perfectly safe hangers could not be designed—the latter having even a slight advantage in applying the load centrally to the posts—but the gain in lateral stiffness is too great to be thrown away. It is impossible to prevent altogether a distortion of the structure in a storm or under a load applied close to one of the two trusses; but with deep floor beams well riveted to the posts and top lateral struts firmly attached to top and bottom of the top chord, as sketched in Fig. 2, considerable resistance is gained; with details as shown in Fig. 3, next to none.

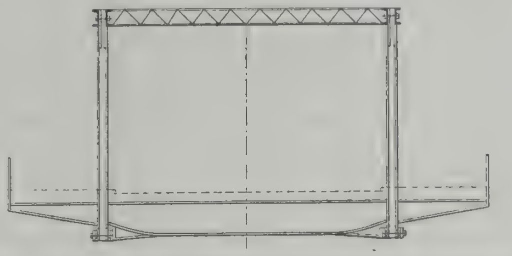

Fig. 2.—Cross-section of Bridge Truss, with Riveted Floor-Beam Connections.

There is one feature in through bridges to which full justice has never yet been done; it is the top lateral bracing. The universal custom is to design it to withstand the wind pressure (generally assumed to be 150 lbs. per linear foot of top chord). Now, there is not the least doubt that it should be made strong enough to resist the wind forces, but there is just as little doubt that if a bridge were thoroughly protected against wind, the top lateral system would still have to prevent the top chord from buckling; more than that, I am convinced that no storm ever strains it as the top chords do under their full duty. Anyone standing on a railway bridge with a train moving over it can satisfy himself on this point. It seems to be against sound judgment to design the top lateral system of a through span on the same supposition as the bottom lateral system of the deck span. This is one of the many instances where the strain sheet alone is no sufficient guide. The engineer has to use his experience and judgment to design a lateral system of sufficient rigidity; no theory in the world will enlighten him on the amount of lateral pressure exerted by an exceedingly long column. Mr. Waddell, in his book on highway bridges, states in this respect, without, however, entering into the question, that the top lateral rods in highway bridges up to 200 or 230 ft. length, if proportioned for wind pressure alone, are too light.

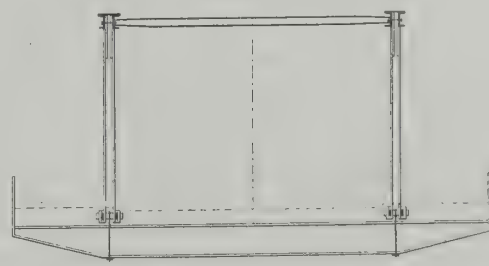

Fig. 3.—Cross-section of Bridge Truss with Floor-Beams Hung.

The above remark that the strain sheet does not cover every case applies with equal force to the specifications. It has been too much the custom to let highway bridges under a set of specifications, limiting the work of the consulting engineer—in case an engineer is consulted at all—to checking the figures and sizes. This custom, more than anything else, has made a highway bridge superstructure a mere merchandise. Nothing is, for instance, easier than to specify "a substantial railing" for a bridge, yet nothing is more indefinite and more difficult to enforce. Specifications are necessary, but we need even more the judgment of the engineer; we need more designing and less standards.

I have no intention of entering into the question of the relative superiority of pin-connected or riveted highway bridges, but there is one type in which the later are infinitely superior to the former, i. e., the short span pony truss. If designed with pin conections the lack of lateral stiffness is exceedingly difficult to overcome; with a riveted design we easily obtain a most excellent structure.

The subject of floor systems could easily be made to take up your whole time for an evening, and will not be discussed beyond calling attention to the new departure which has been occasioned through the advent of the electric motor car. That it will be of the greatest moment is apparent; we have in this city motor cars, weighing, when crowded with people, 24 tons, carried on two trucks 25 ft. apart; we have others of 18 tons weight when full of people, the trucks being spaced 14 ft. c. to c. In the first motor cars the load on each truck was distributed equally on both axles; to gain in tractive force the pin was then shifted so that about 75% of the load came on one axle, and in the latest cars (on Jefferson and Grand Aves.) the whole weight is caried on the driving axles. The first motors of 15-HP. have been succeeded by 25 and 50 HP. motors; girder rails, 6, 8 and 10 ins. deep have taken the place of the flat rail of the old street cars. It is not more than six years since electricity began to be generally applied to the city and suburban transportation, and it is not likely that the motor car, especially on long suburban lines with heavy grades, has attained its greatest weight.

Assuming now a bridge to be completed, the work of the engineer is still not over. In a few years the floor will need looking after, parts of the ironwork and railing require attention and the paint will begin to show those ugly spots which indicate that the work of deterioration has begun. This question of painting is the bane of the structural engineer's life, the one point where his knowledge is at fault and where his only recourse is to get the rust scratched off and new paint smeared over it. It does not matter very much what kind of paint he uses, iron oxide, lead paint or asphalt, so long as he tries to get a good brand and makes the most of his limited knowledge of the oil and the pigment; in all probability he will use them all in turns and in turns be disappointed. Protection of metal against atmospheric influences by paint applied cold is temporary. Rusting is most to be feared and most difficult to prevent on surfaces which are close together without being in close contact throughout, as at pin joints between the heads and eyebars and the adjacent portions of the posts and chords. Taking apart old pin-connected trusses we find the greatest corrosion on the sides of eyebar heads. It would not seem to be impossible to remedy this by filling these spaces with impervious material; to my knowledge this has been successfully done on the lower chords of the heavy Pauli trusses of the Monongahela bridge at Pittsburg. In riveted work there is no excuse for such dangerous spaces between different members, but we still find too often, through faulty riveting or where rivets have been spaced too far apart, that we can insert the blade of a knife between angles and plates, especially at the stiffeners of large web sheets.

Such weak points will probably never be quite overcome; the wonderful example of the Eads bridge, where the sides of the eyebar heads of the main arches and the adjacent sides of the joint blocks were planed and all the exposed joints of the covers of the tubes were carefully calked, will never be imitated, but the designer of structural work should keep this question always in mind.

The action of corrosion in wrought-iron work in cases where painting is utterly unavailing—and it has been my luck to have a number of such cases under my charge—is peculiar. A hard shell of corroded iron of pretty uniform thickness forms over the whole exposed surface; this shell scales off to make room for the formation of another shell, and this process goes on until nothing is left to scale off. It might not unreasonably be supposed that this process of scaling off in layers is peculiar to wrought iron as a material rolled and welded in layers, and that steel, being a homogeneous crystalline metal, would better resist the attack of rust. Should this prove to be true, what a splendid bargain did we make in exchanging iron for steel!

BIDS FOR TORPEDO BOATS were opened at Washington on Sept. 18. The proposals covered three 30-knot boats on builder's own plans and smaller boats of 20 and 22½ knots on both department and builders' plans. The prices bid were as follows:

	30-knot boats.		
	Price for each, for		
	One.	Two.	Three.
Union Iron Wks., San Francisco.	$227,500	....	....
Bath Iron Wks., Bath, Me.	....	$194,000	$189,000
“ “ another proposition.	....	235,000	....
Herreshoff Company	218,000	....	206,000
J. H. Dialogue Co., Camden, N. J.	260,000	255,000	......

	22½-knot boats.		
	Prices for each, for		
	One.	Two.	Three.
Columbian Iron Wks., Baltimore.	$79,000	$79,000	$79,000
Moran Bros., Seattle, Wash.	.....	.....	94,255
Bath Co., Bath, Me.	.....	.....	80,000
“ “ for 3 25-knot boats.	.....	.....	123,000
Herreshoff Co.	.....	.....	80,000
“ “ Cushing design.	.....	.....	92,500
“ “ Cushing modified.	.....	.....	78,500
Wolf & Zwicker, Portland, Ore.	.....	.....	75,100
G. Lawley & Son, Boston, Mass.	83,500	.....	78,800

	20-knot boats.		
	Price for each, for		
	One.	Two.	Three.
Columbian Works	$49,000	$49,000	$49,000
“ “ on their own design	45,000	45,000	45,000
Moran Bros., Seattle	59,640	.....	56,928
Herreshoff Company	40,000	.....	37,500
Wolf & Zwicker, Portland	.....	.....	45,000
Providence Steam Engine Co., R. I.	.....	51,600	48,650
Lewis Nixon, Elizabeth, N. J., on his own design	69,000	.....	68,000
C. Hillman Ship & Eng. Co., Phila	.....	48,000	.....
J. H. Dialogue Co.	.....	58,500	.....
G. Lawley & Sons, own design.	61,500	.....	54,835

The proposals were much complicated, by combinations of classes and by alternate designs of several types. These will have to be carefully examined before any award can be made. The bids were in the main reasonable and the number of bids gives general satisfaction.

Immediately upon the heels of an announcement that the New East River Bridge Commissioners would receive proposals for constructing the foundations of the New York tower, on Oct. 7, comes a statement that work will probably be delayed owing to a lack of funds. The work contemplated is to cost approximately $500,000, and this official, "high in authority in the Commission," says that this money is not on hand, and they do not know when it will be available. The late advertisement for bids for bonds brings out the unpleasant fact that $50,000 of the bridge bonds recently offered by Controller Fitch are yet unsold, and the $100,000 previously disposed of were taken by the Uhlmann syndicate and paid for with a portion of the money received by that syndicate in return for the right of way. Both New York and Brooklyn are having difficulty now in advantageously disposing of their bonds, and until the financial horizon clears up somewhat the sale of $15,000,000 bridge bonds, upon which construction depends, is problemetical, to say the least.

◆

In the purchase and laying out of plant on large construction works, it is comparatively rare to find much consideration given to the questions of efficiency and economy in operation, the general impression being that the temporary character of the work, the shifting of the plant during the work, and the rough handling to which the plant is subjected, make it not worth while to go to much expense to secure economical operation. This is no doubt true to some extent, especially on smaller jobs, though even in such cases gross and unnecessary waste and inefficiency (with consequent increased expense and reduction in profit) are too often evident, owing in general to the failure of the contractor or his subordinates to see the relation between an inefficient or badly handled tool or machine and the net financial results of the work. On large works, however, where large sums of money are involved, where a considerable amount of plant is required, and which will continue for many months or even years, it is manifestly to the contractor's interest to carefully consider the most efficient and economical plan of operating his plant, taking into consideration the conditions under which it will be worked. In another column of this issue we describe at some length the compressed air power plant and power transmission system installed for operating the tools and machines on the Jerome Park reservoir contract, a piece of work which involves an expenditure of about $5,500,000, and will extend over nearly seven years. Instead of having a number of small steam boilers scattered over the work, which is the common arrangement on construction contracts, there is one central power plant, which requires the attention of but two men and may be operated almost as economically as the permanent power plant of a factory. The result will almost necessarily be a great saving in fuel as compared with a plant using separate boilers, as the numerous small boilers generally employed are not adapted for nor handled with any view to economical fuel consumption, the main thing in the attendant's mind being usually to keep the steam up to the blowing-off point. The pipe line transmission system is very flexible and can be shifted and extended to reach any part of the work with little trouble or expense. We believe this is the first case in which compressed air power transmission has been employed on any such extensive scale for contract work, and it certainly seems to be well adapted for the conditions under which it has been established.

◆

An interesting question connected with the launching of corporations and the early marketing of their stocks and bonds came up in the late hearing of the Maritime Canal Co. before the Massachusetts Railway and the Harbor and Land Commissions. This company was incorporated by the last Legislature to build a ship canal across the Cape Cod peninsula, and the act stated that the issues of stock and bonds should be subject to the law of 1894 relating to similar issues by street and steam railways. The company petitioned that the joint boards approve of the total issue authorized, or $6,000,000 in stocks and $6,000,000 in bonds. But the law of 1894, in dealing with street and steam railways, distinctly says that the Commissioners shall approve "from time to time" such amounts as shall be deemed by them to be reasonably requisite for the purposes intended. The Commission holds that it cannot, under this law, approve of the whole issue at once; and the company says that without the whole of the issue to put up as collateral they cannot raise the money necessary for the work; and here the matter rests. Ex-Governor George S. Boutwell, in arguing the case of the Maritime Company, contended that this was an enterprise entirely differing from a railway; that the projectors could not go into the market for subscriptions, but that bonds must be sold in such a way that the issues will go hand-in-hand with the enterprise. Contracts must be made with contractors for the whole issue, or the canal would never be built. He also explained that the contracts were to be paid for in stocks, and the stock and bonds would be issued to pay for work done on the engineers' certificates. Chairman Sanford of the Railway Commission, held that the law applied in this case and the Commissioners could not say at this time that $12,000,000 was a reasonable amount for the total issue. Mr. Sanford held that if the stocks and bonds were thus approved by the Commissioners, they would go to the contractor who would sell them to the public with the board's approval upon them, and market them mainly upon this approval. Nor would he consent to approve of the issue of $250,000 of stock and $250,000 in bonds, which the petitioners finally asked for to pay for preliminary surveys, for the reason "that there was not one cent's worth of property to secure these bonds;" and he suggested that if the promotors had the faith in their enterprise which they professed, they should raise this necessary $500,000 among themselves. But even if they did this he would not advocate the approval of the entire issue, but would do as the law prescribed.

◆

To the average promotor this is a new and most objectionable manner of handling an issue of stocks and bonds. Under former and well-established usage it was the general public, and not the promotor, who took all the financial risk of any similar enterprise; and it was the business of the "construction company" to place the issues where money could be obtained for them—and to reap the profit, if any profit there was. Massachusetts is far in advance of other states in her laws regulating the marketing of bonds by railway and other public corporations and in her attempts to regulate a privilege too often abused. The law of 1894 may be annoying to those managing certain enterprises of this character in compelling them to resort to new methods of raising the preliminary funds required; but its tendency will also be to eliminate projects depending more or less upon chance for success, and also to lessen the amount of money sunk by the public, here and abroad, in investments of doubtful merit. It is true, that no one can foresee the outcome of every enterprise of large dimensions, nor can any one tell whether it will ultimately be a profitable or a losing affair. But it is time that the investors of this country took fewer chances than in the years past; and any laws should be welcome that tend to lessen these chances by placing more responsibility upon the promotors of an enterprise and by establishing honest and intelligent supervision over the preliminary stages of undertakings that are ultimately to cost millions.

◆

The new open-hearth process of steel making, described on another page of this issue, is really only a moderate variation from present current practice; but the results obtained, amounting to a reduction in the cost of conversion of over one-fourth, make the process deserving of study. The many improvements in open-hearth work which have been introduced during the past few years, among which we may note especially the American tipping furnace, are tending all the time to reduce the cost of open-hearth work and to make it more similar in economy and enormous output to work with the Bessemer converter.

EFFECT OF THE RATE OF COMBUSTION UPON THE EFFICIENCY OF STEAM BOILERS.

The paper of Prof. W. F. M. Goss, published elsewhere in this issue is an important contribution to our knowledge of the effect of high rates of combustion upon the efficiency of locomotive boilers. It has long been known that if there is no change in the ratio of heating to grate surface in a steam boiler an increase of the rate of combustion beyond a certain limit (which limit is somewhere in the neighborhood of that required to produce an evaporation of about 4 lbs. of water per sq. ft. of heating surface per hour), will make a decrease in economy. One of the causes of this decrease is clearly revealed in the increase of temperature of the chimney gases which is commonly found when the boiler is driven beyond the rate named—and is the insufficiency of the heating surface to abstract the heat generated in the furnace. In such a case the decrease of economy is not due strictly to increasing the rate of combustion on the grate, but to the generation in the furnace of a total quantity of heat so great that the heating surface of the boiler is not capable of absorbing as great a percentage of it as it does when the amount of heat generated is less. The question has often been raised whether a high rate of combustion of itself is not favorable to high economy. For example, suppose a certain stationary boiler to have a ratio of 30 sq. ft. of heating surface to 1 sq. ft. of grate surface, that 15 lbs. of coal are burned per hour per sq. ft. of grate, and that 4 lbs. of water are evaporated per sq. ft. of heating surface, equivalent to an evaporation of 8 lbs. of water per lb. of coal, might not the economy be improved by cutting down the grate surface one-half, making a ratio of 60 to 1, and by increasing the force of the draft so as to burn the original quantity of coal on the reduced grate, that is to burn it at double the original rate, or 30 lbs. per sq. ft. of grate? The answers to this question in hitherto have shown quite a difference of opinion, but the tendency in recent years, especially among those experienced in the use of bituminous coal, seems to be toward a belief in the greater efficiency of high rates of combustion on a relatively small sized grate, that is with a high ratio of heating to grate surface. The experiments of Prof. Goss give no definite answer to this question as far as stationary boilers, with rates of combustion ranging from 10 lbs. to 40 lbs. per sq. ft. of grate are concerned, but they do show some of the reasons why in locomotive practice very high rates of combustion tend to decrease of efficiency. His experiments were with four different rates of combustion; viz.: approximately 60, 80, 120 and 240 lbs. per sq. ft. of grate per hour, the grate surface being cut down in the tests after the first respectively to ¾, ½ and ¼ the full size, so as to make the total amount of coal burned per hour approximately the same in each of the four tests. The results of the tests, expressed in terms of efficiency of the boiler, 100% representing perfect efficiency, or the absorption by the boiler of the total heating value of the coal, were respectively 61, 59, 56 and 50%.

Prof. Goss makes an attempt to determine to what the increased losses in the three last tests, as compared with the first, were due. The total amount of coal burned, and presumptively the heat generated in the furnace, in each case being the same in each of the four tests, the question of possible deficiency in extent of heating surface is eliminated. The possible conditions which may cause the decreased economy with increased rate of combustion are thus apparently narrowed to these three; viz., 1, imperfect combustion of the coal; 2, excessive air supply beyond that required for proper burning of the coal; 3, loss of coal in the sparks blown out of the smokestack. The investigation as to the effect of the first two of these conditions was made by analyzing the gases, and as to the third by weighing the sparks collected in the smoke box and those discharged from certain selected portions of the total area of the top of the stack which are considered to be representative of the whole area, calculating therefrom the total spark loss, and analyzing the sparks to determine their heat value.

The result of these investigations Prof. Goss has graphically shown in Fig. 2 of his paper. The greatest source of loss by high rates of combustion in ordinary practice, when the grate surface is not cut down, is due to insufficient extent of heating surface. When this source is eliminated by cutting down the grate surface in proportion to the increased rate of combustion the next important source of loss is in the sparks blown into the smoke box and out of the stack. With about 6,500 lbs. of coal burned in each of the four tests, the total amount of sparks lost was respectively 369, 571, 772 and 1,058 lbs., the loss increasing as the rate of combustion increased.

Prof. Goss's diagram, and also the text of the paper, show that he considers that the losses due to imperfect combustion and to excessive admission of air increased with the increased rate of combustion. With this statement we regret to be compelled to take exception, and to say that it is not proved by his data. On the contrary, his results appear to us to indicate that with the reduced grate surface the only loss which increases with the rate of combustion is the spark loss, which is serious enough, and that the loss of efficiency due to excessive admission of air or to imperfect combustion was practically constant in all four of the tests. In support of this opinion we have the following data:

Test No.	1.	2.	3.	4.
Lbs. of dry coal fired	6,443.0	6,522.0	6,514.0	6,227.0
Lbs. coal equivalent in heating value, total w't. sparks	277.0	457.0	664.0	963.0
Total heating value coal lost in sparks, %	4.3	7.0	10.2	15.5
Total heating value coal absorbed by water in boiler, %	61.4	58.5	55.9	49.6
Sum of the last two items	65.7	65.5	66.1	65.1
Loss, efficiency, all causes,* %	34.3	34.5	33.9	34.9

*Other than sparks.

The last line of figures shows the total loss due to heat carried away in the chimney gases, to imperfect combustion and to radiation. There is no evidence here that any one of these losses tends to increase with an increase of rate of combustion, for the differences between any two of the four figures given above are well within the limits of error of the observations. If our view of the matter is correct, then the diagram, Fig. 2, given by Prof. Goss, should be modified by causing the triangular area a d e, which he says represent the extra loss by driving the rate of combustion above 50 lbs. per sq. ft. of grate per hour, to disappear, and the line a d to become horizontal.

Prof. Goss calls attention to the great excess of air passing through the fire in the third and fourth tests, and says " it would appear that this cause must have operated to reduce the performance of the boiler as the rate of combustion is increased." He also says that the presence of carbon monoxide (C O), which occurs in the fourth test only, is accepted as proof of imperfect combustion. Undoubtedly either a great excess of air supply or the presence of carbon monoxide in the chimney gases would be accepted, if they were conclusively shown by the analyses of the gases, as accounting for loss of economy. These two causes of loss are, however, usually supposed to be antagonistic to each other, that is it is supposed that both cannot take place at the same time, excessive air supply will preclude the finding of C O in the chimney gases, and the finding of C O is in itself proof of an insufficient air supply. Nevertheless Prof. Goss's chemist has found C O in the fourth test only, in which the air was in greater excess than in any other of the tests. Attempting to account for this Prof. Goss has recourse to a theory of Herr R. Ernst, that C O is formed under very high rates of combustion, "or more specifically when the temperature of the fire is above 1,800° F." We have looked up the reference to this theory given by Prof. Goss, and find it only in the shape of an editorial in "The Engineer" (London) of Aug. 4, 1893, which gives no details of the experiments upon which Herr Ernst based his theory. In the absence of the experimental proof of the theory we must decline to accept it, and in fact the editorial referred to appears to us to contain more rank heresy on the subject of combustion than we had ever before seen.

We have a theory of our own to explain the analyses given by Prof. Goss, and that is that either the sampling of the gases or the analyses were incorrect, and for proof of this we submit the following calculation: Prof. Goss correctly states that "all air admitted to the furnace in excess of that required for combustion is heated from the temperature of the atmosphere to that of the smoke box, and by this process heat is taken from the furnace." The analyses of the gases give us the data by which we can obtain the amount of air supplied to the fire per lb. of carbon. The formula is

$$\text{Lbs. of air per lb. carbon} = \frac{4}{3}\left[\frac{2(CO_2 + O) + CO}{CO_2 + CO}\right] \div 0.23.$$

Applying this formula to the analyses we obtain for the amount of air supplied to the fire per lb. of carbon in each of the four tests:

No. 1, 38.4 lbs.; No. 2, 33.5 lbs.; No. 3, 46.9 lbs.; No. 4, 102.5 lbs.

Since the ultimate analyses of the coal is not given, we cannot say accurately how much total carbon was in the coal, but if we assume that 5% of the weight of the coal was hydrogen, nitrogen and oxygen, and that the remainder of the volatile matter was carbon, we will have the percentage of total carbon in the coal nearly enough for the purposes of the calculation, as follows:

No. 1, 84.9% No. 2, 85.8% No. 3, 85.0% No. 4, 85.4%

Multiplying the weight of air per lb. of carbon by these figures we have for the weight of air per lb. coal burned:

No. 1, 32.6 lbs.; No. 2, 28.7 lbs.; No. 3, 39.9 lbs.; No. 4, 87.5 lbs.

But this calculation assumes that all the carbon in the coal was burned, whereas the fact was that a considerable portion escaped in the form of sparks, and a small portion, according to the analyses in the shape of heavy hydrocarbon. If we take as the percentage of this carbon loss the percentage of loss of heating value in the sparks, a close enough approximation, we will have for the carbon actually burned, expressed as a percentage of the total weight of coal:

No. 1, 80.6% No. 2, 78.8% No. 3. 74.8% No. 4, 69.9%

and for the weight of air supplied to the fire per lb. of coal used

No. 1, 31.0 lbs.; No. 2, 26.4 lbs.; No. 3, 35.1 lbs.; No. 4, 71.6 lbs.

The weight of gases per lb. of coal used would be the same as the weight of air plus the weight of the combustible portion of the coal which entered into the gases, or approximately,

No. 1, 31.9 lbs.; No. 2, 27.2 lbs.; No. 3, 35.9 lbs.; No. 4, 72.3 lbs.

The loss of heat in the gases passing out of the stack is the product of their weight into their average specific heat (say 0.24) into the difference between the temperature of the smoke box and that of the atmosphere (say 60°). The difference of temperature in the four tests respectively is

587°, 569°, 550° and 440° F.

Multiplying these figures by the weight of gas per pound of coal and by the specific heat we have for the heat loss, in units of heat per lb. of coal burned,

No. 1, 4,493. No. 2, 3,814. No. 3, 5,139. No. 4, 7,635.

As the total heating value per pound of dry coal was 13,000 B. T. U., these figures give as the percentage of the total heat of the coal, which was lost in the gases discharged from the stack,

No. 1, 34.6% No. 2, 29.3% No. 3. 39.5% No. 4, 58.7%

We have already found that the sum of the heat absorbed by the water in the boiler and the spark loss was

No. 1, 65.7% No. 2, 65.5% No. 3. 66.1% No. 4, 65.1%

Adding these figures together we have

No. 1, 100.3% No. 2, 94.8% No. 3. 105.6% No. 4, 123.8%

No account has been taken of loss by radiation, which, if obtained, would increase these figures. The meaning of the last figure is that without considering the losses by radiation and by imperfect combustion the heat absorbed by the boiler, that lost by unburned sparks, and that lost in the gases discharged from the stack, accounts for all the heating value of the coal and 23.8% more. The most reasonable explanation of this absurd result, it seems to us, is that there was something wrong with the analyses of the gases.

The results of these four tests, as we read them, are valuable in showing that the efficiency of this particular locomotive is reduced only from 61% to 50% by increasing the rate of combustion from 60 to 240 lbs. per sq. ft. of grate per hour, and that the whole of this loss of efficiency is due to the loss from sparks, which loss increased from 4% to 15% of the total heating value of the coal used.

It does not appear from these tests that rapidity of combustion has any bad effect upon the combustion itself, or any bad effect whatever, except that when the rate of combustion is high sparks are more apt to be driven out of the stack. There appears to us to be no reason why very rapid driving should make any difference in the economy, other than the loss by sparks, provided the grate surface is cut down proportionately to the increased rate of driving, and the thickness of the bed of fire is proportioned to the speed of the current of air passing through it. This thickness of bed is really the most important element. With a given air supply if the fire bed is too thick, carbon monoxide will be formed; if too thin, the combustion may be perfect, but there is apt to be a great excess of air, which will cause an excessive amount of heat to be carried up the stack. With a thin bed of coal and a very low draft pressure there may be perfect combustion and not too great an excess of air. With a very thick bed and with a strong draft there may also be perfect combustion and no great excess of air. Opposite conditions, thick fire bed with strong draft and thin fire bed with light draft, may produce identical results as far as economy is concerned. Whether in any particular case a high rate or a low rate of combustion should be adopted will depend not on the theoretical consideration of which will insure the most perfect combustion, but on other circumstances which relate entirely to convenience or to practice. In stationary boilers low rates of combustion may be adopted with the best results, but if a low rate means too long a fire grate for a fireman to fire properly, then a higher rate with a shorter grate should be adopted. Higher rates of combustion are adopted on locomotives than in stationary boilers, not because they give more perfect combustion, but because they cause the boiler to generate steam in sufficient quantity. Prof. Goss has shown that the spark loss limits the rate of combustion which may be used without great loss of economy. If there was any possible way of returning the sparks to the furnace, there seems to be no reason why still higher rates than any he has tried might not be adopted. In a blast furnace for making iron, as much as 15 tons of coal per hour may be burned, the total area of the zone of combustion not exceeding 30 sq. ft. This is equivalent to a rate of combustion of over 1,000 lbs. per sq. ft. of sectional area per hour, or about five times the highest rate used in locomotive boilers, and more than fifty times the usual rate in stationary boilers. If any necessity should arise for burning 1,000 lbs. of coal per sq. ft. of grate area per hour under a steam boiler it might be done without sacrifice of economy if only proper procession could be made for getting rid of the ashes and for preventing loss by sparks. High rates of combustion of themselves do not mean imperfect combustion, undue excess of air, or loss of economy, nor do they mean the reverse. Their use is therefore permissible if circumstances require.

In the case of locomotives there is an additional cause of loss of economy by high rates of combustion, besides the spark loss, and that is that these high rates require increased draft, which is only secured by increased back pressure in the cylinders of the engine. In the four tests by Prof. Goss the draft pressure was respectively 2.2, 2.5, 3.3 and 5.6 ins. of water. It is probable that indicator diagrams from the cylinders would show that the loss of power in the engine due to the increased back pressure required to provide the strong draft amounted to quite an appreciable percentage of the total power developed.

LETTERS TO THE EDITOR.

Driving Logs Upstream.

Sir: In your issue of Sept. 10 information is asked with reference to "driving" logs upstream. An old "shanty" foreman, Wm. Scott, tells me that though very unusual this has been done. His experience was on Deep River, a tributary of the Ottawa, the distance over which the logs were moved was comparatively short. A line was let down stream to which ring "dogs" were attached, two to each log, Each log butted closely to the preceding one and this log "snake" was drawn up the stream by a sort of crab capstan. The chief feature is that the current only impinges on the butt of the leading log. Assembling the "tow" is somewhat difficult as is also the withdrawing of the "ring dogs." These consist of a flat spike with a loose ring normal to the plane of the knife-shaped blade. I remain, yours, etc.

C. R. Coutlee.

Cascades Point, Quebec, Sept. 19, 1896.

A Cheap Bridge.

Sir: I send you herewith a photograph which, I think, may be of interest to your readers as an unique and efficient structure of very low cost. The severe freshet of last spring washed away the bridge over the Little Androscoggin River at Snow Falls in the town of Paris, Me., and this bridge was built by me for the town for a temporary foot bridge pending the erection of the new structure. The fir-balsam logs were cut in the adjacent woods and strung across the gorge; towers were built on each bank of hemlock logs; and cables of twisted wire fence ribbon were passed from anchorages on either bank over the towers and under pieces of iron pipe passed under the stringers. One anchorage is shown in the photograph, the wires being nailed to a timber braced under the bracket of an old boiler, while the other ends are fastened to the bottoms of tree trunks. The wires were drawn tight by means of the usual fence stretchers in use by farmers. A few old planks, which did not follow the bridge down stream made the floor, and rails were found within a few feet. I did no figuring of strains, the work being hastily contrived, but I was satisfied by seeing the bridge sustain, without noticeably deflecting, a load of a little over 500 lbs. concentrated at the center.

Temporary Foot Bridge over Little Androscoggin River, at Snow's Falls, Maine. Span between Towers, 40 ft.

The cost of this bridge was almost entirely in labor, the material, with the exception of the fence ribbon and a few pounds of nails and spikes, being picked up in the immediate vicinity, the items being as follows:

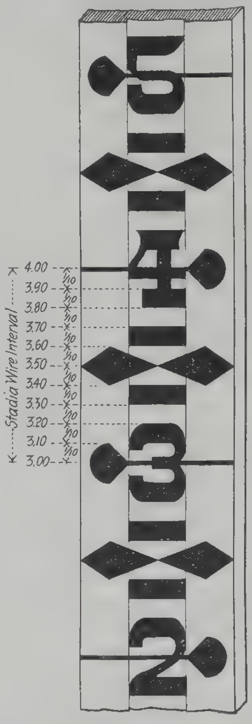
26 lbs. twisted wire fence ribbon @ .04	$1.04
1 lb. staples	.10
1 lb. 50d. spikes	.05
1 lb. 10d. nails	.04
Labor, men and oxen	$10.50
Total	$11.73

Yours very truly, Fred. J. Wood.

Snow Falls, Me., Sept. 5, 1896.

Another Stadia Rod.

Sir: I enclose herewith a sketch of a self-reading long-distance stadia rod, which I designed for use on the preliminary survey for the "Kern River & Los Angeles Electric Power Company."



Rod Marking.

Self-Reading, Long-Distance Stadia Rod, used on Preliminary Survey for the Kern River & Los Angeles Electric Power Co. Designed by Burr Bassell, C. E.

This rod was used for the entire distance of about 108 miles, crossing desert and mountains (both for stadia distances and vertical angles), and gave entire satisfaction. It cost a little less than $5 and was as serviceable at the end of the survey as at the beginning.

The criticism may be made that one cannot read close or fine enough. In actual work it was found that the rod could be easily read at long distances to 1-20 of an interval (representing 5 ft. with a 1-ft. interval, or 2½ ft. on the rod used on above-mentioned survey), and since the errors are not cumulative, but, as in leveling, tend to balance each other, very good work was done.

Permit me to call attention to the graduation, which must be studied and used to be fully appreciated.

There are no numerals excepting at the stadia wire intervals (for 100 ft.), The half intervals marked by double diamond figures are exceptionally clear to read at long range. The circular dart at each numeral alternate to right and left side of rod—the right hand being opposite even numerals and the left hand opposite the odd. This lessens the liability to err in reading, when rod is partially hid from view.

I am well aware that almost every engineer has his "pet rod." If you think this worthy the space in your valuable paper, you are welcome to use it. I claim the following for this rod: (1) Simplicity and ease of reading. (2) Cheapness and facility of transportation over rough mountainous country. (3) Durability.

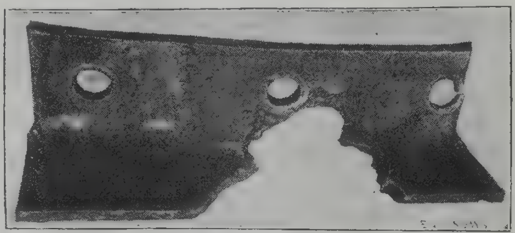
Yours truly, Burr Bassell.

Los Angeles, Cal., Aug. 31, 1896.

A Bridge Angle Iron Melted by Lightning.

Sir: I send you herewith a photograph of a piece of angle iron recently taken from a railway bridge over a street in Lowell, Mass. It was evidently melted by lightning, although no one knew that the bridge had been struck until the damage was discovered by the bridge inspector in making his periodical examination.

The bridge is in one of the freight yards at Lowell and a switchman is stationed very near one end of it, but he was unaware that lightning had visited his vicinity. This bridge carries five tracks on four pony trusses. Four of these tracks are used by regular passenger and freight trains and one, where the damage occurred, for yard shifting only.



A Bridge Angle-Iron Melted by Lightning.

The angle iron in question was in the top flange of a floor beam under this side track; the flange being made up of two 3½ × 3½ × ⅜-in. angles. The rail crossed the floor beam directly over the place burned out and about 2¼ ins. above it. Half of the rail base for a space of about 6 ins. and part of the thickness of the web was melted, a hole about 4 ins. in diameter was burned through the 1-in. board floor and the hard pine tie lying against the edge of the floor beam flange was charred into about 1 in. The paint was burned off clean over a space about 1 ft. in diameter below the burned angle, but was not affected on the other side of the floor beam web. There was no further trace of the current.

A double track electric line passes under this bridge with overhead trolley wire attached to the ironwork by insulated connections. One of these wires passes about 6 ft. from the point of the bridge attacked, but there is no evidence of the current traveling to the wire and there is no record in the office of the electric road of any disturbance to the wires or the insulation.

Yours truly, J. P. Snow,
Bridge Engineer, Boston & Maine R. R.

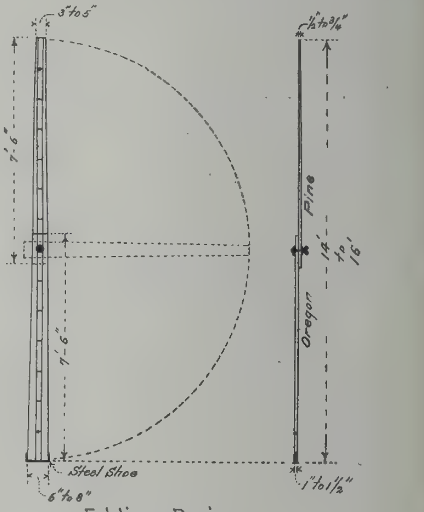
Boston, Sept. 5, 1896.

Subjects for Theses on Municipal Engineering.

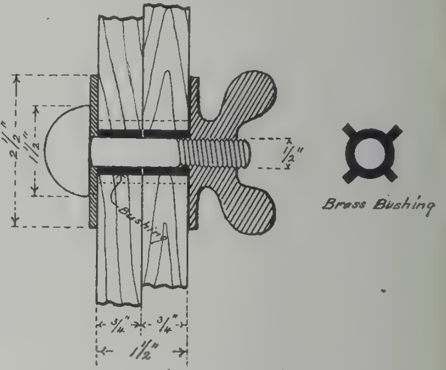
Sir: Will you kindly suggest some lines of investigation in matters pertaining to municipal or sanitary engineering that would furnish subjects for theses? Subjects that advanced students might deal with in a manner to be of value to the profession, in the time usually allowed for thesis work in the best colleges of civil engineering.

Yours, etc., X. Y. Z.

Ithaca, N. Y., Aug. 31, 1896.



Folding Device.



Details of Clamp Screw.

Interval between digits 1 foot, or distance intercepted by stadia wires with the rod 100 feet from instrument.
Vertical thickness of figures and bars 1/10 the interval between digits.
Width of digits 2/10 or 3/10 of the interval.
Height of digits 4/10 of the interval.

Details of Stadia Rod.

(There is no end to the list of municipal and sanitary engineering subjects which need careful investigation, although it may not be easy to name many which are in every way suitable to college thesis work. The truth of the matter is, though, that more depends upon the way the college student handles his subject than upon what he chooses. We give a few subjects, more in the way of suggesting other, allied ones, or modifications of these, than with the idea of finalities, as follows:

(1) Sewer flushing, with special reference to the efficiency of automatic flush tanks.

(2) Paving materials: Not an attempt to cover

the whole subject, but a careful study of some phase of it, or some particular material, based on experiments by the author as well as the results of actual practice.

(3) Water rates, including the proper method of distributing the cost of water between private consumers and the general public.

(4) Dams and reservoir failures; actual incidents with their causes and lessons.

(5) Studies of actual typhoid epidemics in relation to water, milk and food supplies. As the epidemics taken up should be such as had not been carefully investigated, and would need to be studied while actually in progress, the availability of this subject would be uncertain in any particular case.—Ed.)

Testing Steel Tapes.

Sir: Kindly state the standard temperature and pull at which steel tapes (100 ft.) are correct; whether the tape is suspended or laid on a level surface; the practice of the U. S. Government in these particulars; and the standard temperature at which steel bridges are laid out in the shops or at which they have their correct length.

Respectfully, Oscar Erlandsen,
Assoc. M. Am. Soc. C. E.

136 Liberty St., New York, Sept. 15, 1896.

(By applying to the U. S. Coast and Geodetic Survey, Washington, D. C., our correspondent can obtain a copy of Bulletin No. 15, issued in 1889, describing the U. S. Bench Standard, by which the errors of tapes are determined. It is there explained that an iron bar, 100 ft. long, has been selected in preference to a wall standard, as in the latter case the effect of temperature on the wall is difficult to ascertain. The material in the tape and bar is also so nearly identical that temperature observations are almost, if not quite, unnecessary. One end of the tape is secured to this bar and laid out flat upon the bar, so that it quickly reaches the same temperature. The tape is then stretched by a spring-balance, sensitive to a half-ounce, and the usual pull is 12 lbs., and this pull is stated in the certificate given by the Bureau. Inserted in the bar are two parallel series of German silver plugs, on the polished surface of which the graduation is marked in fine lines. One series of plugs carries the graduation in yards, and is intended to be standard at 62° Fahr.; and the other series carries meters, standard at 32° Fahr., or 0° Centigrade. The correction to the tape is read by a finely divided scale; sometimes with a low-power microscope, when the graduation on the tape is sufficiently fine to justify its use. The charge for testing a tape at Washington is $25. As to the standard temperature for bridge work, we assume that the U. S. standard is generally employed; but we would ask for a reply to this question from those more familiar with current practice in bridge shops. In the published transactions of the Ohio Society of Surveyors and Civil Engineers, for 1893 and 1894, will be found some very useful matter upon the subject of testing steel tapes, including valuable communications upon this subject from Prof. T. C. Mendenhall and the late J. E. Hilgard, each of whom have been at the head of the U. S. Coast and Geodetic Survey.—Ed.)

The Link Movement Engine.

Sir: The description of Chapman's link movement engine, copied from "The Engineer" (London), in your issue of Aug. 13, p. 101, contains a surprising number of misstatements, considering its brevity.

Taking them in order; the pistons do not "move diagonally" but perpendicularly to each other. The crossheads and not the pistons "cross and recross midway at every stroke," and the crossheads and not the pistons are connected by a link, which, by the way, is not half the length of each piston but of their stroke. "A pin at each end of the link passing through the crossheads" does not "form the respective cranks." The statement that "circular motions cause the rotation of the shafts" is probably correct, though its connection with the reduction to a minimum of the pressure on the slippers is not very clear.

The "known geometrical fact" is correctly stated, but is perfectly irrelevant. It formed the basis of an old and now discarded parallel motion, but Mr. Chapman's engine does not utilize this principle in any way whatever. On the contrary, the principle of the "link movement" is that of the ordinary trammel for drawing ellipses. If the extremities of a straight line move in lines at right angles to each other then all points on the line will describe ellipses and the point at the center of the line will describe an ellipse of no eccentricity, or, in other words, a circle. Any of your "readers accustomed to geometrical work will see without further description" that this is not a parallel motion of any sort.

Fig. 1 does not "show the pistons (or either of them) at the ends of their strokes." They cannot both be at the ends of their strokes at the same time. It is true that "it is not possible to dispense with guides," but the Chicago nominations have as much to do with it as the reason which is given.

Finally, the link, now called a "flying crank," whatever that may be, cannot possibly "act like an ordinary drag link." The writer kindly says in conclusion that "this seems to be a very meritorious attempt to solve a difficult problem." Difficult attempt to solve a meritorious problem would be nearer the mark and more in keeping with some previous statements. The problem of driving a crank by two cylinders at right angles to each other is simple and common enough. It has been made difficult by the unusual method adopted for its solution, which seems much more ingenious than useful. A still more difficult problem would be to crowd a greater number of bulls and blunders into a mechanical description of equal length. In a somewhat extensive reading of engineering literature I have never seen anything approaching this except from "The Engineer." It is a gem in its way.

New York, Aug. 22, 1896. H. W. B.

Mr. Donaldson's Proposed Standard Specification for Portland Cement.

Sir: In your issue of Sept. 10 I read the reply Mr. W. J. Donaldson makes to my criticism of his specification for Portland cement. In view of the series of errors he makes in quoting me and making me say directly the reverse from what your publication shows I did say in the clearest of English, I must trespass again on your valuable space for the purpose of correcting these errors.

I suggested no new specification, but gave to the engineering community, through your journal, a summary of what the leading engineers, chemists and scientists of the world had contributed to this subject, believing that in a matter such as the use of cement, which certainly is one wherein the questions of permanence and endurance enter, that the experience of years, and the concentrated wisdom of great men in the field, should carry weight and be of value to the profession.

In the conclusion of his argument for the adoption by the government of his new specification, Mr. Donaldson says:

> In conclusion we have only stated facts as they now exist and urged the adoption of one standard and that high in the specifications for quality, together with a uniform and specific method of testing which shall prove advantageous to the United States Government.

He says further in your issue of Sept. 10:

> It is a well-known fact that the recommendations of the Committee of the American Society of Civil Engineers are indefinite and altogether incapable of producing uniform results. The requirements are on the whole too low, and inadequate, which allow of second grade cements going into work where the highest grade Portland cements are intended.

Finally, in referring to the specifications cited by me on the subject of tensile strains, Mr. Donaldson says:

> The majority are old specifications whose requirements were favored some ten years ago when Portland cement, as an industry, was still in its infancy.

Now, from the above, it is certainly a fair criticism to say that Mr. Donaldson is "going it alone" in the matter of specifications. For a man, who proposes "one standard, and that a high one;" who objects to the American Society's specifications on account of "indefiniteness" and "inadequacy," and who finally has the hardihood to state that "ten years ago the Portland cement industry was still in its infancy," certainly lays himself open to comment on the boldness of his unsupported statements.

Will any engineer of standing, such as those who have constructed the monumental and colossal bridges, buildings, reservoirs, aqueducts and tunnels, railways and other public works done in the United States since June 21, 1885, the date of the American Society's specification. admit what Mr. Donaldson says of its requirements? Is it possible that all this work has been badly done with cement of "second grade," though done by such distinguished engineers as Fteley, Morrison, MacDonald, T. C. Clarke, Bogart, Herschel, Sayre, Becker, Wainwright, Burbank, John A. Wilson, Joseph M. Wilson, Eads, Stedman, Sooysmith, Craven, Nichols, Rodd, W. H. Brown. Douglas, Gowan, Boller, Richards, as well as by hundreds of other well-known engineers? It cannot be the case. but it IS possible that Mr. Donaldson may be wrong in this, as well as in his statement as to the Portland cement industry, which he says "was still in its infancy" ten years ago, shortly before the time Mr. Donaldson appeared upon the scene as a cement dealer, though the works with which he is connected are only about four or five years old. As against Vicat, who wrote a book of 300 pages on the subject of limes and natural and artificial cements, published in London in 1837; C. W. Pasley, C. B., whose work was published in London in 1838; against the patents granted to Aspdin in 1824; Frost in 1822; against Reid, Faija and other early writers; against that long series of scientific papers on Portland cement, in the proceedings of the Institution of Civil Engineers, London; the American Society of Civil Engineers; the French Annales des Ponts et Chaussees; the German Cement Makers' Association Proceedings, beginning with John Grant's paper of 1865 and continued down to the present day, it is futile to talk as a scientific proposition of the Portland cement industry being in its infancy "ten years ago." As a commercial proposition it is equally preposterous, for the reports of the Bureau of Statistics of the Treasury show that in 1886 915,255 barrels of Portland cement were imported into the United States, while in 1887 and 1888 the figures were respectively 1,514,095 and 1,835,504 barrels, and the report of the German Cement Makers' Association for 1885 shows a production of 4,700,000 barrels, and Candlot, writing in Paris in 1891, puts the French product prior to 1880 at 700,000 barrels per annum, and the German production for 1888 at 6,000,000 barrels; the "Revue du Genie," Jan., Feb., 1888, puts the English product for 1887 at 7,500,000 barrels, and Rothwell in his book on the Mining Industry in the United States puts the American product of Portland cement for 1886 and 1887 at 150,000 and 250,000 barrels respectively. Infantile figures these!

So much for the "infancy of the Portland cement industry ten years ago." Mr. Donaldson's statement reminds one of the fly who, alighting on the wheel of a moving vehicle, remarked ecstatically, "See how I make it go." The industry was going when he came into it, the established specifications were in successful use then, and it would seem that to reverse established standards, not of one country, but of the civilized world, because of some "improvements made in grinding machinery and in modes of burning" only a few years in use is asking too much, especially as against the long time records of cement made under well-known methods.

From the above it will certainly appear that Mr. Donaldson is hardly the proper party to make a new specification, or even, as he now says, to "present the subject in the light of suggestion and thereby open up scientific discussion." Certainly if there were a doubt on this question, what follows will effectually remove it.

I criticised Mr. Donaldson's specification on four principal elements—chemical composition, fineness, checking and cracking, and tensile strength.

It must be admitted that if, in so serious a matter as the chemical composition of a cement, the proposer of a new specification fails, the bulk of what follows is of no use because the chemical composition would govern largely the other elements of the specification, and especially those relating to specific gravity, checking and cracking, and tensile strength. When, therefore, in reply to sixteen (16) authorities, viz., Candlot, Le Chatelier, Feret, de Rochemont, Tetmajer, Preussing, Redgrave, W. F. Reid, Henry Reid, Faija, Carey, Collins, DeSmedt. Spaulding, Jameson and Gilmore, giving analyses of nearly two hundred (200) brands of Portland cements of France, Belgium, Germany, England and America, Mr. Donaldson states that he "bases his requirements on the average results of the analyses of the best German, French and American brands, with a few Belgian and English cements," and fails to state the brands used in such analyses, the place of analysis, the time of analysis, and the chemist making such analyses, his case certainly falls, and he is right in stating and admitting what he does in reply to the writer and Professor Newberry, i. e., "The criticism on chemical composition appears to be well founded." So much therefore for this basic and most important branch of Mr. Donaldson's specification.

As to the question of fineness, I named 21 different specifications, embracing the official specifications of Belgium, Germany, Switzerland, France, Roumania, England, the United States, the recommendations of the American Society of Civil Engineers, and a number of other specifications in this country, against which Mr. Donaldson cites Henry Faija in his book on "Portland Cement for Users," dated 1890, who recommends fine grinding; but this same Henry Faija, whom I quoted under date of August 2, 1893 (three years later), recommends in his paper read before the World's Fair Congress, 8% on a 2,500 mesh sieve. On this branch of the case, certainly I am right when I say that Mr. Donaldson is arrayed against the world's scientific opinion.

Mr. Donaldson's specification on the subject of checking and cracking requires that a "cake of neat cement, after having set hard, is to be immersed in water at 212° F. and allowed to remain in the water at that temperature from 24 to 36 hours." This I interpret, and this I think can hardly be gainsaid, as a boiling test. In answering, I state: "The last report of the Committee of the German Cement Makers' Association, presented at the 1896 meeting on this subject, asks until 1898 to report, and meanwhile the normal cold water tests remain unassailed."

> Germany: After three years' discussion, the boiling test was finally reported against at the session of 1893, by the German Cement Association, operating in conjunction with the Prussian Minister (Gary's paper, World's Fair Congress, Aug. 1893)."
>
> French Government: Conference of engineers Ponts et Chaussees Cahier Guillan, Service de la Marine, Service de Colonie. None of these contain boiling tests. The French Government report is above referred to.

England: Faija's paper, World's Fair Congress, Aug. 2, 1893, Trans. Am. Soc. C. E., Oct. 1893; Trans. Am. Soc. C. E., Oct. 1893, recommends steaming tests only, and immersion at 116° and requires no boiling test, which he admits he has abandoned as unreliable, though first proposed by himself.

United States: U. S. Govt., District of Columbia specification, 1896, abandons boiling test. F. H. Lewis (Booth, Garret & Blair testing laboratory), Philadelphia, Proc. Am. Soc. C. E., Vol. XXXII., page 321, abandons boiling as "unreliable in indicating quality of cement." Am. Soc. C. E. specification recommends cold water and air tests only.

In reply to this Mr. Donaldson says: "Upon the question of hot test take up the first country, Germany. He (Mr. Lesley) admits that investigations are still being made on its reliability, and in the meantime the test is still made." Mr. Donaldson also cites what I quoted of Mr. Faija, and says "he immerses and steams in water at 116°, thereby showing that he must still have faith in the hot water test;" and finally Mr. Donaldson says, "from a brief summary of the above, it will be seen that the German, French and English authorities still adhere to the hot test, while the only two doubtful authorities are quoted for the United States."

Now the issue between Mr. Donaldson and myself is on the "boiling test," which he specifically recommends and nothing else, and a reading of what I wrote will show that the authorities I quoted are against that test absolutely and unequivocally.

As to the change in the District of Columbia specification, the authority for which Mr. Donaldson asks, I can only reply that the specification is signed, J. W. Ross, George Truesdell, Charles F. Powell, Commissioners, and of these, Mr. Powell is Engineer Commissioner. As this change was made after Mr. Donaldson's cement was rejected on the 1895 specifications requiring the boiling test, it would seem possible that he might have the latest information in that quarter.

As to the attempt to belittle the scientific reputation of Mr. F. H. Lewis, the well-known testing expert, I will say that if Mr. Donaldson had read Proc. Engineer's Club of Philadelphia, Vol. XI., No. 5, he would have found a second paper on cement by the writer mentioned, and if he had examined "Municipal Engineering" for August, 1896, he would also have discovered a controversial discussion between Mr. Lewis' firm and a Mr. W. J. Donaldson, in which Mr. Lewis' standing certainly did not suffer.

On the question of tensile strain, I cited the official specifications of France, Russia, Belgium, England, Germany and the Am. Soc. C. E. I also cited 21 specifications of leading engineers in this country, some requiring high and some low tensile strains, as mere indications of what leading authorities considered a specification should be. In reply to this, Mr. Donaldson, without citing a single authority, says broadly that "the majority are old specifications whose requirements were favored some 10 years ago, when Portland cement was an industry still in its infancy."

The specifications cited by me are all public and open to Mr. Donaldson's inspection, and it is only necessary to say that instead of "the majority being old ones" and "favored ten years ago," they are, with but possibly a single exception, in use at the present time or within at least two years, and by such engineers as Fteley, of the New York Aqueduct; Brown, of the Pennsylvania Railroad; Sayre, of the Lehigh Valley Railroad; Katte, of the New York Central Railroad; T. C. Clarke, of the Third Ave. Bridge; McNulty, of the Metropolitan Street Railway, New York; and a number of other equally distinguished engineers. Not a single specification is refuted by Mr. Donaldson, nor its accuracy questioned, nor a word of proof given as to the statement that the specifications are "old," but against this mass of testimony he states that "in the City of Philadelphia alone, five of the leading architects are using large quantities of Portland cement under specifications equally as high as those quoted by the writer," and still he fails to mention any single one of the architects in question, by name, or the work on which the cement is being used.

This sort of a reply is hardly sufficient to overthrow the mass of evidence I have adduced, and is on a par with his other statement as to the long time tests on the New York Aqueduct being on one brand of cement "exclusively." A glance at Mr. McCulloh's paper on the Sodom Dam ("Proc. Am. Soc. C. E.," April 5, 1893), would have shown him the absolute inaccuracy of such a statement, while an examination of the official records from which Mr. McCulloh's figures were taken, would have shown an enumeration of some 30 odd brands of Portland cement.

In conclusion, I am asked by Mr. Donaldson to state in what manner the "crude specifications" would prove harmful to "inexperienced engineers and architects." Having, I think, shown that the specification is crude and ill-digested, inasmuch as it is admittedly wrong chemically, and fails to find scientific support for its other members against the authorities cited by me, I can safely say that with the experience of the Aberdeen breakwater and the Saint Nazaire Bridge, in France, before us, that if any engineer were to use in salt water a cement containing 66% lime, and 2% sulphuric acid and 3½% magnesia, he would under Feret's experiments, as well as the papers describing the failures above mentioned, be in danger of having his work fail, especially as Mr. Donaldson does not in treating the question of sulphuric acid draw the proper distinction between salt and fresh water work.

Now engineers and architects, being professional men, stake their name, honor and reputation on every piece of work they do. Such a failure as I have mentioned would mean to an engineer or architect the loss of those things which are dearer than life itself. I think this makes it clear how a "crude" specification may do great harm.

Respectfully,
Robert W. Lesley, Assoc. Am. Soc. C. E.
22 South 15th St., Philadelphia, Pa., Sept. 21, 1896.

THE LARGEST BUILDING EVER MOVED IN THIS country was a freight warehouse of the B. & O. R. R. in Baltimore, which was moved Sept. 8 to 12. The building is 440 ft. long, 120 ft. wide and 60 ft. high. It is a wood and iron structure and was moved to make room for a new dock. The work consumed 5½ days. The building contained a great quantity of freight, among which was 3,000 cases of china and crockery, but not a dish was cracked in the moving. The men were engaged five weeks making preparations for the move. On top of the old and the new foundations were placed the sills or tracks upon which the building was to run. These tracks numbered 40, each consisting of two 6 × 12-in. timbers. On top of these were placed the 1,000 rollers, each a piece of 5-in. pipe 3 ft. in length. There were 25 rollers to each of the 40 tracks. Between the top of the rollers and the floor beams of the building were arranged more of the 6 × 12-in. timbers. In all 6,600 of the 6 × 12-in. timbers were used, each about 30 ft. long. The 255 wooden pallars which supported the warehouse were then sawed away and the structure rested upon the rollers. Along one side of the building were placed 40 5-ton screw jacks. They were braced against a railroad track, an adjoining warehouse and the tracks upon which the rollers ran. Two men stood at each jack. At a given signal the men responded with military precision, and each jack was given a quarter of a turn, moving the great building a fraction of an inch, Afterward the progress averaged 2 ft. an hour for 5½ days. The structure arrived at its new foundation without a strained timber or a bolt. The jacks were again used in raising the warehouse enough to allow the removal of the jacks, after which it was lowered to the new foundations. The structure cost $35,000 ten years ago, and it cost $15,000 to make the removal.

AN IMPROVED HOWELL AUTOMOBILE TORPEDO has been lately tested by the U. S. Government and the results are highly satisfactory. The new torpedo is 14½ ft. long, 17 ins. in greatest diameter, has a launching weight of 1,130 lbs., with a reserve buoyancy of 20 lbs., and an immersed displacement in sea water of 1,150 lbs. It carries a charge of 174 lbs. of gun cotton. The mean speed over a range of 400 yds. is 33 knots; over a 600-yd. range, 30 knots, and over 800 yds., 28.5 knots. The extreme effective range for regular service is 1,000 yds. The older Howell torpedo was 11 ft. 2 ins. long, and 14 ins. in diameter, and had an effective range of 600 yds., with a speed of 18 knots. It carried only 82.75 lbs. of gun cotton. Instead of being propelled by compressed air stored in the torpedo itself, as in other types, the Howell torpedo has a turbine motor attached to the launching tube, which gives an exceedingly high speed to a heavy steel fly-wheel within the tube; the stored-up energy of this fly-wheel is then transmitted to two propellers by gearing. The torpedo is launched by indirect gun powder impulse, with the fly-wheel revolving at a speed of about 10,000 revolutions per minute. Out of 346 shots, with the launching tube 2½ ft. above the water, there were 332 hits, 10 misses, and 4 accidents; with the tube 9½ ft. above the water there were 63 hits out of 69 shots. The target was a rectangle 21 yds. long by 1 yd. wide, 8 ft. below the water surface.

◆

THE ARMORED CRUISER "BROOKLYN" is officially declared to have made 21.9117 knots per hour as the average of her late trial run, and the Navy Department awards the builders, the Cramps, of Philadelphia, a premium of $350,000. The contract speed was 20 knots. The Inspection Board also says that the weights are in accordance with the contract, the machinery performance was satisfactory and her steering qualities in smooth water were excellent. Owing to the absence of heavy weather during her trial trip the behavior of the ship as respects rolling and pitching was not tested.

◆

A NEW TRANSATLANTIC STEAMSHIP LINE, formed by the consolidation of the line of the Wilson Bros., at Hull, England, and the Leyland-Furness line, of London, is announced to run a weekly service between Brooklyn and London, and also between Boston and London. Contracts for five new vessels have been given out, to be ready for service next June. They will have a cargo capacity of 8,000 tons, and accommodations for 80 saloon passengers. The speed will be 14 knots per hour.

◆

AN ARMOR-PIERCING PROJECTILE designed by Isaac G. Johnson & Co., of Spuyten Duyvil, has again been successfully tested at Indian Head upon a 10-in. rerolled Harveyized steel plate made by Carnegie & Co. for the Russian government. A 6-in. projectile of solid steel was used, hardened by a special process and capped by soft steel. The projectile weighed 100 lbs., including the 5-lb. cap, and smokeless powder was employed to impart an initial velocity of 2,540 ft. sec. The projectile went clear through the 10-in. plate, through 12 ins. of oak and three steel plates, 7-16-in. thick each, and 8 ft. into the dirt back of the target. The cap alone was seriously injured, the shot being almost intact when dug out of the earth.

◆

THE DES MOINES, IA., WATER-WORKS are likely to be purchased by the city from the private company which owns them. The city has offered $800,000 for the works. Litigation between the city and the company has been in progress for some time.

COMPRESSED-AIR PLANT ON THE CONSTRUCTION OF THE JEROME PARK RESERVOIR.

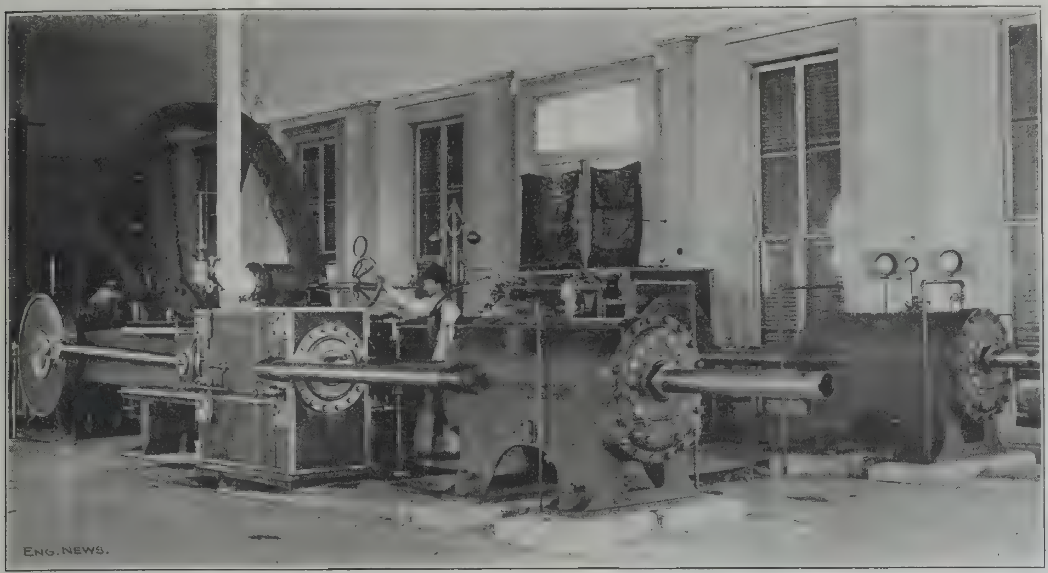

FIG. 1.—AIR COMPRESSING PLANT FOR THE WORK ON THE JEROME PARK RESERVOIR.

The use of compressed air for power purposes and power transmission has had a very great and comprehensive growth within the past few years, and one of the most recent and interesting applications of this power is on the extensive contract work for the construction of the Jerome Park reservoir, for the water supply system of New York city. As the contract amounts to nearly $5,500,000, and will extend over about seven years, there was ample reason for carefully considering the comparative advantages and economy of different methods of supplying power for the drills, hoists, pumps, etc., to be used on the work, and as a result of this investigation it was decided to use compressed air, distributed to all parts of the work by pipe lines from a central power plant. This plant is operated by one engineman and one fireman. The main pipe lines will remain practically permanent during the work, the branches being shifted, and extended as required by the progress made in excavation. This system will undoubtedly effect a considerable saving in fuel and labor expenses as compared with the more common methods.

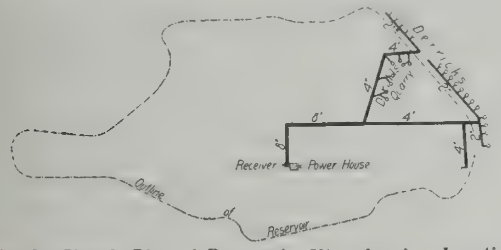

Fig. 2.—Sketch Plan of Reservoir Site, showing Location of Power House, Transmission Pipes and Working Plant.

On such construction work the general practice is to use steam power, with separate boilers for each one or two hoists, and other boilers near groups of drills. This practice is necessarily wasteful in fuel, as the amount of fuel used is excessive, the boilers not being adapted for or worked with a view to economical consumption, and much fuel being burned without doing any work during dinner hours and when the machines are stopped for any cause, while leaky joints and condensation in the long lines of pipes always cause considerable waste and trouble. Besides this a separate attendant is required for every boiler.

The Jerome Park reservoir, where this compressed air plant has been installed, was described in our issue of July 18, 1895. It is situated near Van Cortlandt Park, on the New York & Putnam Division of the New York Central R. R., about 11 miles from the Grand Central Station on 42d St., and 5 miles north of the Harlem River. It will cover about 300 acres of land and will have a capacity of 2,000,000,000 gallons. The construction will require about 4,000,000 cu. yds. of earth excavation, 3,200,000 cu. yds. of rock excavation, 150,000 cu. yds. of concrete masonry, 82,000 cu. yds. of brick masonry, 113,000 cu. yds. of rubble masonry and 250,000 sq. yds. of rubble masonry facework. The masonry includes heavy core walls for the embankments. The bids for the work ranged from about $5,000,000 to $13,000,000, and the contract was awarded in August, 1895, to Mr. John B. McDonald, of Baltimore, Md., and New York city, at $5,473,060. Preparations for commencing the work were at once started, and the work is now in active progress. At the present time about 550 men are at work, while the plant includes 8 narrow gage contractors' steam locomotives, 2 steam shovels, 18 derrick hoists, 10 drills and a number of wagons, teams, dump cars, etc. Besides this, offices, living quarters, stables and stores of all kinds of material and supplies have been established, as the work will last for about seven years, the date set for the completion of the contract being Nov. 1, 1902.

The contract for the air compressing plant was placed by Mr. McDonald with the Ingersoll-Sergeant Drill Co., of New York city, and this has now been installed and put in operation, having been started on May 14. For a power house, one of the large buildings of the club at the old Jerome Park racecourse is used; the building having been removed bodily to a convenient situation. In this are installed a cross-compound Corliss engine of 600-HP., with a compressing cylinder behind each of the steam cylinders. The engine drives a flywheel 25 ft. diameter, weighing 50,000 lbs., mounted on a shaft 14 ins. diameter, the shaft having an eccentric keyed on each side of the wheel and being driven by means of a crank disk at each end. The main shaft bearings are 14 × 26 ins. The steam cylinders are 24 × 48 ins. and 44 × 48 ins.; while the air cylinders are 24¼ × 48 ins. The cylinders are 6 ft. apart, longitudinally, and 14 ft. c. to c. transversely. The walls of the air cylinders are cooled by water jackets. The compressor is of the company's standard design, which is probably familiar to most of our readers. The air enters the cylinder through a hollow tail-rod, and the piston has an annular disk valve in each face, the space between the open valve and its seat being about ¼-in. On the forward stroke the front inlet valve is closed and the air in front of the piston is forced through the front discharge valves as soon as the cylinder pressure exceeds the receiver pressure, while at the same time air is passing through the tail-rod and open rear valve into the space behind the piston. On the return stroke the rear inlet valve is closed and the air is forced through the rear discharge valves, while the air entering through the tail-rod passes through the open inlet valve in the front face of the piston and fills the forward end of the cylinder. This arrangement was shown and described in detail in our issue of Sept. 27, 1890. Each air cylinder is also fitted with a regulator or loaded relief valve by which the load is thrown off when the normal receiver pressure is exceeded owing to the air not being used. The normal pressure in this case is 75 lbs., and when it rises to 80 lbs. a passage is opened connecting both ends of the cylinder, so that the piston has an equal air pressure on both sides, both inlet valves being thus kept closed and the piston moving to and fro without doing any work. When the air pressure has fallen a trifle below 80 lbs. the regulator closes, and compression is then resumed. This device was fully illustrated and described in our issue of March 28, 1891. The cut-off of the steam cylinders is regulated automatically by the load, as in all Corliss engines. From the compressor cylinders the air passes to the receiver, which is a riveted steel cylinder or tank 5 ft. 6 ins. diameter and 18 ft. long, placed just outside the engine house.

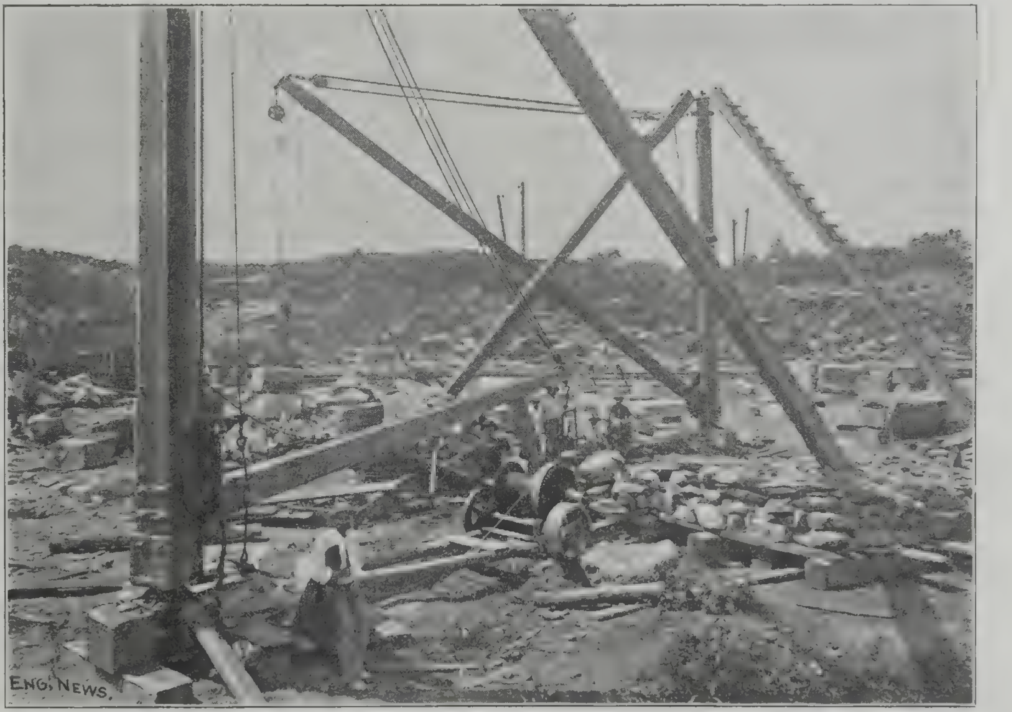

FIG. 3.—GROUP OF DERRICKS OPERATED BY COMPRESSED AIR.

The engine is intended to work as a condensing engine, but is not being so worked at present, and the connecting rod to the rocking lever of the condenser pump is disconnected. The reason for this is that there is not now a supply of water available for condensing purposes, but, of course, the engine cannot meanwhile work so economically in fuel consumption. The water for the boiler is taken from a well sunk near the engine house and a reservoir for the condensing water has been built. Steam is supplied by a single water-tube boiler made by the Hogan Boiler Co., of Middletown, N. Y., the boiler having three furnaces. The boiler is rated at 250 HP., and carries a pressure of 120 lbs. The entire power plant is handled by one engineman and one fireman. The engine and compressor were built at the works of the Ingersoll-Sergeant Drill Co., at Easton, Pa. This plant, shown in Fig 1, was started up on May 14, and later on, when a larger force is at work on the reservoir, it is intended to put in a duplicate plant, working the air cylinders compound.

Fig. 2 is a plan of the work, with an outline of the boundaries of the reservoir, and showing the positions of the pipe line, drills, hoists, etc., as at present existing. From the receiver an 8-in. pipe extends for a distance of 1,500 ft., and is followed by two main lines of 4-in. pipe, from which again run 2-in. pipes aggregating about 2,000 ft. in length. The branch pipes to the machines are 1½ ins. diameter, this being the smallest size used. The aggregate length of the piping system is now about 6,300 ft. Another 8-in. main is intended to be laid later, in a direction opposite to that taken by the present 8-in. main. All the pipe has screwed joints. There is one reheater on the 4-in. pipe line, this being of the Sergeant pattern, described in our issue of May 9, 1895. The heater is a truncated cone 3 ft. 6 in. in diameter at the base and 4 ft. 6 ins. high, the center of which forms a stove; the air enters at the top and passes down over the heating surface, the volume of air space increasing as the air expands, so that the velocity and friction remain practically constant. The use of this reheater is said to increase the efficiency 33% over work done by the same volume of air used cold. The air pressure is designed to be 75 lbs. per sq. in. at the compressor and 70 lbs. at the tools.

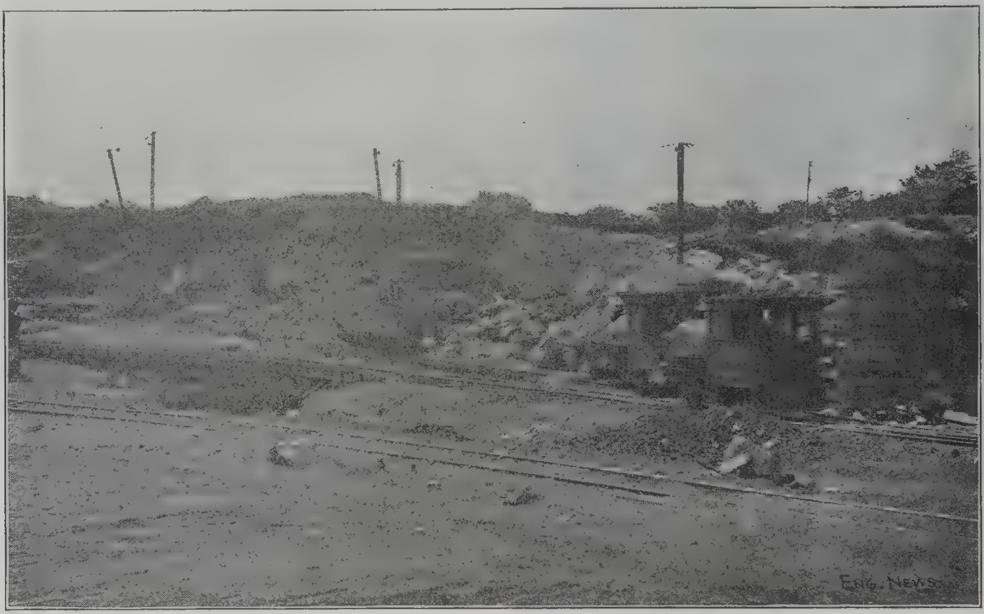

FIG. 4.—EXCAVATION AND LOADING OF ROCK BY COMPRESSED AIR PLANT.

There are now in use 10 drills, 18 derrick hoists and 2 pumps. The drills are of the well-known Ingersoll-Sergeant make. The hoisting engines are of the Lidgerwood make, with two cylinders 7 × 10 ins. and double drums. In the building of the masonry core walls for the embankments a row of derricks is erected, each derrick being operated by a hoisting engine, but the booms are swung by hand by means of guy ropes. The masts and booms are sticks 14 × 14 ins., the masts being 65 ft. long, and the booms are 62 ft. long. The derricks have a lift of 57 ft., a working radius of 118 ft., and a hoisting capacity of 10 tons. The pumps are small horizontal pumps placed in the trenches for the core wall foundations.

Figs. 3 and 4 show two views of the work now in progress. The derricks are all operated by compressed air, and the rock excavation shown was effected by groups of drills operated by air. For photographs and other information used in this article we are indebted to the Ingersoll-Sergeant Drill Co., and to Mr. Henry B. Reed, C. E., who is superintendent for Mr. McDonald, the contractor.

THE EFFECT OF HIGH RATES OF COMBUSTION UPON THE EFFICIENCY OF LOCOMOTIVE BOILERS.*

By Prof. W. F. M. Goss.**

The experiments with which this paper is concerned were carried out a few months ago in the locomotive laboratory of Purdue University.

The boiler of any given locomotive is most efficient when worked at the lowest power practicable; that is, when the rate of combustion in its firebox is minimum. For the development of a higher power, the rate of combustion must be increased, and, as a result, the efficiency of the boiler is lowered.

The relation between the rate of combustion and the weight of water per pound of coal for the Purdue locomotive "Schenectady," while using Brazil block coal, is shown by Fig. 1. From this diagram it appears that when coal is burned at the rate of 50 lbs. per sq. ft. of grate per hour, 8 lbs. of water are evaporated for each pound of coal; while if the rate of combustion is increased to 180 lbs. per sq. ft. of grate, the evaporation falls to about 5 lbs.—a loss in water evaporated per pound of coal of nearly 40%. This loss may be due to a failure of the heating surfaces to absorb properly the increased volume of heat passing over them, or to the imperfect combustion of the fuel upon the grate, or it may be due to a combination of these causes.

That a portion of the loss occurs along the heating surfaces hardly admits of question, since it is well known that any increase in the rate of combustion results in a rise in the temperature of the smokebox gases; but whether, under ordinary conditions, any considerable portion of the loss shown by Fig. 1 is due to imperfect combustion, has not been demonstrated, and it is this question especially that the present paper attempts to treat.

The importance of the subject is emphasized by the varying practice of locomotive designers, who, in some cases, have so designed large boilers as to allow a large grate; while in others they have been content to use a grate of moderate size, upon which they have forced the combustion beyond limits which had hitherto been customary.

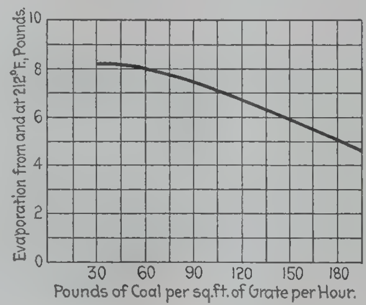

Fig. 1.—Relation between Rate of Combustion and Weight of Water Evaporated per Pound of Coal in Locomotive "Schenectady."

A separation of the losses which may occur at the grate from those which take place along the heating surface cannot be accomplished by boiler tests alone, because the results of such tests give the combined effect of both these losses. There are two variables involved, and in order that either may be determined one must be given a constant value. In the tests described, action along the heating surface was maintained constant, while conditions at the grate were varied.

As a preliminary step, a number of tests were outlined in which the total weight of fuel fired was to be constant throughout the series, while the rate of combustion was to be made different for each test by changing the area of the grate. It is evident that if the action at the grate were equally efficient during the several tests—that is; for different rates of combustion—this provision would cause the same volume of heat to pass over the heating surfaces of the boiler, and hence would produce the same evaporation and the same smokebox temperature. If, on the other hand, the combustion should prove less efficient for any one test than for others, a smaller volume of heat would sweep the heating surface, less water would be evaporated, and the smokebox temperature would prabably be lower.

The outline provided for all observations usual in boiler testing, and, in addition to these, for a determination of the weight of fuel lost in the form of sparks, and for chemical analyses of the fuel used, of the sparks caught and of the smokebox gases.

The first test was run with the locomotive under normal conditions. The whole grate was covered with fuel, the throttle was fully open, the cut-off approximately 6 ins. and the load such as to make the speed 25 miles per hour. These conditions gave a rate of combustion of 61 lbs. of coal per sq. ft. of grate per hour.

In preparation for the second test, one-quarter of the grate was made non-effective, or "deadened" by a covering of fire-brick. The exhaust tip was reduced, so that while the engine was running as before and using approximately the same amount of steam, the same total weight of fuel could be burned on the reduced grate as in the first test had been burned on the whole grate. Trial tests were run until it was known that the changes made would permit the desired conditions to be maintained. The rate of combustion in this test was 84 lbs. per sq. ft. of grate.

In preparation for the third test, the grate surface was reduced to half its original area, and the rate of combustion was increased to 124 lbs. per sq. ft. of grate; and during the fourth test only one-quarter of the original grate was used, the combustion in this case rising to 241 lbs. per sq. ft. of grate.

It should be evident from what precedes, that the prescribed conditions were designed to make each test a duplicate of every other test, excepting in the matter of grate area, this being the one variable for the series.

The coal used in the several tests was of uniform quality, the chemical analyses showing no greater variation than might occur in different samples from a single shipment. The maximum weight of coal fired per hour in any test was 1,087 lbs. and the minimum was 1,038 lbs., a difference of less than 50 lbs. in more than 1,000, while the variation during three of the four tests does not exceed 1.2% of the weight fired. All external conditions affecting the action of the boiler were uniform throughout the series.

The one variable for the series—namely, a different rate of combustion—was secured by keeping constant the weight of coal fired and by varying the area of the grate. There were burned each hour on each square foot of effective grate surface, 61 lbs. during the first test, 84 during the second, 124 during the third, and 241 during the fourth. These values more than cover the entire range of rates usual in locomotives.

Evidence of losses at the grate with increased rates of combustion is to be found in the record of water evaporated per pound of coal, which, for the several tests, is as follows:

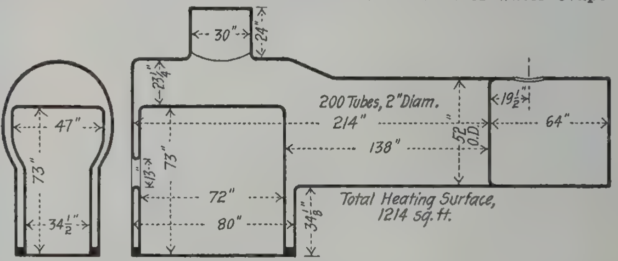

Fig. 3.—Sections of Locomotive "Schenectady" at Purdue University.

Number of test	1	2	3	4
Rate of combustion; lbs. of coal per sq. ft. of grate surface	61	84	124	241
Equivalent evaporation from and at 212° F.; lbs. of water per lb. of coal	8.26	7.87	7.52	6.67
Loss of evaporation in terms of the evaporation for Test No. 1, per cent		4.7	9.0	19.2

In consideration of all the conditions governing the experiments, it would seem fair to assume that the decrease of 19% in the weight of water evaporated, a result which comes from increasing the rate of combustion from 61 to 241, is a loss which occurs wholly at the grate.

A large fraction of this loss is to be accounted for by the escape of sparks, and it is significant that, as the sparks increase in volume, their heating value also increases.

---

*Abstract of a paper presented at the meeting of the New York Railroad Club, Sept. 17, 1896.

**Professor of Mechanical Engineering, Purdue University, Lafayette, Ind.

By reducing the weight of sparks to an equivalent weight of coal, on the basis of their relative heating value, it is possible to make the following comparison:

Number of test	1	2	3	4
Rate of combustion	61	84	124	241
Total lbs. of coal per hour	1,074	1,078	1,086	1,038
Total lbs. of sparks per hour	61.5	95.1	128.6	176.3
Lbs. of coal equivalent to spark losses per hour	46	77	111	161
Value of spark losses in per cent. of coal fired	4.3	7.2	10.2	15.5

According to popular judgment, the loss of heat by sparks has always appeared small; while the data show that, under conditions which are now common, it may represent more than 10% of the fuel value of coal fired. It is evident, however, that these losses will in general depend very much upon the quality of coal, and it should be noted that the Brazil block which was used in the tests under consideration is quite friable.

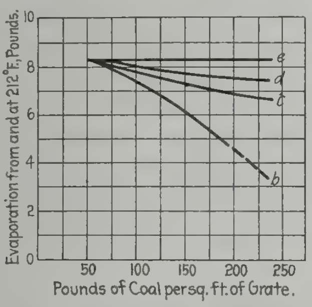

Fig. 2.—Relation Between Rate of Combustion and Losses of Heat by Different Causes in Locomotive Boilers.

Without attempting a full discussion of the analyses of the smokebox gases, attention may be directed to two important facts. These are, first, the large percentage of oxygen shown, indicating a supply of air greatly in excess of that required for combustion; and secondly, the absence of carbon-monoxide (C O) in all excepting the last test.

All air admitted to the furnace in excess of that required for combustion is heated from the temperature of the atmosphere to that of the smokebox, and by this process heat is taken from the furnace. As the data show an increasing amount of air during the third and fourth tests of the series, it would appear that this cause must have operated to reduce the performance of the boiler as the rate of combustion was increased.

The presence of carbon-monoxide (C O) in the smokebox gases is accepted as proof of imperfect combustion. This gas, as already noted, occurs only in Test No. 4. It has long been supposed that its formation is due to thick firing, and its failure to burn after it is formed, to deficient air supply, or to a temperature too low to ignite it. Upon this theory, its presence in Test No. 4, and its absence in the other three, are difficult to explain.

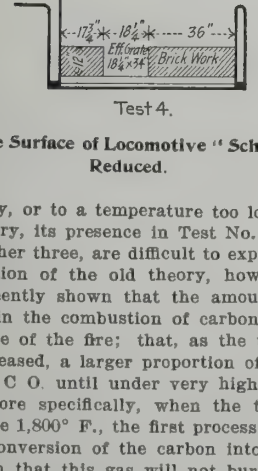

Fig. 4.—Grate Surface of Locomotive "Schenectady" as Reduced.

In contradiction of the old theory, however, Herr R. Ernst* has recently shown that the amount of this gas (C O) formed in the combustion of carbon depends upon the temperature of the fire; that, as the temperature of the fire is increased, a larger proportion of the carbon is converted into C O. until under very high rates of combustion, or, more specifically, when the temperature of the fire is above 1,800° F., the first process of combustion is the entire conversion of the carbon into this gas. He has also shown that this gas will not burn, even in the presence of air, so long as its temperature is above 1,800° F.; it must be cooled before it will burn. But, theory aside, the facts remain that the tests show very small losses by imperfect combustion, even when the rate of combustion is highest.

Conclusions.

The results show that the most efficient furnace action accompanies the lowest rates of combustion; and while the precise relationships established by the experiments may not hold for fuel which is different from that employed, nevertheless they enforce the general conclusion that very high rates of combustion are not desirable, and, consequently, that the grate of a locomotive should be made so large that exceptionally high rates will not be necessary. They emphasize, also, the importance of spark losses, which, during the experiments under discussion, practically equalled in value all other losses occurring at the grate.

Leaving the conditions peculiar to the experiments, and assuming that the results obtained from them may be applied to the locomotive "Schenectady," when working under normal conditions, we find that the losses in evaporative efficiency which occur when the rate of combustion is increased above 50 lbs., may be accounted for approximately as follows: The relation between the rate of combustion and the water evaporated per pound of coal, under normal conditions, is represented by the line a b, Fig. 2. If it could be assumed that the heat developed in the furnace would be absorbed with the same degree of completeness for all rates of combustion, the evaporation would rise to the line a c; if, in addition to this, it could also be assumed that there were no spark losses, the evaporation would rise to the line a d; finally, if, in addition to these, it could be assumed that there were no losses by the excessive admission of air, or by incomplete combustion, then the evaporation would remain constant for all rates of combustion, and would be represented by the line a e.

That is, with the boiler under normal conditions, the area a b c represents the loss occasioned by deficient heating surface, the area a c d that occasioned by spark losses, and the area a d e that occasioned by excessive amounts of air and by imperfect combustion.

Apparatus and Methods.

The apparatus employed constitutes a portion of the permanent equipment of the locomotive laboratory of Purdue University. The locomotive is of the eight-wheeled type, with 17 × 24-in. cylinders, and weighs 85,000 lbs. The boiler, with which the present work especially concerns itself, is shown in outline by Fig. 3.

The deadening, which was employed to cut out portions of the grate, was of brick laid up in fire-clay, the effect being to make the covered portions of the grate as nearly air-tight as possible. The material extended across the breadth of the firebox, the sections of the grate covered being disconnected from the rocking mechanism, so that the remainder could be used with undiminished effect. Its distribution during the several tests is shown by Fig. 4.

Early in the second test, ash piled up on the deadening, as indicated by the line a b, Fig. 4; but as the accumulation did not reach the lower tubes it was not dislodged. During the third test there was less of this deposit, and during the fourth still less, an effect probably due to the presence of a stronger draft.

The thickness of fire for each test was not greater than was necessary to the easy maintenance of the steam pressure. The firing was always at regular intervals, and usually only three shovelfuls were thrown in at one time. In the fourth test the thickness of the fire equaled that of the deadening.

The samples of smokebox gases for analyses were drawn from a point near the center of the smokebox. Ten minutes were occupied in obtaining the sample, a period sufficiently long to cover all conditions of fire.

The smokebox temperatures were obtained by means of a Le Chatelier electric pyrometer.

The weight of sparks or cinders passing the heating surfaces is the sum of those caught in the front end of the locomotive and those passing out at the top of the stack. The sparks which accumulated in the front end were easily collected and weighed. Of those which passed out of the stack, a portion only were collected, the sample being so chosen as to serve as a basis from which the value of the whole could be estimated. The apparatus employed in this latter process is shown by Fig. 5. It consists of an inverted U-tube of galvanized iron, securely fastened to a movable frame, by means of which the tip, which constitutes one extremity of the tube, can be projected across the top of the locomotive smokestack. The outer end of the tube may thus be made completely to intercept a portion of the stream issuing from the stack, and the continuous action of this stream is sufficient to drive the intercepted portion through the tube and out at the other end. The gases passing the tube bear the sparks on their current, and they are collected in a bucket set to entrap them. Reference marks upon the sliding and the fixed frames permit the tubes to be placed in definite locations relative to the center of the stack. This device, when in service, catches everything excepting the lightest soot, which is allowed to escape unaccounted for.

After assuming the cross-section of the stream issuing from the stack to be cut up, by a series of concentric circles, into one circular and several annular areas, as shown by Fig. 6, the small end of the U-tube was placed in the position marked I and held there for thirty minutes, the sparks collected during this interval being credited to this position. The tube was then moved to the position II, where it remained for another period of thirty minutes. In like manner, it was made to occupy, successively, the positions III and IV, and also the positions I_1, II_1, III_1 and IV_1, the weight of sparks caught during each interval being credited to the corresponding position occupied by the small end of the tube. This end of the tube had an area of 1 sq. in., and it was assumed that the average weight of sparks passing the tube while in the positions I and I_1 would be the same as that passing every square inch in the annular space in which these positions are located.

The engines of the locomotive were not involved in the tests, excepting as they served to shake the boiler, to furnish draft and to consume the steam generated. While

Evaporation.—Water evaporated per lb. of dry coal, lbs.	6.94	6.60	6.30	5.58
Equivalent evaporation from and at 212° F.	8.26	7.87	7.52	6.67
Horse-Power.—Boiler, HP.	257.00	248.00	226.00	201.00
Per sq. ft. of grate	15.00	19.00	26.00	47.00
Ratio heat developed in furnace to heat absorbed by water*	.61	.59	.56	.50

*Approximate Efficiency.—The efficiency is approximate only, since the heating value of the coal is only approximately known. Since the same coal was used for all tests there can be no error in using this factor for purposes of comparison within the limits of the present series of tests.

---

*"The Principles of Combustion," a paper by R. Ernst, published as an inaugural dissertation at the University of Giessen, Hamburg, 1892. (See "The Engineer," London, Aug. 4, 1893.)

the speed was varied slightly in different tests as a means by which desired rates of combustion might be the more readily secured, it was approximately 25 miles per hour for all tests. The running for each test, therefore, was equivalent to 150 miles.

As a rule, all important observations were checked by independent means. It is believed that these and other precautions taken were sufficient to insure accuracy in the observations recorded for the several tests.

Aside from their use as a means of checking other readings, the record of the Bristol recording gages was useful, also, in showing with what degree of constancy the desired conditions were maintained. In test No. 4, for which the rate of combustion was maximum, while the firing was difficult, the pressure did not often vary 5 lbs. from 130, which was the pressure desired.

As shown by the data obtained from frequent readings of a manometer attached to the smokebox, the normal draft for this test was equal to 5.6 ins. of water. The chart shows the maximum draft to have been 7 ins., and the minimum to have been about 3 ins. The results of the tests show that this draft of 5.6 ins. resulted in a rate of combustion of 241 lbs. per sq. ft. of grate per hour. It would at first appear impossible that so light a draft could produce so high a rate of combustion. The explanation is to be found in the fact that the effective area of the grate was small, the volume of furnace gases moved was much below normal for such a rate of combustion, and their velocity through the tubes was consequently low. The effect of the draft was, therefore, not greatly diminished by work done in the tubes, but was concentrated upon the fire, with the effect noted.

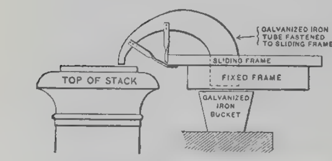

Fig. 5.—Apparatus for Collecting Samples of Sparks.

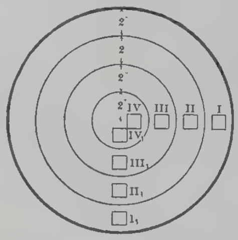

Fig. 6.—Sections of Area of Top of Stack From Which Sparks Were Collected.

These recording gages were not used to supply the data used for the test, but the comparisons just described are sufficient to indicate the great value of self-recording apparatus, as a check against gross errors in readings taken from the more usual and more accurate instruments, and as a means of tracing the relations of cause and effect. It should be noted, also, that it is only since the advent of the laboratory that it has been possible to use such delicate instruments in locomotive work.

LAYING WATER MAINS.*

By J. H. Decker, Deputy Water Purveyor, Brooklyn, N. Y.

One of the most important considerations (in pipe line construction) is the reduction to the minimum of the frictional resistance to flow of water. To this end the writer has all pipe of 12 ins. diameter and over enlarged at the joints, chamfering both at the spigot and hub ends of the pipe. This chamfer is for 12 to 30-in. pipes, 1¼ and ⅛-ins., and for 36 to 48-in., 1½ and 3-16-ins., respectively, the greater figures denoting measurements along the length and the lesser along the thickness of the pipe.

All loose rock and boulders should be removed from the trench; a rock surface should not be permitted to remain within 1 ft. of the pipe, except in cases where the trench is put through solid rock. In such cases the pipe should be raised clear of the rock surface with blocks of good sound timber and imbedded to a depth of at least 1 ft. from its upper surface in sand, loam or clay, which should be thoroughly tamped and rammed in about it. Whenever water should occur in a trench it should be drawn out and kept out until a firm foundation for the pipe shall have been obtained and until the joints have been properly calked. If the bottom should be soft or marshy, and liable to be insecure, it should be made safe and stable with masonry or concrete. In many cases it may be necessary to put in pile foundations for the pipe.

Each pipe, special, or gate of 24 ins. diameter and over should be laid upon two blocks firmly and evenly imbedded in the ground and should be adjusted to line and grade by means of wedges, which should be left in place. The blocks must be sound spruce or other good timber, as the locality may afford, and of a length equal to the diameter of the pipe. For 24 and 30-in. pipe the blocks should be 6 ins. wide and 6 ins. thick; for 36 to 42-in., 8 ins. wide and 6 ins. thick; for 48-in. and upwards, 8 × 8 ins. There should be for each block two wedges made from good sound 4-in. yellow pine or other equally good timber, sawn diagonally from end to end, and of length sufficient to cause the angle of the wedge to conform to the periphery of the pipe.

The spigots of the pipe should be so adjusted in the hub as to give a uniform space for lead all around. If from eccentricity of the hub or spigot, or from other cause, such space cannot be obtained, the defective pipe should be rejected. The width of this lead space should at all points be not less than ¼-in. for all pipes of 20 ins. diameter and under; not less than 5-16-in. for pipes 24 to 36 ins., and not less than ⅜-in. for pipes of 40 ins. and upwards. The depth of the lead in each joint should be, for 20 ins. and lesser diameters, 2 ins.; 24 to 36 ins., 2½ ins.; and for 40 ins. and greater diameters, 3 ins.

The gaskets should be of clean, sound hemp yarn, free from tar, braided or twisted and tightly drawn and should be driven firmly against the bead of the spigot and solidly calked up to the depth to receive the lead.

The lead should be of the best quality of pure soft metal, without admixture of any kind. No joint should be poured until the lead has been heated to a temperature of not less than 720° F. and all scoria has been removed.

Gates of 20 ins. or less diameter may be made with direct spindles and be set vertically, and should be covered with a good large iron gate box. All gates over 20 ins. should preferably be geared and set horizontally, and should also be provided with bypasses of suitable diameter. These should be set in good roomy brick vaults fitted with proper manholes with iron frames and covers.

On all trunk mains blow-offs of suitable size should be placed at all low points. At all high points air-cocks should be put in to free the main from any accumulation of air.

The writer is now in charge of the laying of about nine miles of 48-in. main for the city of Brooklyn. This is the third main of that size in the city, and with two lines of 36-in., comprises the trunk mains of the distribution system. In preparing his specifications he has embodied all of the foregoing points. All of the 30, 36 and 48-in. gates for this line are operated by hydraulic cylinders, which are guaranteed to open or close the gates against a pressure on the main, due to a head of 175 ft., with 25 lbs. pressure. The weight of these 48-in. gates is about twelve tons each; the average weight of the pipe, which is 1 5-16 ins. thick, 8,200 lbs. per length.

POLLUTION OF THE NAUGATUCK RIVER by the city of Waterbury, Conn., may be prevented by a court injunction. The hearing on the petition for the injunction is to be held at New Haven, Oct. 6.

MECHANICAL FILTERS, built by the New York Filter Mfg. Co., have just been put in service at Westerly, R. I. There are three 13-ft. wooden filter tanks with a combined capacity of 1,500,000 gallons per day.

A GREAT INTERCEPTING SEWER is to be put under contract at Cleveland, O., this fall. The sewer will be built along the valley of Walworth Run and will be 14,000 ft. in length. It will be 8 ft. in diameter at the head and 16 ft. 9 ins. diameter at the lower end. It will be of circular section and will be built of brick. The plans for the sewer were prepared by Mr. C. G. Force, M. Am. Soc. C. E. Besides the main sewer a large system of tributaries will be built, aggregating 32 miles in extent.

BIDS FOR GARBAGE COLLECTION AND DISPOSAL for the city of Brooklyn are called for by the Commissioner of City Works and are to be received until Oct. 5. The bidder must undertake the work from Jan. 1 next for a period of five years, and must agree to install some system that has been in successful use in this country for at least three months. The present garbage contractor of Brooklyn receives $129,000 a year.

A WATER POWER AND ELECTRIC PLANT is to be established at Chambly, Que., by the Chambly Water Power Co. There will be a concrete dam 28 ft. high and 1,100 ft. long across the Richelieu River, and the contract for turbines, etc., of 20,000 HP., has been given to the Stilwell-Bierce & Smith-Vaile Co., of Dayton, O. The power house will be at the dam and the power will be transmitted to Montreal, a distance of 15 miles.

THE RENO INCLINED ELEVATOR has been installed experimentally at the old iron pier, Coney Island, at an expense of about $1,000, in order to illustrate the working of the device to officials of the Brooklyn Bridge and the elevated railways. This elevator was described and illustrated in our issue of Aug. 25, 1892.

SMOKE IS NOT A NUISANCE under some circumstances, according to a recent judicial opinion, and the verdict of a jury in Pittsburg, in a suit brought against the Terra Cotta Lumber Co. In his charge to the jury Judge Slagle said that the mills and works along the river and other places, from which smoke and noises issue, were essential to the existence of the community and that every person has a right to carry on a legitimate business, provided it is carried on as such business is usually conducted. Some businesses are a nuisance in themselves, "such as soap boiling establishments, lead works and many others," but these must be located in a spot not in the reach of persons. In a case like the one on trial, his honor said, and when the existence of the so-called nuisance is not necessarily injurious to the health, the surrounding circumstances must be taken into consideration to arrive at a determination, and it must be found that the immediate community is annoyed to convict. The jury accepted the opinion of the judge and returned a verdict of not guilty.

THE CASCADE LOCKS on the Columbia River, Oregon, are practically completed by the U. S. government and the first steamer passed through on Sept. 17. They will be formally opened for traffic on Nov. 15, after being more than 15 years under construction.

A CONNECTICUT WIDE-TIRE LAW went into effect on July 1, 1896, providing that all heavy vehicles made after that date and used upon the highways of that state should have tires from 2½ to 4 ins. wide, according to character. A penalty of $100 was fixed for any violation of this statute. There seems to be considerable opposition to this law and so far it does not seem to be enforced. Individually the wide tire is deemed advantageous; and the fact that the statute requires a departure from old practice appears to be the only reason for noncompliance with its terms.

AN INTERESTING CASE OF RIVER POLLUTION is reported from Indianapolis. The company which supplies that city with water some time ago obtained a perpetual injunction against the American Strawboard Co., prohibiting that concern from discharging into the White River the refuse from its mills at Noblesville. This concern thereupon built a huge reservoir for impounding its refuse by building an embankment across a low place in the river. Into this reservoir 3,000,000 gallons of refuse per day was discharged. The embankment finally broke and the refuse was swept into the stream. The court found the strawboard company guilty of negligence, fined it $250, for contempt, and declared the water company entitled to recover damages, the amount of which should be settled by a jury.

AERATION OF WATER IN A LONG SUPPLY MAIN is being practiced at Norfolk, Va., for the purpose of purifying the water and preventing growth of vegetable organisms.

THE HARRISBURG (PA.) FILTRATION COMMITTEE has reported that mechanical filters are better adapted to conditions there than sand filter beds; but advises postponement of action until the result of the Louisville tests are known and until financial conditions improve.

THE STRENGTH OF A BICYCLE FRAME is shown by the results of competitive tests recently made between steel frames made by E. C. Stearns & Co., of Syracuse, N. Y., and "luminum" frames, made by the St. Louis Refrigerator & Wooden Gutter Co. The steel frame was found superior in every kind of test. The following are the average results of the tests of the steel frames:

	Crippling.	Ultimate.
Static load on crank hanger, lbs....	2,925	4.172
" " on seat post, lbs.	4,275	5,438
" " in line of sprockets, lbs..	.....	2,600
" " on pedal, one side, lbs. ..	845	1,250
Impact on seat post, inch-lbs.......	13,300	15,900
" " crank hanger, inch-lbs...	8,678	9,857
Horizontal impact on front fork....	3,544	4,463

STEAM PUMPS OPERATING WITHOUT OIL in their steam cylinders is a novel practice, adopted, for the first time, we believe, in the pumps furnished by The Geo. F. Blake Mfg. Co., of New York, for the new torpedo boats recently built by the Herreshoffs for the U. S. Navy. The pumps are constructed without any oil holes whatever, so that it is impossible for oil to get into the steam cylinders. They were given an exhaustive test for several days at the works, and they operated with entire satisfaction without using a drop of oil. The main engines of the boats will also be run without oil, but this is not a new idea with vertical engines. If the steam cylinders of both engines and pumps can be run successfully without oil, it will do away with the need for feed-water filters and with the danger of oil injuring the boilers.

A DEVICE FOR LOCATING SUNKEN WRECKS has been invented by a Baltimore man. It consists of a buoy to which is attached a long coil of rope, the whole loosely contained in a metal cage on the deck of the vessel. When the vessel sinks the buoy floats on the surface of the water, one end of the rope remaining fastened to the vessel. The buoy contains a bell which will be rung by the motion of the waves, and also a box in which may be deposited the story of the disaster which led to the sinking of the vessel.

---

*Brief abstract of a paper read before the American Water-Works Association in May, 1896.

A CONTRACT FOR THREE MILES of 42-in. steel force main at Duluth, Minn., has been awarded to Mr. N. F. Hugo for $117,000. The plates will be rolled by the Ironton Structural Steel Co., of Duluth, and the pipe will be shaped and riveted by Mr. Hugo. A contract will soon be let for laying 1,500 ft. of 60-in. steel intake pipe, now on the shore ready to be put in place. The shore end of the intake will be in 20 ft. and the outer end in 60 ft. of water. The pipe will be laid in a trench excavated in solid rock. Mr. W. B. Patton is city engineer and Mr. E. J. Duffies is assistant engineer.

◆

THE DANUBE SHIP CANAL, through the Iron Gates, was formally opened to traffic, on Sept. 27, in the presence of the Emperor of Austria and the Kings of Roumania and Servia. Owing to the obstructions in the Danube, between Alt-Orsova, in Hungary, and Gladova, in Servia, the passage down the river for boats drawing 5 ft. or more of water was impracticable for 117 days out of the 225 days in which navigation is nominally open. And for boats drawing 6 ft. of water the river was never navigable between Bazias and the Iron Gates, a distance of nearly 80 miles. The rock dikes across the river have been now removed and a canal has been cut through the obstructions at the Iron Gates, this canal being about two miles long, 260 ft. wide and 10 ft. deep. The river has now been made navigable, for vessels drawing not more than 10 ft., from Vienna to the Black Sea, at a cost of about $10,000,000.

◆

THE ERIE CANAL TRACTION CO. is reported as sold to an English syndicate for $3,000,000, though the exact terms and proportion of stock transferred are not yet known. The sale was made by the Cataract General Electric Co. and it covers the right to construct an electric towing system along the canal. Meanwhile the right of the Cataract General Electric Co. to erect poles along the canal and the validity of the franchise generally are being questioned by interested parties, on the ground that the franchise for the installation of an electric towing system was obtained through political intrigue and without compensation to the state.

◆

THE LAKE ERIE AND OHIO RIVER SHIP CANAL report, which cost about $35,000, lies in the vaults of the Pittsburg Chamber of Commerce from lack of funds for compilation and publication. It seems that the city of Pittsburg has not yet turned over its appropriation for the canal and appeals to the public have been as yet unavailing.

◆

THE TWELVE NEW LAKE STEAMERS of the Bessemer Steamship Co., controlled by Mr. John D. Rockefeller, which are designed for carrying the iron ore of the Mesabi range from Duluth to Cleveland and other lake ports, are to be given the names of great engineers. The flagship is the "Sir Henry Bessemer," and the others are to be named "Stephenson," "Ericsson," "Corliss," "Krupp," "Fulton," "Watt," "Siemens," "Bell," "Fairbairn," and "Holley." The steamers are each designed to carry 4,000 gross tons on a draft of 14 ft. It is said that these vessels will be able to carry ore from Duluth to Cleveland as low as 50 cts. per ton, which should materially decrease the cost of making pig iron in Pennsylvania and Ohio from Lake Superior ores.

◆

TWO LARGE STEEL STEAMERS, for use in the Lake trade, are now approaching completion. The largest of these, the "George Stephenson," is being built at Bay City. Its dimensions are 428 ft. long over all, 408 ft. between perpendiculars, 48 ft. beam, 28 ft. depth of hold. The triple expansion engine has cylinders 25, 40 and 67 ins. diameter and 44 ins. stroke. There are three Scotch boilers, each 13 ft. 3 ins. diameter and 12 ft. 3 ins. long. The propeller is 13 ft. 6 ins. diameter and 17 ft. 6 ins. pitch. The estimated carrying capacity of the vessel is 4,000 gross tons on 14 ft. 6 ins. draft. On Sept. 23, the "James Watt," was launched at Cleveland, Ohio. This ship is 426 ft. long over all, 48 ft. beam and 29 ft. in minimum depth of hold. She cost $260,000 and is built to carry 4,000 tons of ore on a draft of 14. ft. 6 ins., and 6,000 tons on 18 ft. 6 ins. Both these huge freight carriers are owned by Mr. John D. Rockefeller, and are to be used to carry ore from his extensive mines in the Mesaba Range.

◆

THE SINGULAR STEAMER "HOWARD CASSARD" has been sold at auction in Baltimore for $1,000. The vessel was long and narrow, so narrow as to be very unstable, but the inventor's idea was to drive it so fast (35 to 40 miles per hour) as to give it an artificial stability. The hull is 220 ft. long, 16 ft. extreme beam, and 18 ft. 6 ins. deep, a very heavy and deep keel being used. The engines drive a four-bladed screw 9 ft. 8 ins. diameter.

◆

A FLOATING DOCK is to be built at Havana, Cuba, and proposals for its construction and operation are being received by the firm of R. Z. Jimenez & Co., 44 Broad St., New York city. The dock will be of mild steel and will have a capacity of 12,000 metric tons.

◆

DRY-DOCK NO. 2, AT THE BROOKLYN NAVY YARD, lately damaged by the lifting of the caisson gate during a change in the ballast, has now been emptied and is being cleaned out. The damage is said to be somewhat greater than was at first reported and a second session of the naval court of inquiry is being held. The rubber gasket from the caisson is an exhibit before the court, and it shows the enormous lifting strain put upon it by being torn in shreds in places.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week was caused by the collapse of a bridge under a stock train near Baraboo, Wis., on the Chicago & Northwestern Ry., Sept. 20. The bridge was under repair at the time. The engineman was fatally injured.——A collision between a southbound passenger train and a train of empty flat cars occurred Sept. 20 at the switch for the Breaker Island spur, on the Delaware & Hudson R. R., near Troy, N. Y. Both engines were damaged and the fireman on the passenger engine was badly crushed by the tender, which telescoped the cab.

◆

THE EXPLOSION OF A LOCOMOTIVE BOILER occurred Sept. 23 on the Cleveland, Cincinnati, Chicago & St. Louis Ry. at Pekin, Ill. The engine was a very heavy freight engine, and was standing in the yard at the time. The fireman was fatally injured.

◆

THE CAVING-IN OF A TRENCH on Fifth Ave., near 44th St., New York city, on Sept. 28, caused the death of one man and injuries to two others. The trench was for new water pipes, and is said not to have been sufficiently protected by sheeting, while a platform across the trench carried a steam boiler and derrick in the work.

◆

AN EXPLOSION OF FURNACE GAS occurred at the Duquesne Steel Works, Pittsburg, Pa., Sept. 20, seriously burning and injuring two men.

◆

THE COLLAPSE OF A FLAT BUILDING under construction at 1078 Madison Ave., New York city, on Sept. 26, has revealed a terribly reckless character of construction and disregard of the building laws, while it also appears to show that the Building Department has not a sufficient force of inspectors to properly supervise the building work in progress. The building was 25 × 85 ft. The walls of the first two stories had been erected, three tiers of beams had been laid and the workmen were engaged in building the walls for the third story, when, without the slightest warning, the entire rear of the structure collapsed, and the walls, timbers, scaffolds and men fell to the cellar. One man was killed and eight were injured. An inspection showed extremely faulty work. It is said that the foundations were insufficient and had settled and cracked before the building fell, while the walls were not of proper thickness and the bricks were badly laid in a mortar that did not adhere to them. The lintels were insufficient to properly carry the masonry, and the flues, instead of being lined with tile throughout were lined only at points open to inspection. The combination of bad foundations and superstructure resulted in the sudden collapse without warning. Mr. Constable, Superintendent of the Building Department, has stated that this year the department was allowed only $265,000 to conduct the supervision of over $90,000,000 worth of building investments. It has 4,200 jobs to look after at present, and but 57 inspectors. These men are paid from $1,100 to $1,200 per year, while a foreman on a job gets about $1,500 per year. The inspector of the district in which the fallen building was situated, stated that he had two districts to look after, containing 220 jobs, and, in addition to these, he was obliged to make from 20 to 22 special investigations each day, and report on them. He had been so busy with this special work that he had not been able to visit the Madison Ave. house at all.

◆

AN INCREASE IN ZYMOTIC DISEASES traceable to polluted water supply is again agitating the people of Chicago. Within the last fortnight the chemical analyses of the water from the various supply tunnels has shown it to be in a dangerous condition from sewage pollution, and within the same time the reports of the health officer have shown a rapid and dangerous increase in typhoid fever, so great an increase, indeed, that the health officer seriously considered the closing of the public schools where lake water only is available to the pupils. A committee of the grand jury for Cook Co., Ill., has also recently presented a report to that body which condemns the city water supply as unfit for use. Naturally these conditions have raised considerable discussion in the daily press and under the direction of Mayor Swift the city officials are exerting themselves to find some remedy. At present the most approved plan is to extend all the water supply tunnels to points four miles from the shore, and it is announced that legislation to this end will be urged upon the City Council.

◆

THE U. S. LIFE SAVING SERVICE, in its annual report for 1895, states that there are 251 life saving stations on the Atlantic, Gulf and Pacific coasts and the Great Lakes; 184 of these being on the Atlantic coast line. There is but one river station; at the Falls of the Ohio, at Louisville, Ky. During the year 675 disasters to vessels on these coasts were reported, involving property valued at $10,725,175. Of this property nine-tenths was saved by the life saving stations and salvage and wrecking companies working together. These disasters involved the lives of 5,823 persons, with only 26 lives actually lost. Of the 675 vessels in jeopardy 73 were lost. On the New Jersey coast, with 49 stations, about 1,000 persons were on board ships in danger and only one life was lost; and only $83,535 worth of property was lost out of the $2,000,000 worth in peril. The total net expenditure for the service in 1895 was $1,285,577.

◆

THE ENGLISH TORPEDO BOAT "SPITFIRE," classed as a torpedo boat destroyer, has lately had her full-power speed trial of six runs over the measured mile. She is said to have made an average speed of, 27¾ knots per hour in the six runs; and for the full 3-hour trial the mean speed was 27.46 knots, or about 31½ miles per hour. The contract speed was 27 knots at 4,000 HP.; but she developed 4,527 HP.

◆

OF THE NEW TORPEDO BOATS lately bid for, two of the 30-knot boats have been awarded to the Bath Iron Works, of Maine, and the remaining one goes to the Union Iron Works, of San Francisco. Wolff & Zwicken, of Portland, Oregon, will build two 22½-knot boats; and of the, 20-knot boats, Herreshoff will build three, the Columbian Iron Works, of Baltimore, will build two, and Hillman Brothers, of Philadelphia, will build one. These eleven boats cover the appropriation of $1,300,000 provided for that purpose. The above awards, as made by Commodore Hichborn, of the Construction Bureau, and Commodore Melville, of the Bureau of Steam Engineering, are yet to be approved by the Secretary of the Navy.

◆

THE COAST DEFENSE MONITOR "PURITAN," for the U. S. navy, is completed, and will go into commission about Nov. 1. This is the last of the five modernized touble-turreted ships of the Monitor type to be finished. The "Puritan" has two steel barbette turrets and is 289½ ft. long, 60 ft. beam, 18 ft. mean draft and has a displacement of 6,060 tons. Her engines are twin-screw horizontal compounds of 3,700 I-HP. Her speed is 12.4 knots and she carries 410 tons of coal. Her main battery includes four 12-in. breech-loading rifles and six 4-in. rapid-fire guns; in her secondary battery are six 6-pdr. rapid-fire guns, two 37 mm. Hotchkiss and four Gatling guns. Her side armor is 14, 10 and 6 ins., with 8 ins. on the turrets and 14 ins. on the barbettes; the protective deck is 3 ins. thick. She was built by John Roach, of Chester, Pa., under the act of Congress of Mar. 3, 1885, but was completed at the New York navy yard. Her sister ships, the "Amphitrite," "Miantonomoh," "Monadnock," and "Terror" carry four 10-in. breech-loading rifles; though the "New Monterey," of a similar type, is armed with two 12-in. and two 10-in. breech-loading rifles.

SINKING A LARGE SUPPLY WELL FOR THE WATER-WORKS OF CANTON, MASS.

The accompanying illustration shows the method of sheet-piling and timbering used to sink a large well at Canton, Mass. The finished well is 40 ft. in diameter and 23 ft. deep, the wall being of hard burned Taunton brick laid in cement, and having a thickness of 20 ins. for the first 12 ft., of 16 ins. for 11 ft., or to the surface of the ground, and of 12 ins. for 3 ft. above ground. The wall rests on a granite foundation 3 ft. wide, the depth not being stated.

The site is within about 50 ft. of some springs. Three "soundings" indicated that gravel would be reached at 16 ft. from the surface, and it was intended to carry the well down 18 or 20 ft. deep. The gravel had such an inclination that it was deemed best to go down 20 ft. for the bottom of the well.

The contractor for the well was Mr. Geo. W. Mantle, of Boston, to whom we are indebted for the photograph from which the accompanying view was made. Mr. Robt. Bird was Chairman of the Board of Water Commissioners when the well was sunk, and kindly furnished us with a copy of the annual report of that body, containing a description of the well.

WELL UNDER CONSTRUCTION AT CANTON, MASS.
Mr. Geo. W. Mantle, Boston, Contractor.

In constructing the work Mr. Mantle first removed the muck from a space about 75 ft. square. Within this space he put down heavy timbers, forming two squares, one 50 and the other 30 ft. wide, on each side. Sheet-piling was then driven around the outside of the outer and the inside of the inner timbers, the latter having each of the corners cut off by additional timbering to form an octagon. Bracing was then employed, as shown in the view. The excavated material was lifted out in steel hods by means of a Cram's quick-acting steam derrick. Two centrifugal pumps, with a capacity of 900 gallons a minute, were employed to keep down the water during construction. The earth was removed in horizontal layers 4 ft. deep. After the wall was completed the central core was excavated.

The well is covered with a roof. Water comes in at the bottom and through openings in the brick wall just above the granite foundations.

ELECTRIC MINING IN THE ROCKY MOUNTAIN REGION.*

By Irving Hale, M. Am. Inst. M. E.**

The superiority of electric power for mining purposes was recognized in a general way as soon as the electric motor became a practical success, but it has required time and experience to amplify and fully develop its advantages and to overcome the minor difficulties that arose.

Advantages of Electric Power.

These may be considered under three heads, based on the nature of the generating power:

I. Electricity Generated by Water-Power.
(a) Saving of coal, water for steam (an important item in many places), firemen, handling ashes, boiler repairs.
(b) Electric motors, as now made, require less attendance and repairs than steam or compressed-air engines.
(c) Underground wires are more convenient than pipes
(d) Avoidance of losses by steam condensation underground.
(e) Avoidance of bad effects of steam underground—heating mine, vitiating air, rotting timbers.
(f) Electric motors are more efficient than the small steam and compressed-air engines used on hoists, pumps, diamond-drills, etc.
(g) Rotary motion of electric motor is superior to reciprocating motion of engine for many purposes, especially blowers and diamond-drills.
(h) Electric locomotives are peculiarly adapted to underground haulage where steam is impracticable.

II. Electricity Generated by Steam at Some Distant Point Where Fuel and Water are Cheaper.
(a) Saving of difference in cost of fuel and water between places where power is generated and used.
(b), (c), (d), (e), (f), (g), (h), same as under I.
(i) Superior economy of large compound and, where practicable, condensing engines, over the small, inefficient engines used on most mining machinery, proper allowance being made for losses in transforming and transmitting electric power.

III. Electricity Generated by Steam at Place Where Power is Used.
(a) Disappears.
(b), (c), (d), (e), (f), (g), (h), (i), same as under I. and II.

Counter-Considerations.

Against the advantages enumerated in the preceding section must be charged interest, insurance, taxes and depreciation on the excess of cost of water-power and electric plant over a steam plant for doing the same work; also the greater cost of attendance, if any, due to the location of machinery at two places, although this will in many cases be more than offset by the saving in attendance on motors as compared with steam engines and boilers.

Conditions Affecting the Cost of Plant.

The cost of an electric-transmission plant depends chiefly on three conditions:

First. Nature of water power (assuming such power to be used) and cost of developing it.

Second. Distance of transmission.

Third. Electromotive force or voltage used.

For a given power and electromotive force (which fixes the current) the cost of copper, for a specified percentage of line-loss, varies as the square of the distance.

For a given power and distance the cost of copper, for a specified percentage of line-loss, varies as the square of the distance.

For a given power and distance the cost of copper for a specified percentage of line-loss varies inversely as the square of the voltage.

If the voltage is increased in proportion to the distance, the cost of wire for transmitting a given power with a specified line-loss remains constant.

Table I. shows the cost of copper, at 14 cts. per lb., per K-W. transmitted by the two-wire system for various distances at different voltages, with 10% waste of energy in line.

Considering the fact that the total cost of steam or water power, electric generators, switch-board and motors seldom exceeds $150 per K-W., it is evident that when a distance is reached that makes the cost of wire (and transformers, if used) exceed that amount, or the entire cost of the remainder of the plant, that distance may be considered to be near, if not beyond, the economical limit, unless the conditions are peculiarly favorable for electric power.

With 500 volts this condition is reached inside of three miles; with 1,000 volts, inside of six miles; with 3,000 volts, at about 17 miles, and with 10,000 volts, at about 50 miles (allowing for transformers). It is evident from the foregoing principles and figures that the key to long-distance transmission is high voltage.

Systems.

Direct Current.—Direct-current generators, suitable for power purposes cannot be made to operate successfully at a much higher electromotive force than 1,000 volts, on account of the arcing and short circuiting of the commutator and its connections required to rectify the current. The direct current cannot be transformed to a higher voltage, except in a machine similar in construction to a generator and open to the same objections.

Single-Phase Alternating Current.—The single-phase alternating-current generator can be wound without difficulty for 3,000 to 4,000 volts, and considerably higher if necessary, as the current is taken off from two continuous rings without rectifying it, thus avoiding the difficulties experienced with the commutators of the direct-current machine.

An alternating current of moderate voltage can be transformed into a current of smaller amperage and proportionally higher voltage, for transmission, and can be retransformed at the other end of the line to any voltage desired for lights or power, the amperage varying inversely as the voltage. The energy remains the same, excepting a small loss in the transformation, not exceeding 2% in large transformers. Many plants are in operation at 10,000 to 12,000 volts, and as high as 50,000 volts has been used experimentally with promising results.

The single-phase alternating current is widely used for lighting, but, being a simple alternating wave, is not suitable for power, as no satisfactory single-phase alternating motor of large size has yet been devised that is self-starting under load and capable of speed regulation.

Multiphase Alternating Current.—A multiphase generator has several windings, so placed as to generate several alternating currents differing in phase; that is, passing the zero and maximum points at different instants. Under the influence of these currents (which may be compared roughly to the cranks of a duplex or triplex engine—no dead-center), multiphase synchronous motors are self-starting under light load, while non-synchronous or induction motors will start under full load, and are capable of speed regulation. The latter possess the good qualities of direct-current motors, and the additional advantage of having no commutator and, unless speed regulation is required, neither collecting rings nor brushes, the wires being simply connected to terminals on the field of the machine. On the other hand, the multiphase alternating current, like the single phase, retains the indispensable quality, for long-distance transmission, of being transformable from low to high voltage for transmission, and from high to low for use at its destination.

In the large number of electric-mining plants installed in the Rocky Mountain district during the past eight years, the following systems have been tried:

Direct current, moderate voltage (500 volts or less).
Direct current, high voltage (900).
Direct current, using several generators and motors in series.
Single-phase alternating.
Two-phase alternating.
Three-phase alternating.

Table II. gives a list, which is believed to be complete and correct, of all electric-power plants for mining and ore-reducing purposes in this district, showing in detail the number, kind and capacity of the machines installed and the distance of transmission.

Electric Mining Machinery.

As will be seen from an examination of the appended list of plants, electricity is being applied to the operation of every kind of machinery used in mines.

*Abstract of a paper read at the Colorado meeting of the American Institute of Mining Engineers, Sept., 1896.

**1263 Columbine St., Denver, Colo.

Hoists.—The first application of electric power, and one of the simplest, was to hoisting; the rotary motion of the electric motor being easily adapted to this work. Most of the earlier machines consisted of street-car motors, geared to flat-friction or V-friction hoists. This type is very satisfactory for small or medium-sized machines, as the friction-gear is an assistance to the motor-controller in smooth starting.

For large hoists a positive geared motor is more reliable; but it is desirable to interpose a friction-clutch or equivalent device at some point between armature and drum, as a safeguard in case of excessive strain on the gearing, caused by the inertia of the armature when the drum is stopped by a too sudden application of the brakes. Mr. D. W. Brunton, of Aspen, has designed a slipping-pinion, which is used on the electric hoists in mines under his management, and serves this purpose admirably.

The choice of the best kind of motor depends considerably on the size of the hoist, its location, and the nature of the work. For an unbalanced hoist of moderate size, especially if placed underground and exposed to dirt and water, the iron-clad series-wound street-car type is well adapted, as it is strong, well protected and designed to stand heavy work on intermittent service. In this motor, efficiency, low heating and absolute freedom from sparking are to some extent sacrificed for compactness and lightness. For large hoists, which are generally located in comparatively clean, dry places, and, if over-balanced, work almost continuously, hoisting and lowering, and in which high efficiency is more important than in small hoists, the stationary type of motor is usually preferable.

The speed-controller is one of the most important features of an electric hoist. On most hoists a variable resistance in armature-circuit is employed; and by making this resistance sufficiently high, a perfectly smooth start may be obtained, even with slack rope. The most satisfactory rheostatic controller, especially for heavy work, is one in which the resistance is cut in and out by a cylindrical switch with magnetic blow-out, which avoids the troublesome effect of arcing at contacts, when the current is broken. In some cases it is practicable to use a double-motor equipment, with series-parallel controller, such as is now employed almost exclusively in street-car work.

By overbalancing a hoist, making the counterweight equal to the dead load plus about half the live load, the work in hoisting and lowering can be made approximately equal, and the maximum current and size of motor can be reduced to considerably less than half of what would be required for doing the same work with an unbalanced hoist. This principle is used in the electric hoists at the Free Silver, Alta Argent and Della S. mines at Aspen, and the Silver Lake mines at Silverton, and will doubtless be employed more generally in the future than in the past.

The Alta Argent hoist, in addition to being overbalanced, is arranged in a novel manner. The hoist, with its motor, is placed on a substantial platform above the head of the incline, and is out of the way of the operator, who is located, with the controlling levers, just below the hoist and on the level where the cars are run off. This gives more room for handling the cars as they are raised, and enables the hoist-operator to do this work.

The largest electric hoist in the world is on the Free Silver shaft at Aspen, Colorado. It is an overbalanced double-reel, flat-rope hoist, equipped with a 100-K-W. 4-pole motor, capable of developing 120 HP. continuously and 150 to 175 HP. intermittently. An auxiliary 60-HP. motor, ordinarily doing other work, is arranged so that it can be geared to the hoist counter-shaft and assist the large motor if necessary. Each reel has 1,500 ft. of 4 × ⅜-in. flat rope, weighing 2¾ lbs. per ft. The cage weighs 1,375 lbs, bucket and ore (hung from cage in sinking) about 2,400 lbs., car and ore about 3,500 lbs., and bailer, containing 111 cu. ft. of water, about 9,000 lbs. Two counter-weights are used, the one for cage and bucket weighing 2,450 lbs., and the one for cage and car 2,675 lbs., the two being combined when bailing. Two armature-pinions are provided (the motor sliding on rails), one for ordinary hoisting giving a speed of 600 ft. per minute, and the other for bailing at 1,000 ft. per minute, which, with the maximum load of about 10,000 lbs. (bailing), would require over 300-HP. net, exclusive of friction in gearing and rope, were it not for the overbalanced arrangement. Actual tests have shown that the average current consumed in hoisting with the counterweight is only about one-third of the amount required when the hoist is unbalanced.

Pumps.—The electric pump presents a somewhat more difficult mechanical problem than the hoist, on account of the conversion of rotary into reciprocating motion, and the importance, in most cases, of compactness and protection of the motor against water. That the problem has been satisfactorily solved, however, is proved by the large number of electric pumps of various kinds and sizes in successful operation.

Duplex and triplex pumps, both vertical and horizontal, are suitable for operation by electric motors. For small pumps, where plenty of space is available, a belted motor affords the cheapest arrangement and gives satisfactory results. In the majority of cases a geared pump with motor on the same base is best. Both spur and worm-gears have been used successfully, various devices being employed with the latter to neutralize the thrust. In the Virginius 70-HP. pump, the armature-shaft carries two worms, one right and one left-hand, working into two gears which mesh into each other. In the 15-HP. pump in the same mine, the armature is placed vertically, and its weight approximately offsets the thrust. In most of the electric pumps made during the past few years, spur-gearing has been used, and with good results.

The sinking-pump is the most difficult to design, on account of the small space available for the motor, and the necessity of enclosing it in a practically water-tight case; but numerous successful pumps of this kind have been made and installed. The three-phase induction-motor is especially adapted to this work, and it has no brushes or moving contacts, and the wires can be carried through water-tight bushings in the case to the stationary terminals on the field.

Speed-control is an important question in electric pumping. Where waste of power is unobjectionable, a rheostat in armature-circuit is suitable. If high efficiency is imperative, and the required variation in speed is not great, it may be economically accomplished by varying the field-strength of the motor, either by commutating a sectional field or by the use of a rheostat. When the generator supplies nothing but the pump, an excellent method is to vary the generator-voltage by changing its speed or field-strength, or both. In some cases a water by-pass can be advantageously used. In others it is best to pump at full capacity intermittently. The most suitable method is a matter of judgment in each case.

Blowers.—The running of blowers and exhausters is another simple operation, the motor being either belted, geared or direct-connected to the blower-shaft. Small outfits of this kind, placed at various points throughout the mine, run continuously with very little attention, and afford the most economical and satisfactory ventilation—far superior to the vitiated air that has passed through air compressors and drills.

Percussion-Drills.—To obtain with electricity the rapid reciprocating motion with varying stroke and necessary elasticity required in a percussion-drill, and at the same time get a machine that will stand unlimited abuse, has been the hardest problem in the mining field that the electrician has had to solve.

Two general methods have been followed. One employs the ordinary rotary motor, connected to the drill by a flexible shaft and producing the oscillatory motion by cranks, cams, levers, springs and similar devices. The other uses the solenoid principle, the plunger being moved back and forth within two solenoids, placed end to end, by currents sent through the two alternately, these currents being shifted automatically at the drill or generator—generally and preferably at the latter.

The solenoid type of drill is the only one that has been used commercially and successfully in this country. These drills were tried in several mines in Colorado and elsewhere about four years ago, but were only partially satisfactory. The principal defects were lack of pulling-power, heating of solenoids, unsoldering of connections and breaking of drill-chucks, due to the crystallization of the bronze of which they were at that time made. These defects have been remedied by better electrical and mechanical design of solenoids and connections, and the adoption of an all-steel plunger and chuck. The improved drills have been used successfully for some time in quarrying and tunneling in the East; and a few plants, as shown in the table, have recently been installed in mines in this vicinity, the operation of which will throw much light on the exact value of the drill for mining use.

Diamond Prospecting Drills.—In contrast with the percussion drill, the rotary diamond-drill is more easily and satisfactorily operated by an electric motor than by any other power, not only because the rotary motion of the motor can be applied directly to the drill, while the reciprocating motion of a steam or air-engine must be converted, but also because the former is much steadier than the latter, and causes less wear and breakage of carbons. Moreover, the transmission of power into a mine by electricity is more economical than by steam or air, and the electric drill, with its wires, can be more conveniently

TABLE II.—LIST OF ELECTRIC-POWER PLANTS FOR MINES, MILLS AND SMELTERS IN THE ROCKY MOUNTAIN REGION.

Abbreviations: DC., direct-current; SP., single-phase alternating current; 2P., two-phase alternating current; 3P., three-phase alternating current; Dr., special alternating drill current.

Note.—Percussion drills are classed, for convenience, as motors and nominally rated at 5 HP. each.

moved from place to place than the steam or air-drill and pipes. On account of these advantages the electric diamond-drill has become a favorite wherever current can be conveniently obtained.

Coal Cutters.—Electricity was successfully used for coal-cutting even when the direct-current motor was the only kind available. The application to the chain-cutter of the three-phase, induction motor, without commutator, collector or brushes, and avoiding all possibility of sparking, has produced an almost ideal machine for this work. Another valuable characteristic of the induction-motor for this kind of service is the fact that, when overloaded beyond a certain limit by striking a hard stratum or by sticking of the cutter, it stops, thus relieving both motor and machine from excessive strains. These coal-cutters are being rapidly introduced in the East, but have not yet been used in this part of the country.

Locomotives.—Electric haulage in mines, under ordinary conditions and where distance and tonnage are not too small, is without much question superior to any other system available. It is more flexible than rope-haulage and more economical than mules or compressed air.

Mine-haulage is similar in most respects to street-railway service; but the locomotives must generally be adapted to narrow gage, the motors should be better protected, the speed is slower and the weight on driving-wheels greater.

The series-parallel controller, now so widely used in street-car service, which throws the motors in series for starting and slow speeds, and in parallel for higher speeds, is not so suitable for a mining-locomotive, for the reason that the slipping of one pair of wheels (which is more liable to occur than on a street-car, the load being behind the locomotive and the rails being more slippery) increases the speed of the motor on that axle, raises the counter-electromotive force and cuts down the current through both motors, if in series, thus reducing the power of both. For this reason some form of rheostat-controller is generally used. The essential requirements in a mining-locomotive are compactness, strength, simplicity, convenience of handling and especially durability and freedom from repairs.

Placer-Mining Machines.—Electric power has been very satisfactorily applied to the operation of placer-mining machines, several motors being employed to run the different parts of the dredge and gravel-treating apparatus. One motor generally raises and lowers the dipper; one forces it into the bank: another works the turn-table for depositing the gravel in the hopper; and a fourth operates the cylinder, tailings-carrier, amalgamator, etc. All of these motors are supplied by a generator located at any convenient point. The peculiar adaptability of electric motors to such work is evident; in fact it would be difficult to operate such a machine in any other way.

The Bennett Amalgamator Manufacturing Co. is operating a plant of this kind for the South Park Mining Co. at Green River, Utah, and the Gold Dredging Co. has a similar installation at Bannock, Montana.

Electro-Metallurgy.

Copper-Refining.—The principal application of electricity to metallurgical operations in this part of the country is copper-refining, which is carried on extensively at Anaconda and Great Falls, Montana. The plant at Anaconda consists of eight electrolytic generators, aggregating 1,870 K-W., and its capacity is 125 tons of refined copper per day, the average output being about 100 tons per day. They also have a 100-K-W., 110-volt power generator, supplying two 25 HP. locomotives and three traveling cranes, for handling and transporting materials and product.

The commercial success of this process is too well established to require discussion. Its economy is principally a question of the cost of power and the scale on which operations can be conducted.

Gold and Silver Extraction.—Electricity has been applied as an auxiliary in various processes for the treatment of gold and silver ores by cyanide, chlorination and amalgamation. While some of these processes are based solely on the faith of the inventor that a current of electricity sent through his mixture will in some mysterious way produce results that he cannot otherwise obtain, others undoubtedly possess merit, as they are founded on well-established laws of electro-chemical action. These processes are usually conducted with considerable secrecy, and it is impossible to give any reliable data as to the actual results accomplished or the economy of the operations. There is reason to believe, however, that, with the proper combination of chemical, metallurgical and electrical knowledge brought to bear upon this subject, good results may be expected.

Future Development.

During the past eight years and principally in the last four years, 52 distinct companies in the Rocky Mountain district alone have installed electric-power machinery for mining and ore-reducing purposes, comprising 62 generators, aggregating 7,988 K-W., and 135 motors, aggregating 4,816 HP., operating every variety of mining and milling machinery.

Electric apparatus, formerly regarded as delicate and peculiarly subject to break-downs, has been brought to such a degree of perfection that depreciation and repairs may be considered as less on this than on almost any other kind of machinery.

The multiphase high-voltage system has brought nearly every mining district within economical reach of water-power. The induction-motor, without commutator, collector or brushes, is the acme of simplicity and durability. Electro-metallurgical operations are increasing and give promise of success. Under these conditions it may be safely predicted that during the next five years much greater progress will be made, and the application of electricity will become one of the most attractive and important features of mining economy.

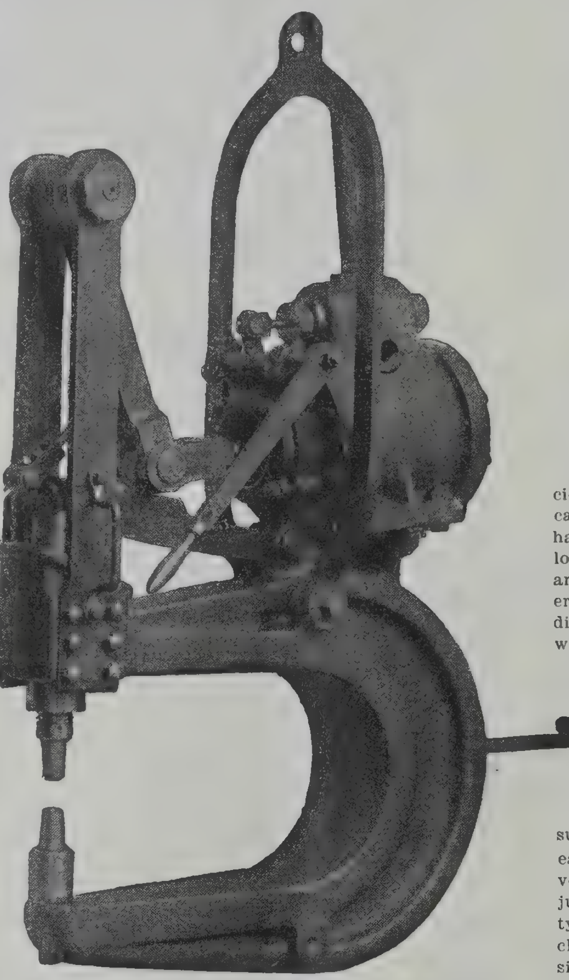
SOME NEW DESIGNS IN POWER RIVETING MACHINERY.

The half-tone cut herewith shows a new form of bridge riveter recently placed on the market by Mr. Chester B. Albree, of Allegheny, Pa. The peculiar feature of this riveter is the means by which the power is transmitted from the air cylinder to the ram. On top of the ram is a roller, on which rests the inclined arm or lever shown in the cut, which is pressed down by the roller at the end of the link to which is connected the pitman or connecting rod, driven by the trunk piston. A toggle joint motion is thus secured, which gives the greatest pressure at the extreme end of the stroke. The yoke of the riveter is of cast steel, of 60,000 lbs. tensile strength. The working parts are of hardened steel. The cylinder is provided with an automatic cushioning device and the valve is perfectly balanced. The machine will balance either horizontally or vertically by the trunnions. The yokes are made of different depths to suit different classes of work, 26-in., 36-in., 60-in. and 70-in. The cylinders are made either 10 ins. or 14 ins. diameter, as ordered. Mr. Albree has also patented an ingenious column riveter for work in contracted spaces where the ordinary power riveter cannot be used or is used only with difficulty. The accompanying cut shows its mechanism.



A NEW PORTABLE RIVETER FOR BRIDGE AND STRUCTURAL WORK.

Designed and Built by Chester B. Albree, Allegheny, Pa.

Either of the above machines are built to operate with compressed air; but can be built for steam or hydraulic pressure where desired. Stationary riveters for heavy work in boiler and tank shops are also built with operating mechanism, similar to that shown on the other machines. The durability of these machines has been tested by their use for some nine months in the structural iron works of Mr. Albree, where it has given the best of satisfaction.

STEAM BOILER PRACTICE IN EUROPE.

Circular No. 5 of the Steam Users' Association, Edward Atkinson, president, contains the report of Mr. R. S. Hale of his visit to Europe to study European boiler practice. The following table, prepared by Mr. Hiller, of the National Boiler Insurance Co. of Manchester, is given in the report:

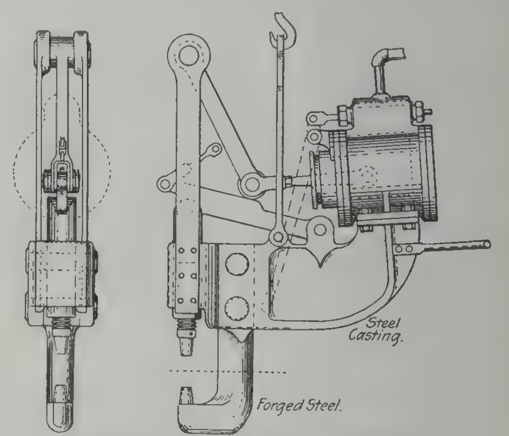
Per Cent. of Boilers of Various Types Used in Europe.

	United Kingdom.	France.	Germany.	Switzerland.	Austria.
Year	1895.	-1893-4.-			
Lancashire & similar types.	38.0	4.7	35.7	19.6	*
Cornish and similar types.	23.7	8.2	15.3	40.8	*
Extern'ly fired cylindrical[1]	6.8	57.3	14.8	15.5	41.0
" " multitubul'r	..	13.4	5.2	3.5	7.5
Locomotive	11.0	5.1	17.3	5.7	10.5
Small verticals	16.6	3.6	5.0	13.5	6.1
Water tubes	1.8	5.7	4.6	1.4	3.8
Other types	2.1	2.0	2.1	..	1.4
Total	100.0	100.0	100.0	100.0	100.0

*Lancashire, Cornish and similar types, 29.7. [1]Including elephant.

From Mr. Hale's comments on the several styles of boiler used we extract the following:

The standard type of boiler, with the exception of France and the Province of Elsass in Germany, was decidedly the internally fired flue boiler known as the Lancashire when it has two flues, and the Cornish when it has one. The Lancashire boiler is generally about 30 ft. long by 7 ft. 6 ins. in diameter. The two internal flues are about 3 ft. diameter, and the grates in them are generally 6 ft. long. Galloway, or cross tubes, about 6 ins. diameter are often placed in the tubes back of the bridge wall, five to each flue, but this is advised against by some of the best authorities. The gases after leaving the furnace tubes pass underneath the boiler to the front, then back along the sides to the underground flue. Such a boiler would have 36 sq. ft. of grate surface and about 1,000 sq. ft. of heating surface, giving a surface ratio of 28. When built for 160 lbs. steam pressure, it costs about $2,500 in England, and will deliver easily 6,000 lbs. steam per hour. At this rate it is not very economical, but if used at a lower rate or in conjunction with an economizer it is as economical as any type of boiler. It is a boiler that is very easy to keep clean since every portion of the surface inside and outside is of easy access.



Portable Riveter for Work on Columns.

The Cornish boiler is exactly like the Lancashire, except that it has only one furnace tube. This single tube is in England placed in the center, in Germany it is placed to one side with the idea of improving the circulation. It is nowadays rarely built except for small plants, so that the average Cornish boiler is probably considered older than the average Lancashire.

In France and in Elsass, Germany, the type of boiler known as the "elephant" is the standard. This is classed under the head of externally fired cylindrical in Mr. Hiller's table. It is not as regular in size or proportion as the Lancashire. The upper shell is generally from 20 to 30 ft. long and some 5 ft. in diameter. The two lower shells called "bouilleurs" are about 2 ft. diameter. They have one and sometimes two connections to the main shell. This boiler has the advantage of allowing a very large grate surface, an important consideration with the poor coals in use on the Continent.

In boiler construction I judged the English workmanship to be fully equal to our best. In England no punching is allowed; the plates are always planed on the edges and then drilled in place. Steel is being used almost exclusively in England; iron is still preferred in some places on the Continent.

The internal flues in the Lancashire boilers are generally welded along the longitudinal seam, and the cross or Galloway tubes are frequently welded in. I did not hear of any cases of welding the boiler-shell itself. The flues are occasionally made corrugated in various ways as the Fox, Purves, and other patents. My impression was that these were considered better, but that most frequently the improvement did not warrant the expense. The steam pressures, of course, varied from plant to plant. I should judge that if 140 to 150 lbs. was considered a standard for a new mill in America, the corresponding practice would be 200 lbs. in England, 180 in Elsass, and 140 to 150 in Belgium and Germany. In all countries I found occasionally higher pressures than the above, and, of course, the immense majority were lower.

Economizers.

The use of economizers is more general in Europe than in America, and the type known as the "Green," now made by several good firms, is the standard. Occasionally on the Continent one of the bouilleurs of the elephant boiler was used as an economizer. The most general practice was to put one economizer for each battery of boilers, making the economizer heating surface and the boiler heating surface the same. In Belgium, however, they were recommending one small economizer to each boiler. Scrapers are used to keep the fire surfaces clear of soot. The water surfaces are subject to scaling if the water be bad, and it is chiefly in the bad water districts that economizers are not used, though they are not much if any, worse in this respect than water tube boilers. But when the economizers are taken out the heating surface of the boilers must be more than doubled to get the same economy.

Heat Storage.

An advantage claimed for the Lancashire boilers and for the economizers was that the large amount of hot water in them afforded a reserve of heat for a sudden call. An interesting application of this principle were the feed torage and the steam storage systems of D. Halpin, Esq., London. The first is applicable to all plants and consists in providing tanks in which the feed is heated to the steam temperature by steam from the boiler during light demand, so that during the heavy demand the feed water is supplied hot (360° F.) instead of 100° or 200°. The steam storage consists in having very high pressure boilers, which pressure is reduced at the engine. Water is heated to boiler pressure during light load and stored in tanks, and during the heavy load expands into steam and relieves the demand of the engines on the boilers proper. The steam storage system did not impress the writer favorably. If you are going to go to the expense of high pressure boilers anyway, then it seems to him that you will be as apt to save coal by using high pressure steam at your engines as by reducing the pressure in order to equalize the load on the boilers. But the feed storage system, particularly where economizers are not used, seems a very practicable method of reducing the net first cost by a few per cent. (the boiler plant saved would cost more than the feed storage), and at the same time probably increasing the economy. Both the feed and steam storage systems are especially available with bad water.

Superheaters.

The use of superheated steam is very much in the air all over Europe, and in Elsass (Alsace) it is fairly general, about 500 superheaters being in use. There has never been any doubt that it saved from 10 to 20% of coal, but the difficulty has been in the lubrication of the engine cylinder and the keeping the large number of superheater joints tight. The Schwoerer superheater, which is much used in Elsass, consists of a small number of very heavy ribbed cast-iron pipes placed in a very hot portion of the flue, as, for instance, between the tubes and the drum of a Babcock & Wilcox boiler. The cast iron is made thick enough so that it may become red-hot without injury, and by being in the hot portion of the flue only a small superheater is required. The trouble with lubrication is overcome by using a high grade mineral oil. In England and on the Continent, several forms of superheaters using thin steel pipes were under test. I did not hear of their sale in any number as yet. The superheaters are also placed above a separately fired furnace in some plants.

Grates.

The grates in ordinary use did not noticeably differ from those in use in America. In Germany some of the under-fired boilers were provided with grates that inclined downwards to the rear as much as a foot or a foot and a half, which was thought to be easier for the firemen and to give better combustion. The ash-pits of these boilers were unusually deep. The coal is frequently very soft and bituminous, but in their internally fired boilers they had no trouble from having the furnace top only 18 ins. or less from the grates, in fact the Lancashire boiler enjoyed a better reputation for smokelessness than many others.

Mechanical Stokers.

In England several forms of mechanical stokers were in use, perhaps over one-quarter of the boilers being equipped. They may be divided into two general classes, the coking and the sprinkling stokers. The coking stokers feed the coal at the front where it cokes and is then carried to the rear by the reciprocating motion of the grate bars. The Vicars stoker is the best known of the class. It is represented in this country by the Roney, Wilkinson, Murphy, Brightman and other types; the chief difference being that on account of the internally fired boilers the Vicars grate bars are level The sprinkling stokers throw the coal over the grates by means of revolving or oscillating shovels; but they generally use as well a reciprocating motion of the grate bars to carry the ashes to the back end. The Bennis stoker is perhaps the most widely used of this class, but there are several good firms who make stokers of each class.

Opinion is, of course, widely divided on the merits of mechanical stokers. What seemed to the writer to be the general drift of opinion of those best fitted to judge, was as follows: No stoker absolutely prevented smoke, but both types very largely diminished it. In this respect the coking stoker had a decided advantage over the sprinkling. Neither stoker kept up the steam pressure on a sudden call as well as hand firing; in this respect the sprinkling stoker was considered to act more quickly than the coking.

The sprinkling stoker was being sold at about three-quarters the price of the coking. The cost of the Vicars stoker was about $500 for two stokers, each 2 ft. 9 ins. or 3 ft. wide and 4 or 5 ft. long.

The opinion as to whether the stokers saved coal was evenly divided. The most general reasons for their adoption were the diminution of smoke, the smoke laws being very strict in England, and the use of a cheaper fuel. The use of a cheaper fuel undoubtedly saved money, but when compared on the same grade of fuel the best opinion, so far as the writer could judge, was that they saved some coal, but not enough to show a net saving after paying the interest and repairs. The saving in labor was not generally considered and did not amount to very much in small plants, or in plants where no coal handling devices were adopted. The use of stokers and coal handling appliances together was thought to save about one-third of the boiler room labor in large plants.

Dust Firing.

In Germany grinding the coal to a powder and blowing this dust coal mixed with air into a hot combustion chamber was a method that was being experimented on in several plants and was meeting with considerable favor. The "Wegener" process is used in England; the "Camp," the "Schwartzkopf," and others in Germany. Fig. 10 shows one of these arrangements. The fine dust (almost as fine as flour) is, however, not only a very dirty stuff to handle but is also exceedingly liable to spontaneous combustion, and the problem of grinding and storing it had not yet been commercially solved so far as the observation of the writer went.

Boiler Fittings.

In boiler fittings several differences were noted. All fittings were noticeably heavier and stronger than with us. The use of spring-loaded safety valves is looked on as yet with a great deal of distrust, and those in most common use are the lever valve and also the dead-weight valve.

The use of try-cocks has been entirely given up in every plant that I visited and two gage-glasses are used instead, having been found not only neater but safer. On the Continent one glass and a mechanical lever indicator were sometimes used.

The dampers on the smoke flues are almost always of the sliding and not of the butterfly type. This may be because the flues are almost always underground. The dampers are always regulated by hand, damper regulators being practically unknown. Forced, induced, steam-jet, and other artificial drafts are no more and no less in use than with us; that is they are not infrequent in special cases where the ordinary draft is insufficient, but they are in no sense general.

The use of guards on the water-gages is very common to prevent pieces of broken glass from injuring the fireman. This is peculiarly necessary since in most of the foreign boilers the water glasses are on a level with the fireman's face.

Pipe Covering.

The average quality of the boiler and pipe coverings did not seem to the writer as good as those in general use in this country. Occasionally he saw wood and even rope covering on high pressure piping, some of which was already distinctly charred. Some plants, of course, had very good coverings, and there was a custom of covering the top of the boilers very thickly with some cheap covering with the result that nine times out of ten the space over the boilers was noticeably cooler than it is in America.

Chimneys.

In regard to chimneys the variety of sizes and of theories is just as great as it is here. The few of which the writer obtained both the dimensions and the amount of coal they were intended to burn were larger than those given in the tables in American books of reference for the same capacity. This may be because in England they lay a good deal of stress on a good draft as an aid in smoke prevention, and the English laws are very strict as to smoke. Brick is almost universal, iron stacks being used only in very exceptional cases.

Boiler Operation.

The admission of air above the fire either at the door or at the bridge was used occasionally. The opinion was very general that this diminished smoke. As to economy of coal, authorities were divided, but the general drift was, that this admission of air resulted in a slight loss.

Boiler surfaces seem to be kept cleaner than is the general practice here. In some places they run the boilers until the specific gravity of the water is 1.005, then they blow out and clean the boiler. In England they use soda, lime and potash in the boilers, according to the impurities, and on the Continent they are also beginning to know about the advantages of kerosene. Purifying plants to take the impurities out before the water enters the boiler are not infrequent but are hardly considered a complete commercial success as yet. A little water is generally blown out once or twice a day just as with us, and in mills the fires are banked at night. In electric stations the custom was very general to let the fires go out when they were not needed. Several plants gave us the result of experiments on the cost of banking fires. Reducing these to 24-hour days and to equal grate areas they run about 40 lbs. per 24 hours per square foot of grate.

The opinion as to the practice of letting the steam pressure off the pipes when the load was off was divided. On the whole it was in favor of the practice, although some plants said they had tried it and had found the cost of repairs to more than balance the saving in coal.

Boiler Testing.

Boiler testing is in some respects more advanced than it is with us, chiefly in that they attempt to tell where all the heat supplied goes to and thus to determine the reasons of good or bad performances.

The bomb calorimeter, in one or the other of its various forms, Mahler, Donkin, etc., is considered the only accurate means of determining the heat value of a coal, though the method of analyzing coal and using one of the numerous modifications of Dulong's formula is quite often employed. The Thompson and other calorimeters of that type are not considered in the least available for practical work. It was the custom to correct the results of the calorimeter for the latent heat of the H_2O formed from the hydrogen in the coal, or, if using the formula, to assume that the hydrogen was burned to steam and not to water. Coal tests are, of course, compared on the evaporation per pound of coal, boiler tests were generally compared on the evaporation per pound of coal "pure and dry," dry referring, of course, to the moisture correction, pure to a correction of the earthy matter contained in the coal, but not allowing any correction for the unburned coal in the ashes. Occasionally, however, pure and dry meant exactly the same as our "combustible." In determining moisture in steam they are as far behind us in their general practice, with the exception of a few of their best engineers, as they are ahead of us in the analysis of the gases. Fortunately at the high steam pressure now in vogue the priming is generally a negligible quantity so that their results have not been affected.

Boiler Economy.

In boiler economy I could not see that they were either ahead or behind us; they get from 60% to 80% of the heat in the coal, according to the air supply and evaporation per square foot of heating surface. None of their engineers had ever found any combustible gases in the chimney, except occasionally a little carbonic oxide. Most of their tests, however, left some zero to 15% of the heat unaccounted for, which may be radiation or error. Some said one, some said the other. No one had experimented as to why it is harder to supply the right amount of air to one kind of coal than to another, though they had all gone as far as to realize the immense importance of the air supply, as compared with any other factor in boiler economy, and also to realize and to experiment on the amount of air that leaks through the settings of some types of boilers to the injury of economy. Frequently more air has been found to leak through the settings than came through the fire. In some plants on the Continent they were painting the brick settings with a heavy tar paint to make them air tight, and occasionally even enclosing them in sheet-iron casings.

THE REVOLVING TOWER, proposed by M. Devic as the feature of the Paris Exposition of 1900, will be only about half as high as the Eiffel tower, or about 500 ft. But it is proposed to make this tower revolve at the rate of about 2½ miles per hour, for any point on its outer wall. The revolving part would be about 80 ft. in diameter and would be fitted up with restaurants, shops, etc., with a public ball-room at the top.

AN EXPERIMENT IN DREDGING WITH DYNAMITE.

Dredging by dynamite has been carried on at the outer bar at Brunswick, Ga., for several years, by Mr. C. P. Goodyear, a lawyer of Brunswick. He began work in the summer of 1891, and expended about $8,000, with, it is claimed, beneficial results. In 1892 he secured an appropriation in the River and Harbor bill providing for compensation in case he secured a certain depth by Jan. 1, 1893. Three surveys were made by the Government engineers, none of which showed the increased depth of water which the act specified. In the River and Harbor act of 1893 the time for securing the increased depths was extended to Nov. 1, 1893, and by the act of next year $30,000 was awarded him for the work done, as shown by the testimony of the masters of vessels passing over the bar, although the surveys of the corps of engineers still showed that the contract depths had not been secured. The same act also appropriated $30,000 additional to be paid Mr. Goodyear if he should secure a minimum depth of 23 ft. in a channel 100 ft. wide across the bar by Nov. 1, 1895. A board consisting of W. W. Duffield, Superintendent of the Coast and Geodetic Survey; Major W. S. Stanton and Capt. F. V. Abbott, Corps of Engineers, U. S. A., was constituted to make surveys to determine whether this depth was obtained. Three surveys were made by this board in 1895, none of which showed that the increased depth had been secured.

Mr. Goodyear again went to Congress, therefore, and by the last River and Harbor bill he is to receive $70,000 when he obtains a channel 100 ft. wide and 24 ft. in depth across the bar; $30,000 additional when he secures a channel 200 ft. in width, with a least minimum depth of 23 ft., and $40,000 additional when a 200 ft. channel with a least depth of 24 ft. is secured. The surveys to determine this increased depth are to be made by an officer of the Coast and Geodetic Survey to be detailed by the Secretary of War. The work must all be done by June, 1899.

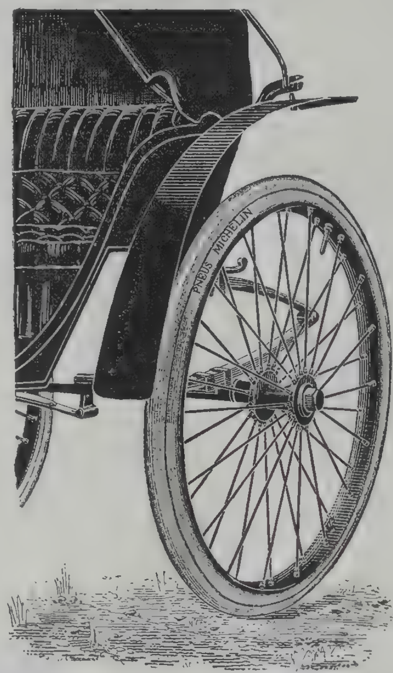
As we understand the matter, Congress, in this latest act, appears to have acted with considerable shrewdness. It refused to give the contractor anything for the 23 ft. channel 100 ft. wide, which was originally contracted for, as the soundings made by the board and by the engineer employed by Mr. Goodyear showed that the depth of the channel was already so close to 23 ft. that this depth might easily be brought about by the natural scour on the bar regardless of any work done, and whether it was secured or not was a matter on which engineers might easily disagree. To secure a depth of 24 ft., however, it seems probable that some real excavation will have to be done by the contractor; and if this depth is actually secured by his efforts, he will doubtless be entitled to compensation.

Respecting the actual merits of Mr. Goodyear's method of deepening channels by dynamite explosions, we are able to find nothing conclusive in its favor. He informs us in a personal letter that he has exploded over 200,000 lbs. of high-grade dynamite upon the bar, in charges from 25 lbs. to 200 lbs. The Board of Engineers in its report dated Jan. 11, 1896, stated that the best practicable channel 100 ft. wide across the bar was obstructed by about 9,000 cu. yds. less material in December, 1895, than in March, 1894, and about 21,000 cu. yds. had also been displaced from areas about 200 ft. wide at the side of this channel; but it says that there is no possible means of ascertaining how much of this was due to natural agencies and how much to Mr. Goodyear's dynamite explosions. On the other hand Mr. H. C. Ripley, an engineer employed by Mr. Goodyear, claims that the latter's operations had resulted in the removal of 785,000 cu. yds. of material in April last.

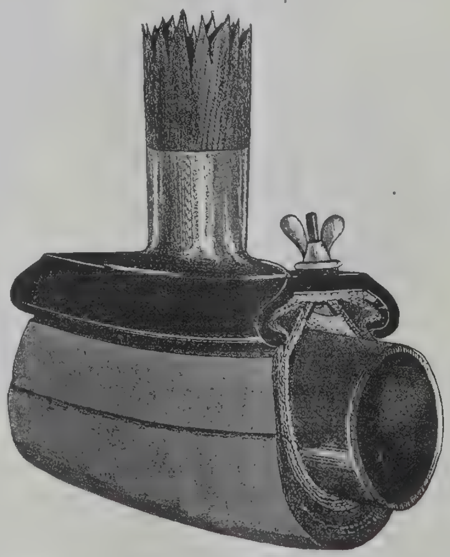
In view of the fact that prior to the wreck of a vessel upon the bar in 1879, there was an excellent channel across it nearly 23 ft. in depth and 900 ft. in width, it seems exceedingly probable that natural agencies are gradually restoring this former condition and that this has more to do with the improvement of the depth across the bar than Mr. Goodyear's dynamite explosions. He informs us that he has expended $133,500 upon this work to date. It appears to us that if he had expended this amount in work with modern dredging machinery, he would have removed a greater amount of material from the bar than even his own engineer claims and would have secured far more beneficial results.

PNEUMATIC VS. IRON TIRES FOR VEHICLES.

In "Le Genie Civil," for Aug. 15, 1896, Mr. Gerard Lavergne devotes considerable space to the application of pneumatic tires to the wheels of vehicles, a practice now quite common with the cabs of Paris. He says that an English engineer, Mr. R. W. Thomson, applied pneumatic tires to the wheels of carriages in 1846, and his device is fully described in "The Mechanics' Magazine" for August, 1846, and April and May, 1847. He at first employed an air chamber of rubber and an exterior envelope of leather; but he later used an air chamber made of canvas and rubber, reinforced by rubber on the rolling side, and very similar to the rubber tire of the present day. On March 17, 1847, Thomson made some experiments upon relative traction efforts, in Regent's Park, and reported as follows:



Pneumatic Tire for Paris Cabs; Bicycle Wheel.



Pneumatic Tire for Paris Cabs; Wooden Spoke Wheel.

	Ordinary wheels, lbs.	Pneumatic tires, lbs.
Over a good surface	45	28
Road covered with newly broken stone	120	38½

According to these figures the economy in traction, due to the pneumatic tire, was about 38% on a good road and 68% over freshly broken stone. It should be said, however, that his dynamometer was crude and the results were merely approximate, useful only for their relative values.

As giving more reliable data, the writer makes an abstract from a paper recently presented to the Society of Civil Engineers by Mr. Michelin, recording some more carefully made experiments of this character. Mr. Michelin used for his registering apparatus a dynametric spring, formed by two articulated plates at one end of the apparatus; one fixed to the vehicle and the other to the whiffletree. With this was used an automatic registering device of somewhat complicated and delicate design.

The first experiments were made with iron and pneumatic tires of the following diameters and weights:

Kind.	Diameter of wheels, Front, ft.	Diameter of wheels, Back, ft.	Weight of wheels, Front, lbs.	Weight of wheels, Back, lbs.	Weight of Empty vehicle, lbs.
Iron tires	3.02	3.67	127.6	158.4	1,269.4
Pneumatic tires	2.95	3.93	85.8	123.2	1,192.4

To the weight of the empty vehicle the weight of the driver must be added; and to make this feature comparable the same driver was used in both cases. These experiments were made over various soils, over different lengths of road, with varying loads and at different speeds. The results of the trials made in January, August and September of 1895 and January and February of 1896 are summed up in the following table:

	Tires, Iron, lbs.	Tires, Pneumatic, lbs.
Experiments in Snow.		
Carriage at a walk, empty	34.89	25.23
Carriage at a walk, load of 330 lbs.	39.22	27.96
Carriage at a trot, load of 330 lbs.	65.12	33.59
Carriage at a trot, load of 660 lbs.	68.57	39.51
Experiments in Mud.		
Carriage at a walk, empty	35.20	23.10
Carriage at a walk, load of 330 lbs.	38.06	27.34
Carriage at a trot, load of 330 lbs.	43.01	28.53
Carriage at a trot, load of 660 lbs.	50.73	31.15
Mean of Trials upon Macadam; dry, new, dusty and well-paved, with grades varying from 1.2 to 5.8%		
Carriage at a walk, empty	38.32	30.91
Carriage at a trot, empty	44.90	35.09
Carriage at a walk, load of 660 lbs.	45.65	35.51
Carriage at a trot, load of 660 lbs.	65.34	36.08

These figures show that under all the conditions given the use of the pneumatic tire diminishes the tractive effort; and this economy is greater upon a bad than upon a good road, as was to be expected, and it also increases with the speed and the load.

Some experiments were made to compare the relative effect of iron tires and pneumatic tires with varying air-pressure and with plain rubber. The results were as follows:

At a trot, load 660 lbs.......44.22 44.75 43.91 56.52

Vehicle.	Iron tire.	Pneumatic Air Pressure. 6.6lbs.	Pneumatic Air Pressure. 9.9lbs.	Plain rubber.
At a walk, empty	33.64	36.03	34.34	37.62
At a trot, empty	46.64	33.99	41.69	44.15
At a walk, load 660 lbs.	44.22	44.75	43.91	56.52
At a trot, load 660 lbs.	64.20	45.14	50.64	63.96
Average	47.17	39.97	42.65	50.31

From this table it would seem that the full rubber tire, while better than iron at a trot, is not so good at a walk. But Mr. Michelin adds that if the surface is muddy, or covered with snow, so as to remove all elements of elasticity, the full rubber tire gives better results than an iron tire. But the full rubber is always inferior in this respect to the pneumatic tire; and for the latter it would appear that the pressure of inflation should not exceed 6.6 lbs. The general mean of the experiments of Mr. Michelin in traction would give the following relative values:

Pneumatic tires	100.0
Full rubber tires	129.8
Iron tires	132.7

The author of the paper concludes with an illustrated description of some of the pneumatic tires used on vehicles in Paris, now generally fitted with metal rods, or spokes, though they can also be applied to wooden wheels. In the latter case the rim of the pneumatic is applied upon the wooden rim holding the spokes; but a better method is to fit upon the ends of the spokes a metal socket, which is riveted directly to the metal rim of the pneumatic.

The metal wheels are of the bicycle type, as shown in the cut, and need little description.

TRESTLE FOR CARRYING A FLUME AT SALTVILLE, VA.

By Emile Low, M. Am. Soc. C. E.

Occasion having arisen to convey away the liquid lime refuse of the Mathieson Alkali Works, with which the author has been connected as engineer, a plan was formulated, of which a flume trestle formed an integral part. Trestles for supporting flumes used in conveying water for irrigation purposes are common enough in the western states and territories, but in looking over the literature on hand on this subject, none was found which might serve as a precedent, and the author was compelled to evolve such a structure as would suit the exigency of the case in hand. As what might be termed in this particular, the rolling load, was comparatively a very light one, the main essential was to design a structure as light as possible, and at the same time possessing the requisite stiffness for stability, etc.

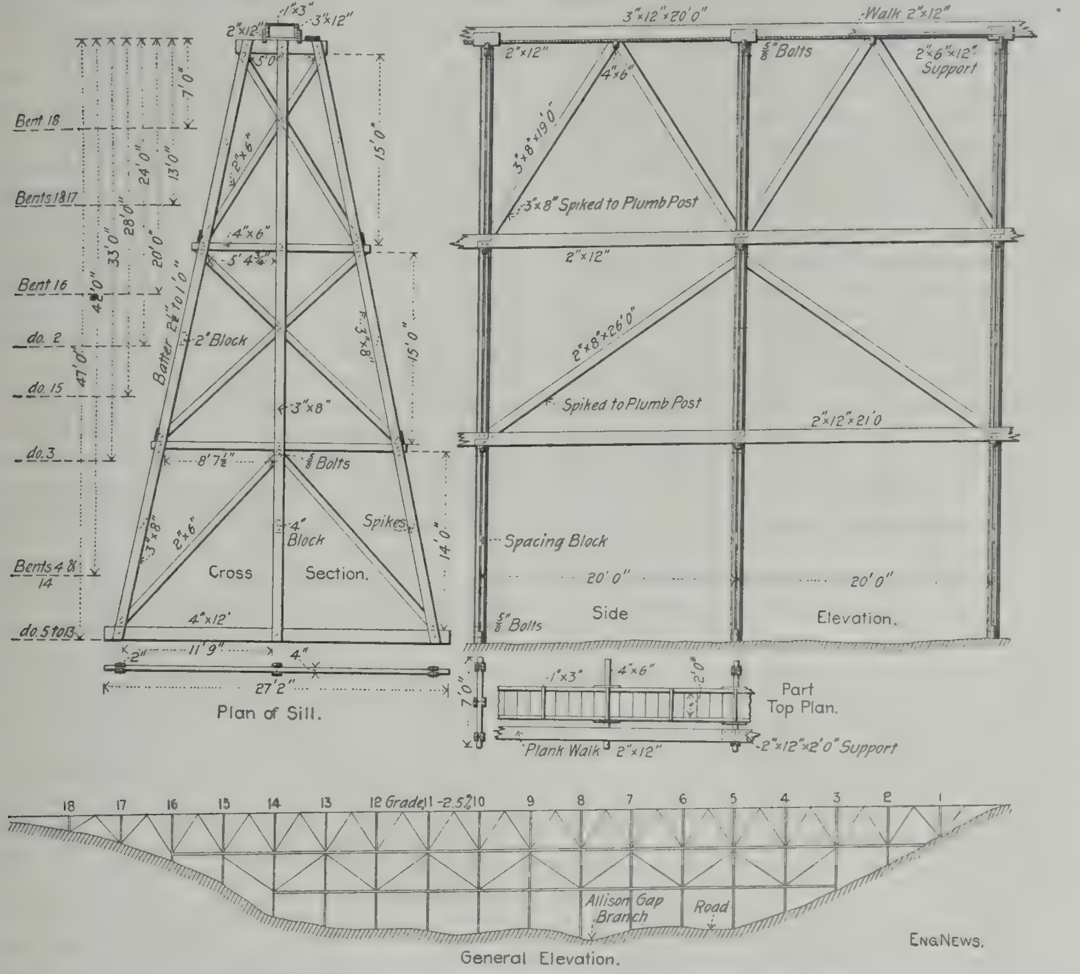


FIG. 1.—DETAILS OF TRESTLE AT MATHIESON ALKALI WORKS, SALTVILLE, VA.
Emile Low, Chief Engineer.

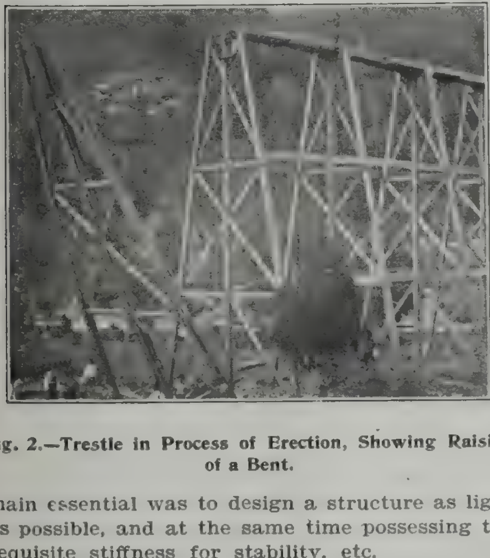

Fig. 2.—Trestle in Process of Erection, Showing Raising of a Bent.

After considering various designs, sizes of timber, length of spans, etc., the accompanying plan, Fig. 1, was finally selected.

The structure as built is 380 ft. long, the central portion being 47 ft. high, for 120 ft. in length. The grade employed is 2.5%. The spans are all 20 ft., measured center to center of bents. The foundations are mudsills, short timbers ranging from 6 to 12 ins. in thickness. Between the bents, where the creek flowed, the foundations were reinforced by rip-rap, to prevent washing and undermining. All the trestle legs were made of 3 × 8-in. stuff, arranged double, and separated by spacing blocks. It will be observed that the spacing blocks for the two batter legs are 2 ins. thick, while those of the vertical legs are 4 ins. thick, this so as to allow room for the double 2 × 6-in. braces, which cross each other at the vertical legs.

In ordering the timber it was in such lengths that bents Nos. 1 to 4, inclusive, and Nos 15 to 18, inclusive, were framed in one length. In bents Nos. 5 to 14, inclusive, the timber for each leg was ordered in two short and two long lengths, these pieces alternating on opposite sides, so that the splice always came near the middle of the long lengths, the joints abutting and being secured by three bolts, of which two passed through the braces, and one through the intermediate cap. This latter is 4 × 6 ins. in size and is dapped 1 in. on each side, at the ends, making the space between the parallel faces of the batter legs 2 ins., corresponding to the thickness of the braces and spacing blocks.

The sills and caps are made of 4 × 12-in. pieces, to secure vertical stiffness. The framing of these is similar to that of the intermediate caps, and is shown in detail on the drawing.

Bolts of ⅝-in. round iron were used in the various connections of the bents, only two lengths being required, 10½ ins. long for the batter legs and 12½ ins. long for the plumb or central leg. The sway or lateral bracing was made of 2 × 6-in. lumber, bolted at the ends and at the intersections. The longitudinal bracing consists of horizontal waling strips, 2 × 12 ins. in size, well spiked to the outside of batter legs. An additional system of inclined longitudinal bracing was used in the middle story, consisting of one piece of 2 × 8-in. lumber for each span. This was secured by spiking to the plumb legs.

The flume proper was planned to be 2 ft. wide and 1 ft. deep. This was modified before construction by making the same 30 ins. wide inside. The sides of the flume were made of 3-in. plank, the bottom being 2 ins. thick, composed of pieces 3 ft. long, and nailed at right angles to the sides. To support the flume at the center, three braces, 3 × 8 ins., were employed, the toes of which rested upon the intermediate caps and these were also well nailed to the center legs, with which they were in contact. The flumes were made in 20 ft. lengths and abutted. The ends of the flumes were secured by a plank 2 ft. long, spiked to the outside ends and dapped down over the caps. Several methods of erection were discussed, and it was finally decided to frame and put each bent together, arranging them in logical order on the ground, and in such a manner that when erected each bent would be in its proper position. It was found that owing to the lightness of the timber employed, the high bents would not possess sufficient stiffness against flexure, and to remedy this to some extent additional temporary timbers were lashed to the legs while in the course of erection. The accompanying photograph, Fig. 2, shows a portion of the trestle in place, and one bent being raised to a vertical position. Placing the flumes in position occupied considerable time, as each section had to be carried out whole on the completed structure, and then projected out over the end of the last finished bent. To facilitate this placing, the last erected bent was allowed to lean towards the working end of the trestle, and as soon as the forward end of the flume was securely attached to the leaning bent, this latter was drawn to a vertical position, drawing the flume with it.

The trestle was not erected without accident. After bent No. 13 had been erected and was being held in position by temporary guys, one of these, composed of two ropes, parted by the slipping of a knot, and the bent fell towards the finished work, carrying down in its fall bents Nos. 12, 11 and 10, which were as yet not stayed nor fully braced. By a singular fatalism, the bent that fell was No. 13. Luckily no persons were injured by the accident, and but little actual damage was done, although the resulting loss of time and expense of erection was considerable.

The total amount of lumber in the structure is about 23,000 ft. B. M., which cost, delivered on the ground, $12.50 per M. ft. B. M. The lumber was all oak. The cost of erection was about $500, which was large. Much of this can be attributed to the difficulty of erecting, as well as to the accident mentioned above.

◆

EXPORTS OF WIRE NAILS from this country have greatly increased during the past three years, and especially during the last year, as is shown by the following figures of the total exports of nails from the United States for four successive fiscal years:

Year ending June 30,	Cut Pounds.	Cut Value.	Wire and all other. Pounds.	Wire and all other. Value.
1896.......	20,730,260	$428,630	8,031,927	$321,055
1895.......	16,895,428	283,646	4,367,267	210,192
1894.......	16,736,643	330,118	3,233,776	180,607
1893.......	15,604,347	330,554	2,300,501	158,093

It is stated that at present American nail makers are beating the German firms in their competition for the trade of Japan, China and Australia, and this in spite of the fact that the Germans have much less freight to pay on the goods shipped to those countries than the Americans.

◆

THE ADVANTAGE OF TRADE STANDARDS in securing export orders is well illustrated by the success of American pipe makers in securing South African orders. The story is told by London "Engineering," as follows:

> The advantages of a set of standards generally recognized in the trade are well shown in the recent orders sent from Johannesburg to the States for iron piping. Formerly this was obtained entirely from the Clyde, but the different makers had all their own standard sizes for couplings, unions, etc., with the result that a batch of such goods received from one Scotch firm could not be used interchangeably with the goods supplied by another. American makers have agreed on a set of standards, to which all work, and for this reason only they are getting a large share of the South African trade. When complaints were made the Scotch firms defended themselves by the inane remark that their own fittings were interchangeable inter se, and they professed to be unable to understand why this was insufficient. Not so very long ago certain makers held similar ideas as to screw threads. In short, they rather thought they scored a point in having their own standards, as they fondly imagined that then all repairs must be returned to them for execution. Experience has, however, shown that a careful colonial importer avoids placing his orders with such firms, as the annoyance of having to send some thousands of miles to replace a broken bolt can only be balanced by a very substantial saving in the original cost of the goods.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; *6 months,* $2.50; *2 months,* $1.00; *Single copies,* 15 *cents. To all other countries in the Postal Union, add* $2.08 *per annum* (4 *cents per number*) *to above prices for postage. No club rates allowed. Mailing addresses may be changed at will by sending both old and new address. We shall be obliged if subscribers who fail to receive their papers promptly will notify us without delay. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number* 326 *means that subscription is paid to the* 32d *week* (*that is the issue of Aug* 6) *of the year* 1896; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: 20 *cents per line agate measure. Want notices, special rates, see page* 22. *Rates for standing advertisements sent on request. Changes to standing advertisements must be in hand on Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

The proposed filtration of Philadelphia's water supply has been again brought to the front by the presentation of a report on the matter prepared by Mr. Allen Hazen, who was engaged for that purpose by the Woman's Health Protective Association. We have briefly summarized this report elsewhere in this issue. The need of a decent water supply for Philadelphia is well known; sooner or later the use of the foul and noxious Schuylkill water must be abandoned, and the sooner this is done the sooner will the annual sacrifice of human lives to the diseases spread by that contaminated water be ended. The question which for nearly a generation has been a mooted one in Philadelphia is what shall take its place? If the plan is adopted of going to some natural stream with abundant flow from a drainage area so far removed from populous towns as to ensure against serious pollution for many years to come, then the only available source of supply appears to be the upper Delaware, and this would mean the construction of a conduit of sufficient size to carry the city's entire supply and nearly 100 miles in length. It is no wonder that the city has hesitated to undertake so gigantic an enterprise.

But within the past few years engineers, and to some extent the general public also, have come to understand the practical possibilities in the purification of water by filtration; and it is quite possible that it may soon be accounted better practice to take water and filter it from a stream more or less polluted that flows past a city's doors, than to go long distances for a potable supply which often in a few years will become polluted. Philadelphia, for example, instead of going a hundred miles up the Delaware for a pure supply can take water from the same stream as it flows past the city, and by the process of filtration can make it as pure as the water of the mountain brooks that feed it. Mr. Hazen estimates the cost of a filtration plant at Philadelphia, capable of furnishing an average daily supply of 195,000,000 gallons, at $3,400,000. It will be seen that this is an insignificant sum compared with the cost of bringing the same amount of water from the Delaware Water Gap, and no one familiar with the actual results obtained in sand filter beds can doubt that it would actually be purer and safer water than that of the river as it flows at the Water Gap, provided, of course, that the filters were so designed and so operated as always to give the maximum degree of efficiency attainable by this process.

◆

We believe the fact is too often lost sight of in making comparisons between a filtered supply for a large city and a supply obtained from a distant watershed, that any stream large enough to supply a great city must at times carry more or less pollution. The watershed of any such stream must have on it more or less farms and villages, the drainage of which will often go directly into the streams unless great expense is incurred in the purchase and foresting of large areas, and their sanitary policing. In the case of such a great area as the Delaware watershed above Trenton, such a task would be practically impossible. Again all such streams are subject to sudden floods, during which great quantities of sediment, road washings, and the flushings of farm yards, pastures, house drains, etc., are carried into the stream and brought down. Should the question become an issue in Philadelphia between going to the Water Gap for a supply and installing a filtration plant, we suggest that those in favor of the latter take their opponents on an excursion to the Water Gap at a time when the river is in flood.

Whether Mr. Hazen's estimate of the amount of supply required and the cost of the filtration plant to furnish it are correct or not, it is at least fairly certain that the Philadelphia supply could be filtered for a small part of what it would cost to bring water from the Gap, or for that matter from any of the other sources which have been considered at various times.

The remarks Mr. Hazen makes with respect to the waste of water in Philadelphia are excellent. It is generally understood nowadays by all water-works engineers that the way to reduce waste of water is to install meters; but with the mud and grit and culm which Philadelphia water carries, any water meter is bound to wear more or less; and when a water meter becomes so worn as to lose its sensitiveness, so that it does not register the small flows due to leaky fixtures, a large part of its value as a means of preventing water-waste is lost. On the other hand, as soon as filtered water is distributed in Philadelphia, meters could be generally introduced, with a certainty that accurate registration and durability and freedom from repairs would be assured. By this means it is quite certain that the water consumption of the city could be reduced to a reasonable figure, and the saving made in this way would go far toward paying the cost of maintenance of the filter beds.

◆

We publish on another page an abstract of the report of Mr. R. S. Hale, Expert to the Steam Users' Association, on Steam Boiler Practice in Europe, which will be of interest to steam engineers. In the types of boilers used there appears to be a great diversity in the different countries. For instance, in England the Lancashire, Cornish and similar types form 61% of the whole number of boilers used, while in France only 12.9% of the boilers are of this type. The externally fired cylindrical, including the elephant boiler, is most common in France, 57.3% of all the boilers being of that type, while England has only 6.8%. England uses 16.6% of small verticals, while France uses only 3.6% and Germany 5.0%. Germany uses 17.3% of locomotive boilers, France only 5.1%. In the United States the plain externally fired multitubular boiler is the most common, but in England it does not appear to be used at all, while France uses 13.4% of that type. We regret that Mr. Hale did not procure statistics showing what kind of boilers had been purchased in the different countries say within the last ten years. We have no doubt that if such figures could be procured they would lead to different conclusions than those which may be obtained from the table given. The boilers now in use in Europe are to a great extent survivials from a past generation. Boilers often last 30 or 40 years, especially in England, where they are well taken care of. The Cornish and other single flue internally fired boiler, which forms 23.7% of the existing boilers in England, is certainly a survival, as is the elephant boiler in France, and the two-flue externally fired boiler in this country. Neither one of these types would now be adopted in a new plant designed with proper consideration of economy of space and of fuel.

A careful reading of Mr. Hale's report will show that Europe is by no means ahead of this country in steam practice in any particular, except in the use of superheated steam. Mechanical stokers are in more general use abroad than here, but they are rapidly being adopted here.

In boiler economy it appears that Europe is neither ahead of nor behind us. From 60 to 80% of the heating value of the coal is obtained in good practice both here and abroad, and the difference of 20% in the practice of different plants is not yet satisfactorily accounted for. In attempting to make a "heat balance" in boiler tests in England, as much as 15% of the heat has sometimes to be set down as "unaccounted for." In order to find the truth about the 5% to 15% of heat thus lost Mr. Hale is now conducting some experiments on a boiler in the vicinity of Boston. Mr. Edward Atkinson, president of the Steam Users' Association, in an introduction to Mr. Hale's report, states that with the completion of this work "the present undertaking may end, unless suggestions be made for the continuance of this service in some form after the present year."

◆

We regret that after all of Mr. Atkinson's attempts to improve the knowledge of steam engineering in this country his labors in this direction are apparently about to come to an untimely end, in fact just as the real work is about to begin, for the several circulars requesting information from subscribers which the Association has sent out, the compilation and publication of the returns, and Mr. Hale's trip to Europe have all been but preliminary to the work which may lead to an answer to the question "How may we improve our boiler economy?" In Engineering News of July 18, 1895, we gave an account of the work which Mr. Atkinson then proposed to do. He then thought that "the manufacture of steam as a separate art may be better comprehended in Great Britain than in this country" and he proposed to set two experts at work, one of them in Europe, to develop "rules for the manufacture of steam in the safest and best manner." The result of the investigation thus far has been to show that Mr. Atkinson was mistaken in his supposition that Europe was in advance of this country in the "manufacture of steam," and there does not seem to be any probability that the experiments on a boiler in the vicinity of Boston that are yet to be conducted will lead to any conclusions from which may be developed "rules for the manufacture of steam in the safest and best manner." It is too bad that "the present undertaking may end unless suggestions shall be made for its continuance." We, therefore, venture a suggestion. The work which Mr. Atkinson attempted to do is a most valuable one and it should be continued, although by different methods. There is an enormous waste of fuel in this country in the average (not in the best) steam boiler practice, and especially where bituminous coal is used. Mr. Atkinson is a great friend of Southern enterprise, and especially its great exhibitions. At the Tennessee Centennial exhibition next year there will be a fine opportunity to make competitive tests of steam appliances. Let Mr. Atkinson organize a bureau of tests of steam boilers, of smoke consumers, of boiler furnaces, mechanical stokers and the like, which shall test every appliance of that nature in the exhibition. We also make another suggestion. His experts have reported, and we believe correctly, that all types of boilers if properly designed and run give practically equal efficiency. It is not tests of different types of boiler that are now needed, but of different kinds of furnace under the same boiler, with different kinds of coal and different methods of firing. Let him try to solve this problem: "Given a 200-HP. water-tube boiler, and six different kinds of coal of widely different qualities, what kind of setting, what method of firing, what force of draught and what size and kind of grates are required to produce the best results with each of the different kinds of coal?" If Mr. Atkinson will now collect funds to pay for an investigation which will lead to the answer of this question he will advance the science of steam making to an extent far beyond anything that could be expected from the methods he has hitherto adopted.

◆

In connection with the coming use of motor-carriages the construction of the wheels is very important, and the notes upon the relative traction values of iron, pneumatic and full rubber tires, given in another column in this issue, are useful and interesting. The pneumatic, full rubber and the iron tire, so far as the effort of traction is concerned, have relative values, in round numbers, of 100, 130 and 133, showing a general economy for the pneumatic of about 30%. But besides this economy in power required there are other and important advantages in the use of the new wheel; and these are the reduction of the effect of sharp shocks and the marked decrease in noise and the wear and tear on the vehicle itself. As to this feature of noise, it may be remarked that the pneumatic tire on a low wheel of the bicycle type is now quite common among the cabs of Paris, and over the smooth wooden or asphalt roadways of that city these tires make so little noise that, for the safety of pedestrians, an ordinance has been passed requiring the owners of cabs to put bells upon their horses. In this way, while the rattle of carriage wheels is much reduced, the jingling of bells is substituted for it. But the person using the carriage gains decidedly in comfort, and the low wheels have advantages in getting into and leaving the vehicle. As shown in the cut reproduced, the wearing part of the rim is heavily armed with rubber and inquiry failed to find any cases of punctured cab tires. The fact that pneumatic tires were actually used fifty years ago, and that they practically differed very little in construction from those now placed upon carriages, will be new to many of our readers. But just as the bicycle, or velocipede, was introduced over seventy years ago, and then laid aside and forgotten, so the condition of our streets and highways, in 1846, was not favorable for the improved carriage tire of Mr. Thomson. The modern development of the bicycle, and now the motor-carriage, is a direct resultant of the improvement of our roads; and good roads and more of them will always be an important factor in the growth of all efforts towards cheaper and more rapid transit upon them.

◆

HOW CAN BETTER BUILDING INSPECTION BE SECURED?

The collapse of a building under construction in New York city on Saturday last calls attention again very forcibly to the fact that building operations in every city need to be very carefully watched in the interest of public safety to prevent careless and wilfully bad work being done. This is by no means the first time that such a disaster has occurred in New York city, and in some of these cases its Building Department has been held partially responsible on account of the careless or dishonest manner in which its duties were discharged under former administrations. In the recent disaster it is clear that serious defects and violations of the building law existed in the structure and were not discovered by the Department's inspectors; but on behalf of the Department it is said that the funds available do not permit the employment of a sufficient force of inspectors to prevent violations of law and bad work. Each inspector is said to have from 90 to 150 new buildings under his charge, and it is manifestly a physical impossibility for him to keep such close and continual watch on each of these as to certainly detect defects and unsafe work.

Another instance of defective construction was recently discovered by Philadelphia's Building Department. A row of 16 new houses was condemned by it, but the owners protested, and in response to their request the Director of Public Safety appointed a special committee to examine the houses and make a report thereon. The following is quoted from this report:

> Walls not plumb, and in some instances cracked; 9-in. party walls, where there should be 13-in. walls. Front walls not tied to party walls in either first or second stories; bricks laid without joints being flushed up, or cross joints put up, and in many places without any mortar whatever. Lintels not used properly, and in many cases there are no lintels at all over the frames. Flue linings not used properly. Inferior joist and roof rafters, in some cases being too short, and spliced out with 1-in. boards. Chimneys lathed and plastered over, also heat pipes. The heat pipes have been run without protection to woodwork or studding. The chimneys are not tied into the walls. The walls in some cases are composed largely of bats. These houses are, in our opinion, dangerous, and have no redeeming features, and we advise that they be torn down to the foundation walls and the foundation walls examined before rebuilding commences.

These two notable cases of defective construction, with others that are occurring from time to time in other cities, should call attention to the question what can be done to more certainly detect defects and unsafe construction.

For many years past more and more responsibility has been laid on the city building bureaus; the building laws have been made more and more complex and detailed, and reliance has been placed upon the official inspectors to see that the laws are carried out. We have no word to say against this tendency and consider it emphatically the duty of every city and town to see that the buildings within its limits are so constructed as to afford reasonable safety to their occupants and reasonable security against the spread of fire. But at the same time it appears to us that this inspection by public officials should not be allowed to take the place of a systematic inspection by the owner or his agents during construction.

Let us take the case of New York city. If we are correctly informed, the total amount expended in new buildings and alterations of existing structures is about $90,000,000 per annum, while the total appropriation for the annual expenses of the city's Building Department is $265,000. Probably at least a third of this sum is expended for the office employees, who examine plans filed with the Department, and in general office expenses, superintendence, etc. This leaves about $177,000 to pay for actual inspection of buildings, or roughly, about one-fifth of one per cent. of the total expenditure on construction. Any engineer or architect can easily see that this is far too small an allowance to ensure a thorough inspection. On the simplest class of civil engineering works, such as bridge pier or retaining wall construction, an allowance of ½ to 1% for inspection would not be excessive; and manifestly a much larger amount should be expended for inspection of ordinary building construction; if good work and strict compliance with specifications is to be ensured. On the other hand, of course, the city building inspector need only concern himself with matters of safety, which somewhat simplifies his task. We believe it will be generally agreed, however, that an expenditure of not less than a half of one per cent. of the annual outlay on buildings is necessary to enable a city to inspect properly the construction work going on within its limits.

It appears, therefore, that allowing every city building department to be honestly and efficiently managed and every one of its inspectors to be absolutely honest and faithful, it is still certain that with the limited appropriations which are generally allotted to city building departments, their inspection must be too hasty and incomplete to ensure discovery of every defective building, even though they may usually succeed in doing so. The time may come when this will be remedied—when ampler means will be furnished to building departments for their work; but it should be fully understood that under existing circumstances, the inspection made by the city should never take the place of or relax the vigilance of the inspection that should be carried on on behalf of the owner.

It is in this class of inspection that a great opportunity for improvement exists. The best architects, conducting a large and well-systematized business, have efficient corps of inspectors; but on the great bulk of building construction carried out under the direction of ordinary architects, or in many cases without the aid of any architect, inspection is too often a very cursory affair.

That this should not be, goes without saying. The owner of a building is responsible for its safety. If it falls because of bad construction and death or injury result to the inmates, he can be held for damages. Further, most insurance policies contain a clause making them null and void in case of the fall of the structure which they cover. The owner of a building who neglects to provide inspection to ensure its safe construction, therefore, runs a heavy risk. Besides this, an expenditure for inspection will mean in many cases a more durable structure, one which will involve less expense for repairs for many years. The owner, therefore, who, to save money, neglects to secure inspection of the structure he is building is saving at the spigot and wasting at the bunghole.

It has seemed to us in considering this question of building inspection that there is an opportunity here for the establishment of enterprises similar to the inspection bureaus which have made so pronounced a success in the examination of iron and steel, bridge work, etc., or those which cut so prominent a figure in marine architecture. Once let such a bureau acquire reputation for integrity and thoroughness and its services would be everywhere in demand. At present the purchaser of a building has no adequate assurance that the structure is soundly and securely built. Any such purchaser would pay somewhat more for a structure if with the deed he received a certificate of an inspecting bureau of wide reputation that the structure had been continuously inspected during its construction and had received approval. Moreover, when it became customary for purchasers to ask for such certificates, builders who erect houses to sell, as well as owners building for their own occupancy or for investment would find it to their advantage to employ such a testing bureau. Financial institutions, also, would demand such a certificate as precedent to granting a loan upon the structure.

It can easily be understood, moreover, that such a bureau could perform the work of inspection more efficiently and economically than the ordinary architect. It could, for example, have special men to inspect machinery, lighting apparatus and other special details of the work with which the average architect or his assistants are often not familiar. Thus many architects would prefer to place the inspection of their work in the bureau's hands rather than undertake it themselves.

We have outlined the above merely as a suggestion of what seems to us to be a hopeful plan for the improvement of the character of buildings; and we hope that some of the engineers and architects who have made a success of the inspection of metal construction may see their way clear to undertake work in this larger field.

◆

LETTERS TO THE EDITOR.

Civil Service Examinations.

Sir: I desire to inform you that there will be an examination for the position of Plumbing Inspector by this Board on Thursday, Oct. 8, beginning at 10 a. m., and will be greatly obliged if you will insert notice of such examination in your journal. Applications will be received only from residents of the State of New York.

Yours respectfully, S. William Briscoe,
Secretary New York City Civil Service Boards.
New Criminal Court Building, New York city,
Sept. 25, 1896.

◆

Water Development on the Mojave River, near Dagget, Cal.

Sir: I wish to call attention to an apparent error, referring to my article in Engineering News for Sept. 3, 1896, "Water Development on the Mojave River." The last sentence of the first column, page 159, reads: "In this case, where the sheet piling brings the water plane constantly above the flume grade, it would seem that the gathering flume might have been dispensed with."

I have no copy of my manuscript here in camp, so I cannot now compare, but I presume the sentence was originally written as follows: "In this case, where the sheet piling brings the water plane constantly above the flume grade, it would seem that the floor of the gathering flume might have been dispensed with."

Yours truly, J. B. Lippincott.
Strawberry, Cal., Sept. 16, 1896.

Water Tigers and Water Supplies.

Sir: When cleaning out a distributing reservoir here last May there was considerable alarm manifested over the presence of numberless worms covering the entire sediment at the bottom of the reservoir. It was feared that they might be permanent inhabitants of the water and liable to continual distribution through the service pipes of the city.

Specimens submitted to an entomologist, however, were pronounced to be the larvae of the so-called water tiger belonging to the caleroptera. Among them were the hydrophilidae, gyrinidae, dytiscidae, etc. They are reported to have a remarkably rapid transition from this form to the next, which is that of the flying beetle. It is said that it deposits on the water the eggs from which these larvae are produced; also that it is not injurious to water for domestic use, and in fact is a scavenger in the water, tending to purify it rather than pollute it.

Their presence in the water is of such short duration that their discovery was accidental. A question arises as to how often our drinking water is similarly inhabited.

I would like to ask if this is a common experience, and if so what influence this insect really has on the quality of the water? If harmful, what is the usual treatment?

Respectfully, H. B. Patten, City Engineer.

Cheyenne, Wyo., Sept. 14, 1896.

(We do not recollect a similar instance, and should presume that the authority consulted was right in pronouncing the visitors entirely harmless.—Ed.)

Cost of Testing Steel Tapes.

Sir: In the Sept. 24 number of your valuable journal, under the caption of "Testing Steel Tapes," the statement appears that our charge for testing a steel tape of 100 ft. is $25, and we are at a loss to understand how such an erroneous impression originated.

The facts are as follows: We charge only 50 cts. for comparing with our standard the whole length of any tape of 100 ft. or less, and 10 cts. additional for each intermediate graduation actually tested. We compare many tapes from all parts of the country, and sometimes from other countries, and frequently the total length only is desired, the total charge in that case being only 50 cts. If both sides are graduated, one in feet and the other in metric measure, and both are tested, the charge of course would be doubled. It is seldom that a test of more than ten of the intermediate graduations is called for, and the additional charge in that case would only amount to $1. The amount of work expended on a tape, therefore, depends on the wishes of its owner.

It has always been the policy of this office to make the charges for such work merely nominal, and in view of the great importance of this matter to engineers, surveyors and others, we trust you will insert in your next number a correction of the statement above referred to.

Yours respectfully, W. W. Duffield,
Supt. U. S. Coast and Geodetic Survey.

Washington, D. C., Sept. 29, 1896.

(We are pleased to make the above correction and are sure that many engineers will be interested to learn that they can have their tapes verified at so trifling a cost. We were misled by a statement made before the Ohio Society of Civil Engineers and Surveyors in discussing the testing of tapes.—Ed.)

Sir: Following the inquiry by Mr. Erlandsen in reference to testing steel tapes, the writer wishes to call attention to an experience in this line showing a discrepancy between the United States standard tests at Washington and the method employed for testing by at least one prominent tape manufacturer.

The tape in question was received from the manufacturers as being 300 ft. long. It was at once sent to Washington, and by the Department of Standard Weights and Measures reported to be 0.52 in. long under a pull of 10 lbs. When the attention of the manufacturer was called to this, they at once claimed that 10 lbs. was more tension than the tape should have when supported throughout its length, and that their own tests were made under a pull of 2 lbs. This at once explained the difference in length.

The question then arises, why should a manufacturer assume a method for testing steel tapes which is known to differ from that employed by the Department of Standard Weights and Measures? Assuming that their standards for comparison are of the same length, the tapes manufactured and sent out by them must always exceed the U. S. standard length when tested by the Department at Washington.

It would be interesting to know if it is common practice for manufacturers of steel tapes to each make and test his work as his own individual ideas would suggest and to send these tapes out as being of correct length.

Yours truly,
Edwin D. Graves, Assoc. Am. Soc. C. E.

Hartford, Conn., Sept. 29, 1896.

A Stand-Pipe Failure at Garden City, Kan.

Sir: A brief note in regard to the failure of the Garden City stand-pipe, another addition to the already large number of failures of these structures, may be of interest to the readers of Engineering News.

This stand-pipe was built by Palmer & Son, of Kansas City, Mo. It was located about one-fourth mile from the Arkansas River, and a few feet above its bed. It was 10 ft. in diameter, 130 ft. high, and was supported on a masonry foundation on a level with the surface of the ground. It was held in place by six 1½-in. bolts through six cast-iron brackets, and by six 1-in. wire guys fastened to masses of masonry 65 ft. from the pipe and to an angle iron 90 ft. above the base. The plates of the top course were ¼, and of the bottom course ½-in. thick. The vertical joints were double riveted and the horizontal joints single riveted, with ⅞-in. rivets. The structure was stiffened by five 3 × 3 × ⅜-in. horizontal angles, to one of which, 90 ft. from the base, rings were welded to hold the guys. The bottom plates were ½-in. in thickness, and were connected to the first course by 4 × 4 × ⅝-in. angles. The brackets were cast iron, legs 2 ft. long, fastened to the structure by ten rivets, and to the masonry by 1½-in. bolts.

About four years after erection a crack appeared on the west side of the pipe, in the angle iron connecting the bottom to the first course. This was soldered but continued to leak and about 2½ years before the failure a new piece of angle, about 5 ft. long, was put in. Four of the six brackets had their legs broken about this time, and were repaired by bolting to them a strap of iron which passed down around the anchor bolt.

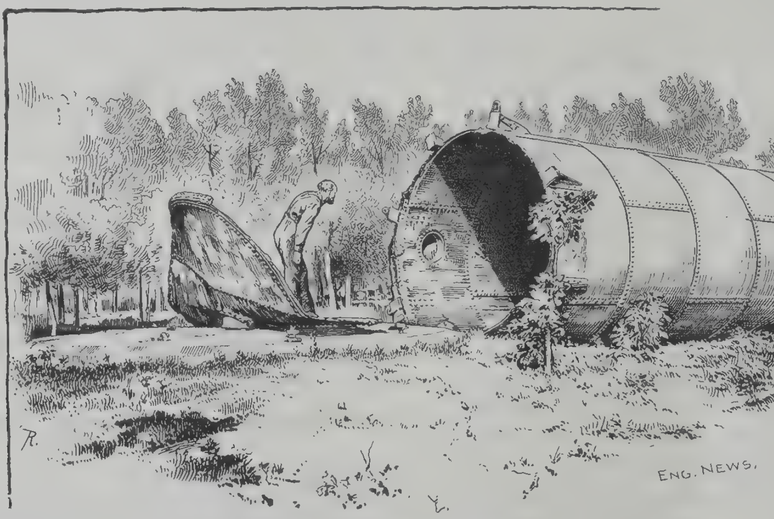
On April 30, 1896, during a very high wind from the northwest, estimated to have a velocity of 60 to 70 miles per hour, with occasional gusts of 90 miles, and which wrecked many of the windmills in this vicinity, a crack appeared on the north side of the bottom angle iron. This crack increased in size for 1¼ hours, until it was 5 ft. long, with the water rushing out rapidly. Suddenly the angle iron to which the north guy was fastened gave way and the pipe blew over in the southwest direction. The pipe was about one-fourth full at the time of failure, with both pumps delivering into it at nearly their full capacity.

The bottom angle iron broke at the angle all the way around, except where the new piece was put in, where the first course failed along the rivets. All the brackets were broken, and the bottom was broken somewhat at its center around the entrance pipe.

It seems quite clear that the failure was due to three causes: (1) The weakness in the angle iron connecting the bottom and first course; (2) to the brackets not being long and strong enough; and (3) to the fastening of the guys being weak.

E. C. Murphy,
Hydrographer U. S. Geological Survey.

Lawrence, Kan., Aug. 31, 1896.



AN OVERTURNED STAND-PIPE AT GARDEN CITY, KAN.

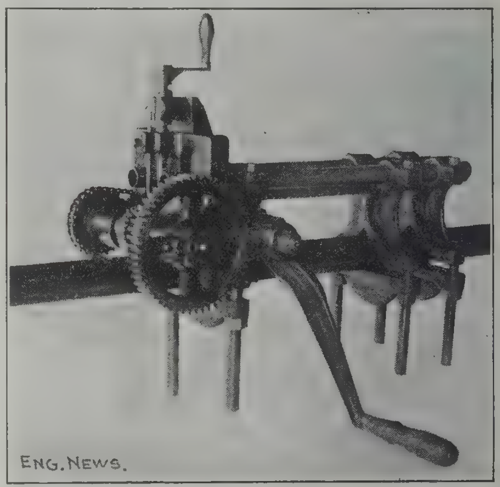
Notes and Queries.

T. W., Philadelphia, Pa., asks for a reference to some paper or publication on the construction of switch-back railways and of toboggan slides, as he has received a request on the subject from Japan and is anxious to supply the information desired.

The Paul Boynton Co., of New York, has patents on toboggan slides or chutes for boats to run down into a sheet of water, but we do not know the builders of any of the switch-back railways to be found at all pleasure resorts in this country.

A PORTABLE KEYSEATER.

The illustration herewith shows a portable keyseater, for cutting keyways in long shafts, manufactured by Messrs. John T. Burr & Son, Kent Ave. and South Sixth St., Brooklyn, N. Y. As shown in the cut the machine is clamped on the shaft and operated by hand. It will cut keyseats in shafting up to 5 ins. diameter, and will cut for 12 ins. in length without resetting. The cutting is done by milling cutters, and the machine is geared so that three revolutions of the crank produce one of the cutters. An automatic power-feed is provided, which can be instantly disengaged, and the machine fed by hand if desirable. A keyseat ¾ × ⅜ in. can be cut at one operation; for wider cuts the work is gone over more than once. A laborer can cut a keyseat ⅝ × 5-16 × 12 ins. easily in an hour. Larger size machines are also built to be operated by electric motor or by belt.



Portable Keyseater. Manufactured by John T. Burr & Son, Brooklyn, N. Y.

FILTRATION OF THE PHILADELPHIA WATER SUPPLY.

A vigorous crusade against the further use of Schuylkill River water, without filtration, is being led by the Woman's Health Protective Association of Philadelphia, and the subject is being actively discussed by the press of that city. All admit that the present supply is impure, and that the water from this river is blackened with coal dust or made yellow by mud at every high stage in the river, and that it is liable to contamination from six cities upon its banks above Philadelphia, whose aggregate population is 350,000. An entirely new supply, from a distant source of permanent purity, is undoubtedly the most attractive solution of the difficult problem presented, and for years past extensive surveys and investigations have been made with that end in view. But the enormous cost of such an undertaking, coupled with the lack of available means in the City Treasury and the disinclination to permit a private company to control the water supply of Philadelphia, have so far prevented any of the many projects of this sort which have been brought forward from being carried out.

Filtration has been often suggested, in Philadelphia. Several years ago certain parties backed by the city press, seriously recommended the location of filter-beds or filter-galleries in the River Schuylkill itself, an absurd scheme, which was dropped as soon as computations were made of the area required for the quantity of water to be filtered, the cost of construction, and the difficulties and risks of maintenance. But since the success of sand filtration as a means of purification of water has become generally understood, the intelligent citizens of Philadelphia have become strongly in favor of the construction of a system of filter-beds. Our readers will recall that an appropriation to build a single filter-bed was before the Philadelphia Councils some months ago, and was only defeated by a close vote.

Recently the agitation for filtration has been started anew by the publication of a report upon the project of filtering the city's water supply made to the Woman's Health Protective Association by Mr. Allen Hazen, of the firm of Hazen & Noyes, of Boston.

This report has now been submitted to the Mayor by the Association, and the recommendations are about as follows: Mr. Hazen figures upon a population of 1,300,000 in 1900 and a per capita supply of 100 gallons per day. He admits that the maximum consumption now reaches 150 gallons per head per day, at times, but he believes that this could be reduced to the amount stated by the increased use of meters and by closer supervision of the daily consumption. He thus assumes a total filtering capacity of 195,000,000 gallons daily as ample for all purposes, with a reasonable system for the sale of water. He also assumes upon present European practice that the average daily yield for each acre of effective filtering area, of the character proposed, would be 2,000,000 gallons, for all seasons of the year and including the time the beds are out of service for cleaning. He figures that at times of maximum consumption 50% more water will be used than the average of the year; and at such times the filters may be operated at the rate of 3,000,000 gallons per acre daily. If this is not sufficient for these emergencies, the deficiencies can be made up by drawing upon the reservoirs.

The filters proposed are the ordinary sand filters, similar to those used at London, Hamburg, Altona, Liverpool, Amsterdam, Rotterdam and other cities, and in this country at Lawrence, Poughkeepsie, Mt. Vernon, Nantucket and elsewhere. These consist of water-tight basins, with masonry sides; the water-tight pavement carrying upon it underdrains surrounded by gravel and supporting a layer of sand. The water will be brought over the sand and filter downward, and would be collected in the gravel and carried by the drains to the reservoirs or to the pumps; a suitable regulating apparatus being placed at the outlet of the drains for controlling the rate of filtration and loss of head. Mr. Hazen would build the walls of the filters of brick, or rubble-masonry lined with brick, and would probably use concrete for the pavement with a thin water-tight covering of asphalt. He does not consider that the climatic conditions would require covering the filters; nor does he consider settling basins an essential for Delaware River water, but he believes this preliminary treatment would be desirable for water taken from the Schuylkill River. His plans contemplate for each set of basins, a receiving basin into which the water would be pumped from the river and from which it would flow to the filters. These receiving basins would hold one-fourth of a day's supply and the sedimentation which would take place in them would probably be sufficient. The Schuylkill River, he says, is ordinarily comparatively clear, and could be filtered without previous sedimentation. And as the high water turbidity rarely occurs at the time of maximum consumption, the filters would usually operate upon this water at a rate below the maximum.

According to a map presented with the report, Mr. Hazen proposes to establish these filters as near as possible to the Belmont, Roxsborough, Spring Garden, Queen Lane and Frankford pumping stations, with filtering areas ranging from 5 to 30 acres at each point, and with an average filtering capacity of from 10,000,000 to 60,000,000 gallons daily. The approximate cost of supplying 195,000,000 gallons daily of filtered water is placed at $3,400,000, and the cost of operation is estimated at $3.50 per million gallons of water filtered; or $166,075 annually for the amount stated. Mr. Hazen also suggested that when larger quantities of water were required it would be possible to obtain this supply from the Delaware River by means of filtration, and to use it in connection with that furnished by the present pumping stations. In this way a practically unlimited supply could be secured, at least 1,000,000,000 gallons per day being available.

Mr. John C. Trautwine, Jr., Chief of the Water Bureau, in speaking of Mr. Hazen's plan, said that the city is now consuming about 225,000,000 gallons daily, and unless steps were taken to stop the present great waste of water Mr. Hazen's filtering capacity, and the cost of the plant, would have to be doubled.

The consideration of the merits of the two water sheds as gathering areas for a city water supply was a feature of Mr. Hazen's report. The Schuylkill River, above the water intakes, has a drainage area of 1,900 sq. miles and the population upon this water shed, above Philadelphia, is 350,000, or about 185 persons per square mile. The Delaware River, above the city intakes, has a drainage area of 8,100 square miles with a population, in 1890, of about 600,000, or an average of 74 per square mile. Yet 94% of the present Philadelphia water supply comes from the Schuylkill basin, and only 6% from the Delaware River. Mr. Hazen also pointed out that the existing eleven reservoirs in the Philadelphia supply have a nominal aggregate capacity of 1,400,000,000 gallons, equivalent to about seven days' supply at the present rate of consumption; but owing to the defects in some of these reservoirs the actual aggregate storage is about 1,000,000,000 gallons, or five days' supply.

TEST OF A FIREPROOF FLOOR.

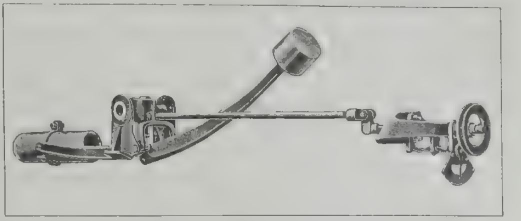
In our issue of Sept. 17 we described the tests which are being made by the Department of Buildings of the City of New York to determine the resistance to fire and water of various systems of fireproof floors. The third test of the series was made on Sept. 29 at the testing ground at 68th St. and Avenue A. The floor was built by the Central Fireproofing Co., of No. 874 Broadway, New York city, and was of the ordinary construction of 10-in. iron beams set 4 ft. apart, with the spaces filled in with 10-in. cellular blocks of porous terra cotta set endwise. The lower flange of the beam was protected by a 1-in. tile carried by projecting flanges of the adjacent blocks. The construction was identical with that used in the new building of the Corn Exchange Bank, the blocks being part of the lot made for that building. Two sections of the floor were loaded with brick to 150 lbs. per sq. ft. and a fire of cordwood was started at 9 a. m. in the brick room of which the floor formed the roof. In about an hour a temperature of over 2,200° F. was reached. The fire was maintained for six hours when a stream of water of 60 lbs. pressure from a fire engine was thrown into the room and against the underside of the floor. The result of the sudden cooling of the hot terra cotta blocks was to crack the lower portions of some of them, but at no point was there a hole broken through, and the floor continued to support the load of 150 lbs. per sq. ft.

◆

AN AUTOMATIC FEED WATER REGULATOR FOR STEAM BOILERS.

We illustrate herewith an automatic feed-water regulator for steam boilers, which has been placed on the market by Messrs. J. J. Thornycroft & Co., of London, builders of the well-known Thornycroft water tube marine boiler. This regulator entirely avoids the common objection to instruments of this class, viz.: that they have moving parts passing through stuffing-boxes, which are apt to give trouble by their friction whenever the packing is tightened. Its principle is similar to that of the ordinary ball cock used on house cisterns. A float formed of solid drawn steel causes a lever to rise and fall with the water level and so to shut or open a valve placed inside of the boiler, which controls the admission of feed water.

The important novelty in this regulator is the method adopted for enabling the float to be adjusted to stand at a definite height, although the amount of valve opening required to admit sufficient feed water varies with different rates of steaming. This is done by mounting the fulcrum of the float-lever on one arm of a bell crank, the position of which can be adjusted by a rod which passes through a stuffing-box in front of the boiler and which is provided with a screwed end. This rod can be moved to and fro by the screwed hub of a hand or chain wheel. An index to show the rate of working for which the position of fulcrum is adjusted completes the apparatus. Messrs. John Platt & Co., 97 to 103 Cedar St., New York, are agents for the United States.



Automatic Feed-Water Regulator. Manufactured by J. I. Thornycroft & Co., London.

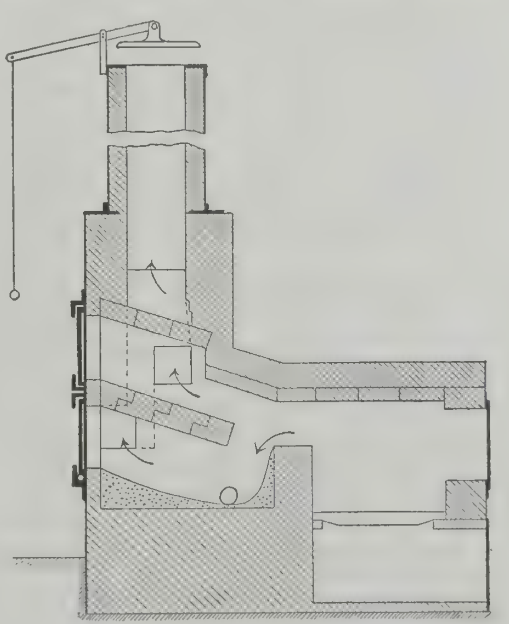
THE GARRETT BRASS-MELTING FURNACE.

We illustrate herewith a style of brass-melting furnace, known as the Garrett furnace, which is being introduced by Messrs. J. W. Bennett & Co., engineers and contractors, 714 Lewis Block, Pittsburgh, Pa. In it crucibles are dispensed with, and at the same time the furnace is quite different from the ordinary reverberatory furnace. The metal is charged in the upper chamber shown in the cut, which is separated from the lower, or bosh, by a sloping fire brick arch. When the metal is heated it is pushed forward on the arch, and when it melts it drops down into the lower chamber out of reach of the oxidizing influence of the melting flame. The bottom of the bosh is lined with ganister, and it slopes toward the tapping hole. The furnace may run continuously, and it is claimed that in continuous use the bottom will last from five to to seven weeks without repair. The upper and lower chambers are each connected with the flue by fire-brick dampers, by which the heat in either chamber may be regulated. If the melted metal in the bosh becomes too cold it may be heated by opening the damper leading from the bosh and causing the flame to traverse through it. A furnace of 600 to 800 lbs. bosh capacity, capable of melting 5,000 to 6,000 lbs. daily, occupies a space of 30 to 40 sq. ft. The loss by oxidation in this furnace is said to be no greater than it is in melting in crucibles.



Section of the Garrett Brass-Melting Furnace.

THE WATER POWER AND ELECTRIC TRANSMISSION PLANT OF THE BIG COTTONWOOD POWER CO.

By W. P. Hardesty, C. E.

(With inset.)

The water power and electrical plant of the Big Cottonwood Power Co. is situated on the creek of the same name in Salt Lake county, Utah. This stream has its source in the high mountains of the Wasatch Range in the eastern part of the county, heading next to the summit and divide between Salt Lake and Summit counties, and after flowing in a general westerly course for about 16 miles it emerges from the mountains onto the broad Salt Lake Valley. The creek is fed at its head by several fine lakes, of which Silver Lake is the largest and farthest down. From here, at an elevation of about 9,000 ft. above sea-level, the fall to the mouth of the canyon is about 4,000 ft. The creek gathers volume from its numerous small tributaries, and by the time it leaves the mountains has attained a size that, for eight months in the year, would justify calling it a river. The great fall of this stream, together with its large and reliable flow of water combine to render it peculiarly fitted for water power purposes.

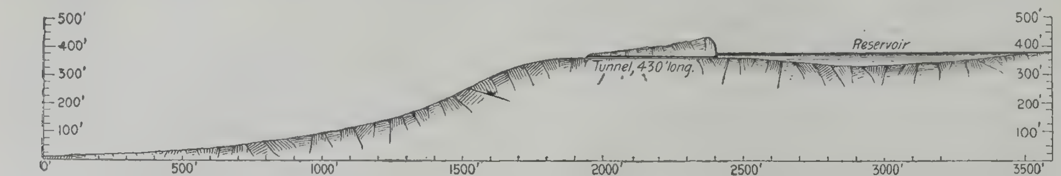


FIG. 7.—PROFILE OF PIPE LINE OF BIG COTTONWOOD POWER PLANT.

The map, shown in Fig. 1, of about nine miles of its lower part, including over one mile entirely out of the canyon, shows the course of the creek. Depending for its supplies for uniform and effective flow entirely on the melting snows or their results, never-failing springs, the stream is quite reliable for the production of water power. About three miles above the mouth of the canyon, begins a steep ascent producing what is known as "The Stairs." Here the rise is 200 ft. in one stretch of a little over ¼ mile, or the "Stairs" proper; nature has done much moreover in rendering this a peculiarly well fitted site for the production of power by having caused the creek to make a wide detour on account of a huge slide from the mountains having at some time pushed it across the canyon at this point, partly gorging it and raising the upper levels, and at the same time leaving a low neck or divide on the slide so as to permit water to be carried directly across it and save following the canyon in its horse-shoe curve.

The great advantages of this portion of the canyon for the production of water power, being only 14 miles from Salt Lake City, were first realized by Mr. R. M. Jones, the engineer and manager of the project about to be described.

In September, 1891, he located and appropriated the waters of this part of the creek for power purposes, and at once went to work on his project. Work was done on a small scale until November, 1893, when the Big Cottonwood Power Co. was organized, since which time the undertaking has been carried forward to completion. This development, called the "Stairs" Division or Plant of the company, consists essentially of a reservoir for storing water, a delivery pipe, so arranged that water can be taken either from the reservoir or the creek itself, leading down to the power house. The map, Fig. 1, shows the location of all parts.

Reservoir.

The minimum flow of the creek at the reservoir during the low water season is 3,400 cu. ft. per minute, and for eight months of the year is 5,000 cu. ft. The theoretical horse-power thus obtainable, with the static head of 380 ft. at the power house, is 2,450 and 3,600 respectively.

On account of the varying amount of power demanded at different hours of the day by the concerns it was intended to supply with power, it was decided to build a storage reservoir with a capacity for 12 to 24 hours supply, thus storing for maximum consumption, during the hours of the day when the consumption of water was the least.

At the location chosen for diverting the water the canyon widens out into a basin. Across the lower or southern portion of this an earth dam was thrown. This dam is 535 ft. long, 92 to 135 ft. wide at the base, 24 ft. at the top, and has a height of 19 to 31 ft. It is curved up the valley in plan to get it onto higher ground. The original creek-bed is near the eastern end. The slopes are 2 to 1 on the upper and 1½ to 1 on the lower side. As no suitable material for puddling could be procured at the site, it is homogeneous throughout. The material is a mixture of sand, clay and gravel, obtained from within the reservoir site. This was well compacted during building, having the advantage also of the rains during the year or more of construction.

The reservoir is oblong in shape, running east and west, and contains an area of 8¼ acres. The depth ranges from 10 to 35 ft.; with an available working depth of 12 ft. With this drawoff depth the reservoir furnishes a supply of 55 cu. ft. per second for 24 hours, independent of the flow of the stream.

At the east end of the dam is an overflow waste-way, 30 ft. wide and 5 ft. below the top of the dam, being cut through the end of a sharp rock ridge. Through this same ridge and just east of the waste-way is a drain tunnel for carrying off the surplus flow of the creek. This tunnel is 180 ft. long and is timbered and planked inside to a section 6½ ft. square. It is through slate and quartzite, and the openings at the ends between the timber and rock are well back-filled with cement concrete.

At the entrance to the tunnel is a penstock for regulating the level of the water in the reservoir. This is 6½ ft. wide in the clear by 26 ft. high and 24 ft. long. The sides are brought up to the same elevation as the waste-way before described, and the front or upper end is provided with two iron gates and with movable flash-boards above them. The sills, posts and caps of the penstock are all 10 × 12-in. timbers; the bottom and sides are of 3 × 16-in. plank, bolted to these. The two cast-iron gates are each 3 × 3 ft., and are moved by screw-stems extending to cross-beams at the top, where they are operated by worm gearing. The gates move in iron guides. The penstock is sunk 7 or 8 ft. into the ground, and is well weighted down by heavy rock piled over the ends of its sills and other special projecting timbers near the bottom. When the reservoir rises above high-water level, the water pours over the sides of the penstock, falling to the bottom to be carried away through the tunnel.

The dam and underground fissures passed considerable seepage water at first, which has been gradually and nearly all shut off by placing additional dirt on the upper side. The water slope has also been rip-rapped with a layer of loose rock.

As the county road up the canyon passed through the reservoir site, it had to be changed to pass around, on the east side and high up the ridge before mentioned. This required much heavy and expensive work. Of the 1,200 ft. of length, 1,040 ft. is hill-side work, called "dugway," and 160 ft. is in a through rock cut, 60 ft. deep in maximum cut and passing through the ridge. The creek is crossed in a new place near the upper end of the new location, by a strong timber bridge on a heavy grade.

Tunnel.

In order to utilize the reservoir site and to take advantage of the "cut-off" across the low divide, already spoken of, to the power house site, it was necessary to tunnel through this divide to draw water from the reservoir. This was accomplished by a tunnel 430 ft. long, driven through the slate and quartzite. This was done by hand-power and by rotary electric drills of Mr. Jones' invention.

The summit of the divide is but 65 ft. above the tunnel. The tunnel section is 7 ft. wide by 7½ ft. high, and timbering was needed for only a short distance at the west or lower end. The grade of the tunnel is 0.2%.

Wooden Stave Pipes.

As it was desired to draw water from the creek as well as the reservoir, a pipe was laid to take water from the creek above the east end of the reservoir and carry it to a common regulating receiver or intake near the lower end of the reservoir.

The receiver of the wood pipe is made from a turbine case built for two different sized wheels, taken from a paper mill. It is 6½ ft. wide by 9½ ft. long and 6 ft. deep, with cast-iron heads and riveted steel sides. The front side was cut away for a diversion of water, being replaced by a screen composed of bars ¼-in. by 1½ ins. deep, ¾-in. mesh, and 48 sq. ft. in size. The intake is set in concrete and cemented at all joints. A cast-iron flange inserted at the back serves for connection with the wood pipe, oakum being used at the junction of ironwork and wood pipe at both ends of the latter. The approach to the intake is paved with shale slabs, and it is set so low that no dam is needed to divert water from the creek into it.

The pipe is laid in the reservoir for most of its length, it being preferable to do this under the conditions than to go around. It is 1,420 ft. long, 50 ins. inside diameter, and is made of Oregon fir staves, banded with steel bands. A circular section consists of 31 staves, each milled from a 2 × 6-in. piece, the thickness reduced to 1 11-16 ins. These are banded every 10 ins. with 9-16-in. round steel bands, upset and threaded at each end instead of one end, as is customary. By this it is claimed that the tightening is made easier and more certain, the drawing up being in a more direct line and with less friction. Cast-iron lugs are used for joining the ends of the bands, being really double lugs. The pipe is anchored down to the bottom of reservoir by loops of the same kind of wire, the end on each side being fastened to a "dead man" buried and weighted with rocks. Part of the pipe is laid on loose rock and part on earth, 100 ft. or more being laid on trestles. The average depth of the water over the pipe is 14 ft.

Receiver and Reservoir Intake.

This structure, being what is called the "valve tower" in most reservoirs, is at the west end of the reservoir. It is 7 ft. 2 ins. diameter, 24 ft. high, of ½-in. steel plates, and was made by altering a digester, also taken from a paper mill. It is set on concrete and is 32 ft. from, and directly opposite, the head of the tunnel. It has three 50-in. openings with flanges for connections to the wood pipe, a steel pipe outlet and the reservoir intake fitting. Over each opening and on the inside of the receiver is placed a simple 50-in. flap valve, moving on hinges and raised and lowered by chains extending to a differential pulley block on top of the receiver. This is suspended from a three-legged angle iron stand surmounted by an iron umbrella for protection against weather. The top and bottom of the digester were of ¾-in. plate and curved, and to level it up on top a floor of cement was put on, encircled by a banded wooden cap.

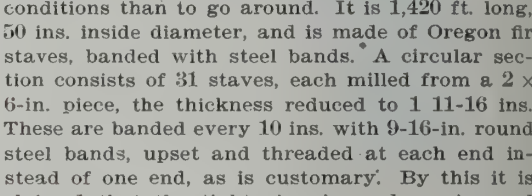

Fig. 8. Cross Section of Reservoir Dam, Big Cottonwood Power Plant.

The reservoir intake, for admitting water directly from the reservoir to the receiver, is enclosed by a heavy wire screen that is expanded to give a much larger area than the opening itself, to insure a full supply of water. The wooden pipe discharges into the receiver and the steel

SALT LAKE CITY, UTAH.

R. M. Jones, Engineer.

pipe draws from it and leads to the power house. The three openings are 12 ft. below high water.

Steel Pipe.

The steel pipe passes through the tunnel and thence down the west slope of the mountain and valley to the power house.

There are 2,300 ft. of the following description:

Length.	Diameter.	Thickness.	Head.
636 ft.	50 ins.	¼-in.	12 to 75 ft.
224 "	50 "	5-16-in.	75 " 150 "
224 "	49 "	⅜-in.	150 " 225 "
224 "	49 "	7-16-in.	225 " 300 "
992 "	49 "	½-in.	300 " 380 "

An ordinary section of pipe is 32 ft. long, being made up complete from four 8-ft. sections before shipment. The pipe is double-riveted, with flange connections and copper gaskets, each of the joints of the 71 sections being made up with 52 × 1¼-in. steel bolts. Each of these gaskets was made by taking No. 4 soft-drawn copper wire and wrapping it in a single layer of five complete turns in the joint between flanges. This was done by winding around a wood template placed on one flange, the wire being then soldered to the flange at intervals and the template removed. The flanges were then brought as closely together as possible with 4-ft. wrenches applied to the bolts, after which the joint was gone around with driving bar and set hammer and "flogged" to flatten the wire still more, this process alternating with tightening of the bolts two or three times till the wire was nearly flat and the joint perfectly water-tight. The gaskets thus made cost about 80 cts. each, while $2.50 to $3 would have been the cost of any of the ordinary gaskets on the market.

Thirty flange connections are on angles, with beveled joints, used on the curves, one horizontal and one vertical, each with a radius of 293 ft., and one compounded of a horizontal and vertical curve, giving a radius of 414 ft., and thereby also providing for expansion. The pipe is covered where deemed necessary, and on its steepest grades has inclined stay-braces of wood, abutting against the flanges and resting against timbers buried in the ground, to prevent its moving down hill. Thirty-two feet at the head of the pipe is submerged in the reservoir, thence the tunnel is entered, the pipe being passed through a concrete bulkhead, well cemented at the joints and placed about 15 ft. within the portals. A footwalk reaches from the cliff above the tunnel entrance to the intake receiver, being supported by four 2½-in. iron pipe columns set on flanges on the steel pipe below, and used both as columns for the bridge and for air valves for the pipe. Just outside the west end of the tunnel another air-pipe rises from the steel pipe. This is 4 ins. diameter, rises 18 ft. high or above high-water in the reservoir, and is open at the top like the others.

Power House.

The power house is located on the north side of the creek, some distance below the "Stairs" and the horse-shoe curve in the creek. The outside dimensions are 34 × 100 ft.; it has two stories, the first 21 ft. in height and the second 11 to 13 ft. in height.

The foundations are of concrete, with a 10 ft. bed under the machines and 2 ft. under the rest of the floor of the house, with cement coverings. The walls are of brick, the framework of steel, the second floor of brick arches and the roof of concrete, both built on I-beams. The structure is absolutely fireproof in every part, and is very substantial. The roof covering is of asphalt and gravel.

Upon the first floor are the water-wheels, the generating aparatus and the switchboards. The second floor has the step-up transformers with their regulating boards or panels, and also living rooms for the employees.

On the south side of the building is the tail-race, a pit built with very heavy concrete walls and bottom. It is 100 ft. long, 7½ ft. wide, 6 ft. deep at the upper end and 9 ft. deep at lower end.

The "header" or receiver is erected in this, being supported by cast-iron columns with large footings resting on the bottom of the pit. This receiver is 100 ft. long, 50 ins. in diameter, and is of ½-in. riveted steel plates, and cast-iron plates with radial braces at the ends. The discharge water passes along the pit, under the receiver, and thence can be discharged back into the creek.

Inside the building is a traveling crane with ten tons capacity, covering the entire area of the first floor of the house.

Water Power Machinery.

This consists of four special double-nozzle Pelton water-wheels, each is 61 ins. in diameter, and will develop 700 HP. with the effective head of 370 ft. obtained. Each wheel is keyed directly on the armature shaft of its generator. Water is supplied to each wheel through a 20-in. pipe tapping the receiver on one side and running horizontally through the wall, then making two 90° curves, one vertically to bring the water up above the floor, and one horizontally to turn the pipe into line with its wheel, lengthwise of the building. The curves have a 4½-ft. radius and are reduced to 16 ins. inside diameter.

Each wheel and its generator rest on one solid base-frame. Each nozzle is 3½ ins. diameter, the straight nozzles are each provided with a gate valve, and each lower nozzle is equipped with a hood regulator, to secure good regulation and economy in water consumption. The wheels run at 300 revolutions per minute, and each carries 20 buckets.

A cast-iron housing is placed over each wheel and the discharge water falls below and passes out through openings in the foundation wall to the tail race. As part of the hydraulic machinery, there is also a regulating equipment for each of the four generators. There are also all pipe connections, valves, gages and other appliances needed for regulation.

Electrical Generators and Equipment.

There are four three-phase generators with 24 poles, each having a capacity of 500 K-W. They generate a 500-volt current with a frequency of 60 cycles per second. Each has three armature bearings, having an extended shaft, and is on the same base-plate as its water-wheel.

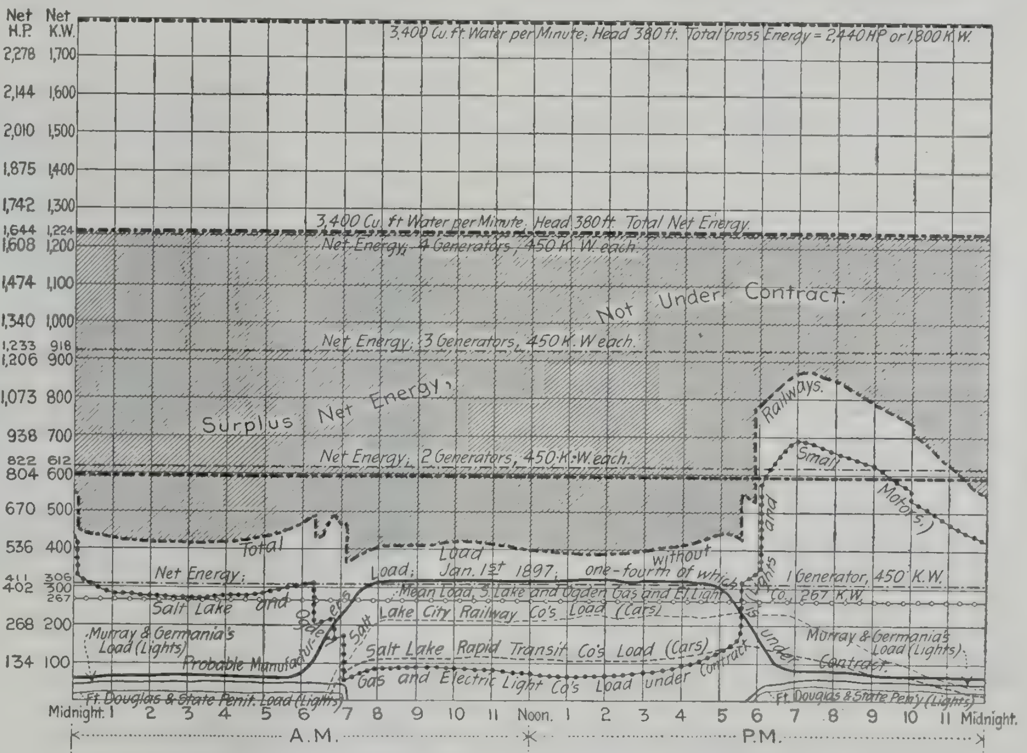

FIG. 9.—DIAGRAM SHOWING AVAILABLE ENERGY, AT "THE STAIRS," OF THE BIG COTTONWOOD POWER CO. AND THAT UNDER CONTRACT AND ESTIMATED FOR, JUNE 1, 1896.

There are two 25 K-W. independent exciting generators, of the Edison bi-polar type. Each generator has capacity sufficient to excite the fields of all the alternators, and is driven from two 13-in. Pelton wheels, direct connected with the armature, and run at a speed of 1,300 revs. Generators and motors are set upon one cast bed plate. On the north side of the machinery room is erected the five-panel station switchboard, with complete controlling and indicating apparatus. There is also a tachometer driven by a synchronous motor.

Up-stairs are six 265-K-W. air-blast transformers, raising the voltage from 550 to 10,500. There is a Sturtevant exhaust fan for cooling the transformers, driven by a 5-HP. induction motor. Over 4,000 lbs. of soft rolled polished copper bars were used in the wiring of the station.

Transmission Line.

As this development of power was made with the primary object of transmitting electrical energy to Salt Lake City, the transmission line is made as direct as the country will allow, it being intended to run branch lines to such places as may demand it.

After leaving the canyon the line runs in a general north by northwest direction, and the total length to the distributing station, on South 3d and State Sts., in the city, is 14 miles.

The poles are of Idaho cedar, and are 40 ft. long and 9 ins. in diameter at the top. Some special ones are 50 and 60 ft. long and 10 ins. in diameter at the top. The poles are placed at an average distance of 120 ft. apart. Each has two cross-arms of spruce, each 4 × 6 ins. by 9 ft. These are fastened with lag bolts and braced on each side. There are six special pattern, double-petticoat, porcelain insulators to each brace, each tested to 40,000 volts. The line conductors consist of 12 wires, four circuits of three wires each. All of the circuits are of No. 2 B. & S. gage soft-drawn, bare copper wire and the total length of the wires amounts to 168 miles.

A telephone line is strung below the transmission wires, mounted on a short cross-arm to each pole. The telephone circuit consists of two No. 12 hard-drawn copper wires transposed between each two consecutive poles for its entire length. A total of 224,000 lbs. of wire was purchased by the company for its various uses.

The chief user of the electrical current furnished at the present time is the Salt Lake & Ogden Gas & Electric Light Co., which is the older and larger light company in Salt Lake City. By a contract to run ten years, from Jan. 1, 1896, the electric light company is supplied with all the current it can use and dispose of for light and power, its right to supply other parties, however, being limited to units of 10 HP. and under, for any one motor, except for elevators, where there is no limit. By the contract the current is bought at 2,200 volts at the sub-station at a stipulated price per K-W. hour, and 2,000,000 units annually is stipulated to be the minimum limit of consumption.

About 3,000,000 units per annum has been the production of the light company by use of coal. The distributing station or sub-station is owned by the light company, which rents it to the power company at a nominal figure. In it are nine 160

K-W. air-blast step-down transformers, reducing the voltage from 10,500 to 2,200, at which it is measured to the light company. There is also a three-panel switchboard, with regulating and other apparatus. A 24-panel Ball lightning arrester is also placed here. The following efficiencies of the different parts of the entire system are claimed by the builders of the machinery:

Water-wheels	80%
Generators	94%
Step-up transformers	97½%
Line transmission	95%
Step-down transformers	97½%

This indicates that a net energy of 68% of the theoretical horse-power at the power house will be delivered at Salt Lake City as electric current.

The load has not yet reached a limit which enables an accurate measurement, but it is thought that all the machines will fulfill the claims of the manufacturers; some tests have shown the efficiency of the Pelton wheels to be 85%. The plant has been in operation since June 2, 1896.

The power company also has the contract, to begin one year from June 15, 1896, for street lighting in Salt Lake City, furnishing 276 arc lights at $102 per light, moon-light schedule. It reserves the right, in its contract with the light company, to supply power to motors in units of over 10 HP., and also has the right to reach such users of large power by wires erected on the light company's poles anywhere within the city limits.

It has already closed contracts with two or three other small users of power. The prospective users with whom no contracts have yet been made, consume at present over 2,000 HP. by use of steam. These include various factories, smelters, etc., in the city and at Sandy and Murray, south of it. For those in constant operation day and night, the power costs at present $90 to $145 per HP. per year. Most of the rest are manufactories, running 8 to 10 hours daily, except Sunday, at a cost of $35 to $75 per HP. per year.

It is stated that by the sale of 2,000 or more HP. to these parties the present income of the power company will be increased to $150,000 or more per annum. It is also figured that the earning capacity of the plant will be $200,000 if the current can be marketed so as to allow the maximum load that can be carried to be used.

A branch line is now nearly completed, called the Murray line. This leaves the main line about midway of its length and extends west on 16th South St. (outside the Salt Lake City limits) to State St., a distance of 3½ miles. Here is located a sub-station, a small brick building containing three 160 K-W. air-blast transformers, wound at a ratio of 10 to 1, and giving a secondary production of 2,200 volts.

From here a line is to be extended north two miles to the "Husler Mill," a 150-bbl. flouring mill. Power will be supplied here through a 30-HP. 220-volt induction motor. From the sub-station is being run a heavy secondary or 2,200-volt line to the village of Murray, one mile to the south. This town will be lighted by the electric current.

Several large smelters and similar works are located here and expect to use the current for lighting, and also for power when the necessary changes can be made. The sub-station at Murray has a capacity for handling 500 K-W. The smelters are run day and night the year around.

The Murray line has one circuit of three wires, the poles being of the same size as for the main line.

Cost, Income, Etc.

The construction cost of the completed system has been $325,100, distributed as follows:

Dam, reservoir and all appurtenances and head works, and 430-ft. tunnel	$56,350
Wooden stave pipe, constructed	8,540
Wooden stave pipe intake	400
Reservoir intake	1,760
Steel pipe and connections	41,250
Power house, foundations and tail-race	14,800
Travelling crane	1,400
Water wheels, pipe connections and regulators	13,175
Electrical machinery and equipment	96,200
Transmission line to Salt Lake City	58,100
Engineering superintendence, office expense, etc.	35,125
Total	$325,100

The annual operating expenses of the system when working at full capacity, including expenses of office, management and taxes, is put at $18,000, which, from the detailed figures it is based on, seems a liberal allowance.

The company has a 25-year franchise for the transmission and distribution of electrical energy from Big Cottonwood canyon to all places in Salt Lake county, and one for the same time for distributing light and power through all the streets and public places of Salt Lake City.

The following figures show the cost of the installation per HP. on different assumptions:

1. Actual cost of construction $325,100
   Actual minimum water power, 2,400 HP., or $135.50 per HP.
2. Construction cost as before 325,100
   Actual station capacity and usual power, 3,000 HP., or $108.25 per HP.
3. Net value the "Stairs" division 400,100
   Usual available power, 3,000 HP., or $133.60 per HP.

The net value is obtained by adding $75,000 to the construction cost, being $25 per HP. for water-right.

All work on the construction of this plant was by day labor, and no expense was spared to make all parts the most secure and substantial possible.

The steel pipe was furnished by Fraser & Chalmers, of Chicago; the wood pipe was built by the power company itself; the water wheels were furnished by the Pelton Water-Wheel Co., of New York and San Francisco; the wire by the John A. Roebling Sons Co., of Trenton, N. J.; the electrical generators and all equipments by the General Electric Co., and the regulating apparatus and local machine and foundry work by Silver Bros., of Salt Lake City. All parts of the system have worked very smoothly. It was stated that a few days after starting up, the greatest flood in 35 years poured through the canyon, with no damage whatever to any of the works.

Besides the completed "Stairs" division, the company has two other water power rights on the same creek, which it proposes to develop as follows:

I. Granite Mills Division.—This division begins nearly one mile within the canyon and extends to the mouth. It is principally based on the water rights and property once belonging to the Granite Paper Mills Co. This company had a paper mill at the mouth of the canyon, with water power machinery. The power development consisted of an open ditch with 8-ft. bottom and 5-ft. depth, leading water from the creek for 3,300 ft. along the hill-side or north side of the canyon. Here the supply to the mill consisted of a flume 8 × 4½ × 130 ft., leading out from the hill to a penstock 8 × 8 × 24 ft., from the bottom of which a single-riveted steel pipe of 48 to 38 ins. diameter and 460 ft. long led down to a Leffel 26½-in. horizontal turbine in the mill, giving a working head of 132 ft.

The mill burned down in 1892, leaving the walls standing, and the entire property has since come into possession of the water power company. Five brick dwelling houses and 200 acres of patented land, with irrigation water rights, are also included, the improvements all being situated thereon. A side-hill grade for wood pipe had been started, tapping the creek 1,200 ft. higher up. By carrying water to the contemplated station site, 1,000 ft. below the old mill, a static head of 357 ft. will be obtained, giving, with minimum supply from the creek of 3,400 cu. ft. per min., 2,300 HP.

II. Mill "B" and Mineral Forks Division.—This division begins at the head of the "Stairs" division and extends up the creek for a distance of over 2½ miles, with a fall of nearly 900 ft. The improvements consist of an old saw-mill and its intervening water rights and some 2,800 lin. ft. of side-hill grade for new construction.

The "Stairs" development and installation of water power, according to modern methods, was the pioneer of such projects in Utah, and the example set thereby has largely stimulated interest and called attention to other possibilities. The many streams draining the west slope of the Wasatch Range afford some ideal advantages for the production of water power, which have been fully realized and grasped by other projectors.

The officers of the Big Cottonwood Power Co. are: Col. J. W. Donnellan, President; W. H. Rowe, Vice-President; Geo. M. Cannon, Secretary; R. M. Jones, Engineer and Manager; J. W. Sumnerhayes, Member Executive Committee, all of whom have worked in unison to carry the construction to successful completion. The engineering work in all departments was done by Mr. R. M. Jones.

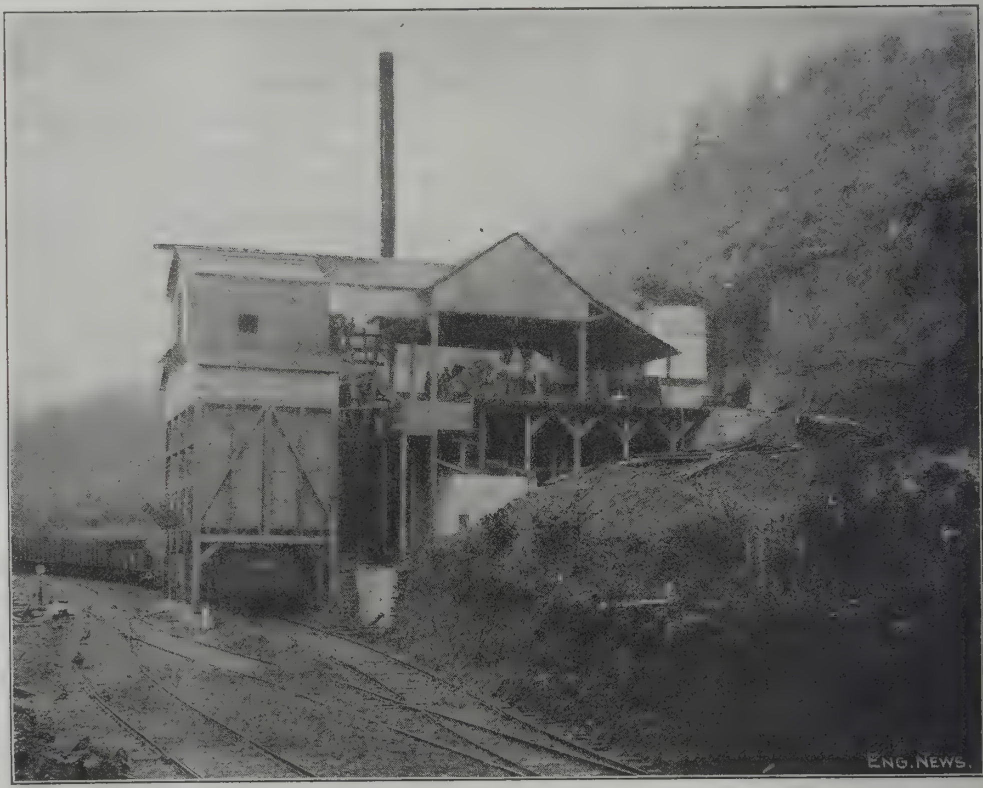

FIG. 1.—ROCK CRUSHING PLANT OF THE NEW ENGLAND TRAP ROCK CO., WESTFIELD, MASS.

A MODERN STONE-CRUSHING PLANT.

A very large stone crushing plant has recently been erected by the New England Trap Rock Co., at its quarries near Westfield, Mass., on the line of the New York, New Haven & Hartford R. R. The plant (Fig. 1) is situated on a level with the quarry, which is not more than 100 ft. distant. running along the side of the mountain. The rock is excavated by means of drills and dynamite and is broken up and loaded into end dump cars. These deliver it to the crushers, of which there are three, all of them of the "Farrel" (Blake pattern), 36 × 18 ins., set on substantial concrete foundations (Fig. 2). The total weight of each crusher is about 50,000 lbs. The capacity of each varies from 300 to 800 tons in ten hours, according to the size to which the pieces are broken, The driving pulleys are run at about 275 revs. per minute and about 40 HP. is required to operate each crusher. The crushed rock as it leaves the machine slides down a chute directly into steel elevator buckets which carry it up and discharge it into two 48-in. steel sizing screens. Each of these screens is about 18 ft. long and is composed of three sections, each with different perforations, which sort the broken stone into three separate bins. The screens are inclined ¾-in. to the foot. Pieces which are too large to pass any section of the screen are returned by a conveyor to the crushers. Doors similar to those used in coaling chutes permit the crushed stone to be drawn off either from the side or from the bottom of the bins. The crushers and all other machinery are driven by a 20 × 24-in. horizontal engine, especially designed for this work. The engine is coupled direct to a jack shaft to which the crushers are connected by leather belts. Steam is supplied by horizontal tubular boilers, which also supply steam to the drills in the quarry. The entire work has been done in the very best manner throughout, with the intention of making it a first-class plant in every respect. The plant has a capacity of 1,000 tons per day and cost complete about $25,000.

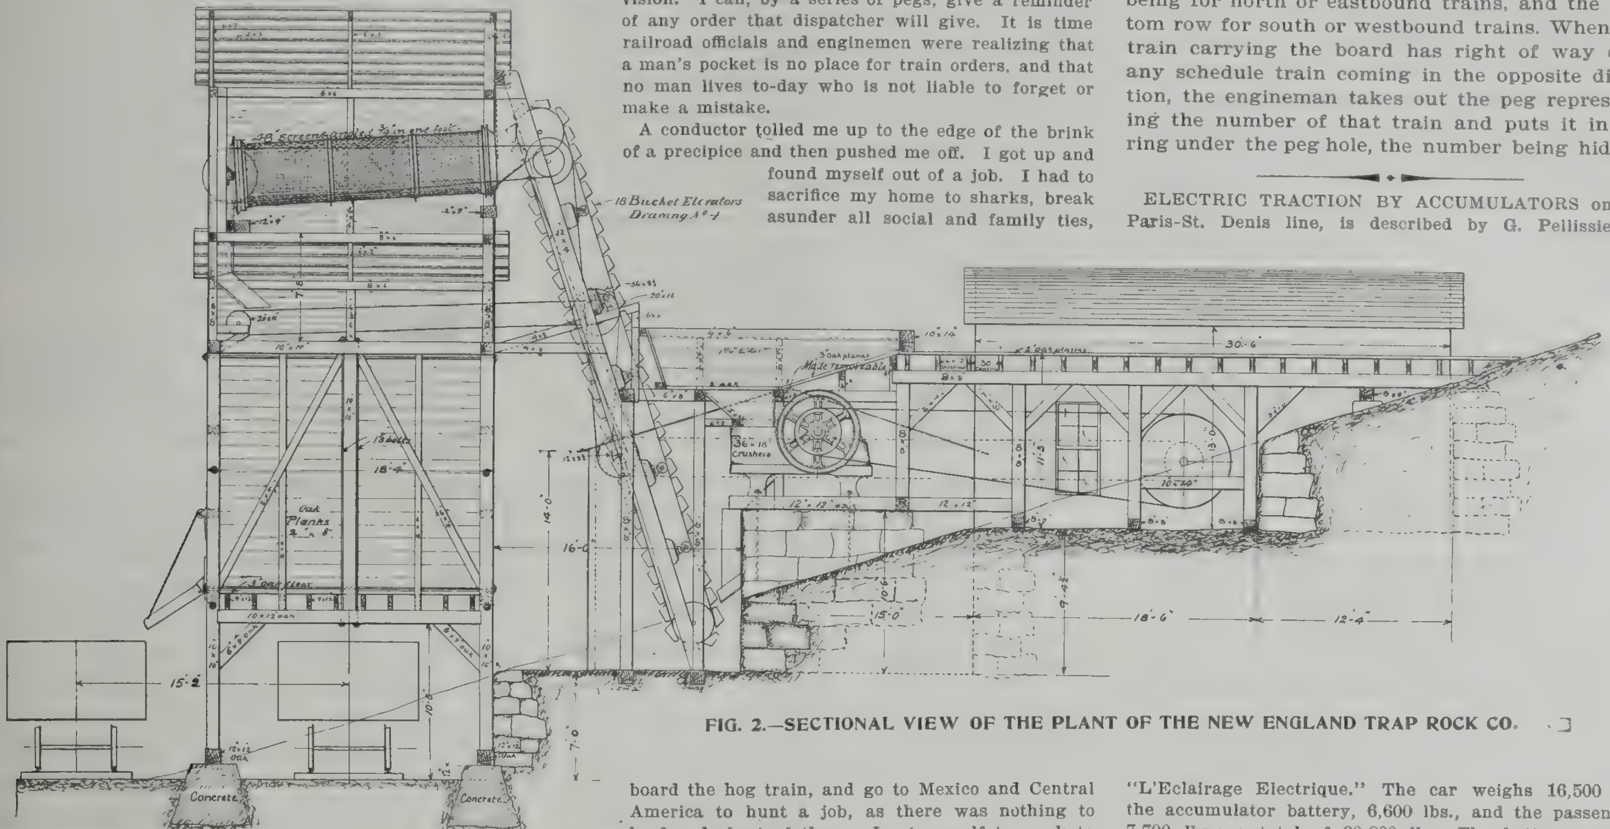

FIG. 2.—SECTIONAL VIEW OF THE PLANT OF THE NEW ENGLAND TRAP ROCK CO.

The officers of the New England Trap Rock Co. are: President, N. A. Harwood, Chester, Mass.; Treasurer, E. A. Carter, Springfield, Mass.; Manager, J. A. Talmadge, Westfield, Mass.

The entire plant, including the engine, crushers, bins, etc., was designed and erected for the New England Trap Rock Co. by Mr. Earle C. Bacon, M. Am. Soc. M. E., Havemeyer Building, New York city. We are indebted to Mr. Bacon for the matter from which this article and our illustrations are prepared.

◆

TRAIN ORDER BOARD FOR LOCOMOTIVE CABS.

The forgetting of train orders by the engineman has always been a fruitful source of railway collisions, and though steps have been taken to check this by impressing the order upon the man's mind by directing him to read it aloud to his fireman, forgetfulness is still a too frequent cause of accidents. On some roads the train order is placed in a frame in the cab, where the men can see it, but a still better plan is a graphic reminder in the shape of a train order board, with pegs marking the meeting points or stations. This device is shown in the accompanying cut, reproduced from a photograph sent us by the inventor, Mr. A. W. Jennings, of McComb, Miss., who describes it as follows in a letter to "Locomotive Engineering:"

> I send you photographs of a device which I have been granted a patent on. One is an order file for the use of locomotive engineers; the other a board containing the names, in cast aluminum letters, of all stations on the division. I can, by a series of pegs, give a reminder of any order that dispatcher will give. It is time railroad officials and enginemen were realizing that a man's pocket is no place for train orders, and that no man lives to-day who is not liable to forget or make a mistake.
>
> A conductor tolled me up to the edge of the brink of a precipice and then pushed me off. I got up and found myself out of a job. I had to sacrifice my home to sharks, break asunder all social and family ties, board the hog train, and go to Mexico and Central America to hunt a job, as there was nothing to be found short of there. I set myself to work to remedy the evil before I started, and give those I left behind with a job some protection against losing it.
>
> On the board I use red peg to denote meeting point between two extras—the numbers of regular trains opposite the station where they are to meet. A white peg for the terminus of an extra. A peg with red cross on black background for wait order. The two rows of numbers at bottom of board are schedule trains. The numbers of trains having right of track over train carrying board only will be left in sight.

A Train Order Board for Locomotive Cabs.

In a letter to us respecting this device, Mr. Jennings says that his file is 8 × 12 ins., and his order board is 6 × 18 ins., and costs about $3. The train carrying the board shown has orders to meet train No. 55 at Beauregard, therefore the peg is stuck opposite the name of this station or meeting point. The two bottom rows of pegs represent the schedule trains on the division, the top row being for north or eastbound trains, and the bottom row for south or westbound trains. When the train carrying the board has right of way over any schedule train coming in the opposite direction, the engineman takes out the peg representing the number of that train and puts it in the ring under the peg hole, the number being hidden.

◆

ELECTRIC TRACTION BY ACCUMULATORS on the Paris-St. Denis line, is described by G. Pellissier in "L'Eclairage Electrique." The car weighs 16,500 lbs.; the accumulator battery, 6,600 lbs., and the passengers, 7,700 lbs.; a total of 30,800 lbs. The battery contains 108 cells of 11 plates each, arranged in 12 wooden boxes, 6 on each side of the car. These boxes can be withdrawn and replaced by charged boxes in 6 minutes. When fully charged the car can run 37 miles on the Broca type of rail, and twice that distance on a T-rail. The cost per car-mile of operating the car is set down at 14.48 cts., as compared with 9.24 cts. per car-mile for overhead electric traction in Paris. This cost is divided as follows: Handling accumulators, 1.84 cts.; maintenance of same, 3.08 cts.; maintenance of motors and trucks, 1.56 cts.; motive power, 5.54 cts.; wages and superintendence, 2.46 cts. With a new accumulator system lately tried the cost is stated to be only 10.46 cts. per car-mile.

◆

A GAS EXPOSITION, the first of the kind in this country, is to be held in Madison Square Garden, New York, beginning Jan. 25, 1897, under the auspices of the Gas Industries Company. The full program has not yet been published but the list of officers and directors of the managing company include many well-known men whose names should be a guarantee of success. Among these men are Hon. Calvin S. Brice, New York; Gen. Asa A. Bushnell, of Ohio; Thomas Dolan, of Philadelphia; Gen. James H. Jourdan, of Brooklyn; Dr. Henry Morton, of the Stevens Institute; Prof. T. C. Mendenhall, late Superintendent U. S. Coast Survey; Thomas F. Rowland, Brooklyn; Frank Tilford, New York; and Walter Wood, of Philadelphia. Space is to be allotted to intending exhibitors on Oct. 15.

◆

THE PHILADELPHIA & READING R. R. was sold at auction at Philadelphia, Pa., Sept. 23, and was bid in by Mr. C. H. Coster, representing J. P. Morgan & Co., for $4,500,000, this including the property of the railway company and the coal and iron company. Notice was given on behalf of the city of Philadelphia that the contract entered into between the city and the railway for the construction of a subway would have to be carried out under the new order of things, and that the city of Philadelphia, as trustee under the will of Stephen Girard, would not consent to the immediate transfer of the coal lands which have been leased to the railway company. Under the reorganization the annual charges will be lessened $717,900. The present fixed charges of the railway and coal and iron companies aggregate $10,035,073, and under the reorganization they will be $9,317,173.

◆

THROUGH TRAINS TO TREMONT over the New York elevated railways have now been put in service, the trains running from the Battery to 177th St. Formerly the trains only ran to the Harlem River and passengers had to change cars, while now the trains run through and only a single fare of 5 cts. is charged for the run of 12½ miles.

WHITEHEAD TORPEDOES are being made by the E. W. Bliss Co., of Brooklyn, and the first five will be ready for testing on Nov. 1. In all 100 18-in. twin-screw torpedoes were contracted for, the price being $315,000. These torpedoes are 18 ft. long and carry 250 lbs. of dynamite. The motive power is compressed air stored within the shell and the extreme range is one mile. The Bliss Company has already made 250 torpedoes for the government.

A 12-IN. BROWN SEGMENTAL WIRE-WOUND GUN is recommended by the Ordnance and Fortification Board and an appropriation of $33,000 is made from the experimental fund for this purpose. A gun of this type was tested two years ago and 200 rounds were fired from it at remarkably high pressures without developing any weak points. The Board believes that this test warrants further experiments with a larger caliber and make their recommendations with the approval of Secretary of War Lamont. This gun was fully described in our issue of Nov. 24, 1892.

A HUGE CAST-STEEL PROPELLER, said to be the largest ever made in this country, was recently cast at Chester, Pa., for the new iron steamship "John Englis." It measures 16 ft. diameter from tip to tip of blade, and the hub is 26 ins. diameter. The thickness of the metal at the hub is 6 ins. The casting weighed 15,000 lbs. The steamship "John Englis" is 312 ft. long, 46 ft. beam, with a gross tonnage of 4,000 tons, and is intended to run between New York and Portland, Me. The engines are triple-expansion, of 4,000 HP. and they will drive the propeller at 90 revolutions per minute.

THE FIRST HEAT OF BESSEMER STEEL in the new works of the Troy Steel Co., on Breaker Island, near Troy, N. Y., was made on Sept. 15.

A TOREDO-PROOF PAINT, invented by Thos. J. Childerson, of Pensacola, Fla., has been tested by a naval commission. In March last four pieces of solid heart pine wood were sunk at the navy yard there. One piece was unpainted and the others had one, two and three coats of the paint respectively. The pieces were raised and examined lately. The unpainted piece was honeycombed by the toredo and fell to pieces. The other three were not touched by the insects and were perfectly dry in the interior. The commission reported the paint as a success. We take the above from Washington press dispatches. It is certainly important if true.

THE BOSTON PNEUMATIC TRANSIT CO. has received permission from the aldermen of that city to lay and operate a series of underground conduits for the transmission of mail matter, messages, packages and other articles. A similar order of the board was vetoed last year by Mayor Curtis, and a bill was later passed by the legislature removing the legal obstructions to its passage by the board of aldermen. The mayor now has ten days in which to consider whether he shall approve or veto the franchise.

RESOLUTIONS GRANTING ELECTRIC LIGHT, telephone and subway franchises have been vetoed by Mayor McGuire, of Syracuse, N. Y. The grantees are said to be practically identical in each case. The principal ground for the veto was that the franchises provide for no compensation to the city.

A STONE CRUSHER DRIVEN BY AN ELECTRIC motor is in successful operation at Peterboro, Canada, the current being furnished from the station of the Peterboro Light & Power Co., a mile distant. The motor is of 65 HP. capacity, and it runs the crusher readily when the latter is jammed full of the hardest stones obtainable.

THE WATER-POWER PLANT AT OGDEN, UTAH, of the Pioneer Electric Power Co. was described in detail in our issue of Nov. 8, 1894, by our special contributor, Mr. W. P. Hardesty, C. E. This extensive enterprise involves the development of about 10,000 HP. and the transmission by electricity of a considerable portion at a potential of 15,000 volts to Salt Lake City, a distance of 36 miles. The work has now proceeded so far that the company has awarded the contract to the General Electric Co. for the electrical machinery. The reservoir, dam and pipe line were described in our former article. In the power-house will be placed five Knight water-wheels made by the Risdon Iron & Locomotive Works, of San Francisco, running at 300 revolutions per minute and controlled by Knight automatic governors. Upon each water-wheel shaft will be mounted a 24-pole, three-phase generator wound for 2,300 volts and with a periodicity of 60 cycles per second. Two independent 100 K-W. exciter dynamos, each driven by its own water-wheel, will be placed, and the current from either will be sufficient to charge the fields of all the large machines in the station.

The current from the generators will be carried by lead-covered cables laid in ducts between the generator foundations and the wall of the building to the generator switchboards at one end of the power-house. The boards will have blue Vermont marble panels, and will be completely equipped with all the necessary controlling and regulating instruments and apparatus. Tachometers on the switchboard, operated by synchronous motors electrically connected to the generators, will indicate the speed of the machines.

The step-up transformers and the 2,000 and 15,000 volt feeder panels will be placed in a gallery erected over the generator switchboard. The transformers, nine in number, each of 250 K-W. capacity, will raise the generator potential from 2,300 volts to 15,000 volts, at which pressure 2,000 HP. will be transmitted to Salt Lake City. The local distribution of the balance at Ogden will be made at 2,300 volts.

The transmitted current will pass over six No. 1 wires strung on insulators of a special porcelain, developed by the General Electric Co. to withstand high potentials, to nine 250 K-W. step-down transformers at Salt Lake City, which will deliver it at 2,300 volts for distribution.

The transmission line and transformers will be arranged to allow of the use of a potential of 25,000 volts. This will permit of the efficient transmission of current to the mining regions of Mercur and other camps 30 to 35 miles beyond Salt Lake City. All lines will be protected by the latest types of General Electric lightning arresters.

To construct the iron and wooden pipes bringing the water to the wheels, motors aggregating 100 HP. are set up in the shops of Rhodes Bros., in Ogden, to supply the extra power required for the work.

Salt Lake City, with the completion of the Pioneer plant, will receive power from two of the most important electrical transmission installations ever undertaken. That transmitting the power from the Big Cottonwood Canyon has only recently been completed, that of the Pioneer Co. will probably be inaugurated about Nov. 1 of this year.

POTASSIUM CHLORATE is now being made at Niagara Falls by the Chemical Construction Co. The process is that patented by Henry Blumenberg, Jr., and is based upon the use of an electrical current in connection with a solution of potassium chloride. Power is obtained from the Niagara Falls Power Co., and the product claimed is one ton per day of chlorate of potash, without waste and at very low cost. There are two other electrical processes for this manufacture in use; that of Gall & Monthauer, of France, and Franchot & Gibbs, of Buckingham, Canada; but this one is said to be the first installed in the United States.

THE ELECTRIC RAILWAY proposed to be built along a boulevard between Baltimore and Washington may be abandoned, the construction company (Baltimore & Catonville Construction Co.) having been put in the hands of receivers. It has been stated by the Columbia & Maryland Ry. Co., however, that the work of building the road will be resumed in about two weeks. It is the intention to complete the Baltimore division to Ellicott City as soon as practicable. Most of the work on this division is finished. Construction on the Washington division will also be started. It is said that funds for carrying on the work will probably be obtained by an issue of receivers' certificates.

CIVIL SERVICE EXAMINATIONS will be held in Brooklyn, N. Y., on Oct. 5, for various positions, including sanitary inspectors, chainman, superintendent of sewer and water pumping station, and also inspectors of plumbing, elevators, buildings, gas and electric work, docks, grading and paving, sewer connections, etc. Mr. E. B. Lent is secretary of the Civil Service Commission, with office in the City Hall.

BOOK REVIEWS.

POOR'S MANUAL of the Railroads of the United States, with an Appendix containing a full analysis of the debts of the United States, the several States, Municipalities, etc. Also statements of Street Railway and Traction Companies, Industrial Corporations, etc. H. V. & H. W. Poor. Twenty-ninth annual number, 1896. New York, 44 Broad St. 8vo.; cloth; pp. 1,670. $7.50.

In our issue of Sept. 3 we gave a brief review of the railway situation in the United States for 1895, as obtained from the advance sheets of the Manual. The work now published for issue contains 258 pages more of matter than the edition of 1895, and embraces statements from 4,399 corporations, aggregating a capitalization of $16,475,000,000. Included in this list are 2,040 railway corporations, 1,208 street railway companies, 143 industrial corporations, and a list of the debts of 1,008 states, counties, cities, towns, etc. This simple statement of the volume of contents, coupled with the care and labor bestowed upon the collection and compilation of this information, is sufficient in itself to indicate the value of the publication.

THE MINERAL INDUSTRY, its statistics, technology and trade in the United States and other countries to the end of 1895, Vol. IV. Edited by Richard P. Rothwell, Editor of the "Engineering and Mining Journal," Past-president American Institute of Mining Engineers, Member American Society of Civil Engineers, Fellow Royal Statistical Society, etc. Statistical Supplement to the "Engineering and Mining Journal." New York and London. Scientific Publishing Company. 8vo.; 849 pp. $5.00.

This fourth issue of what is undoubtedly the most thorough and exhaustive publication of this character anywhere exceeds in value even its predecessors. It is impossible to enter here into a review of the contents of these hundreds of pages, and the general scope can only be indicated. The editor, in addition to giving the statistics of quantity and value of product for seventy-odd separate items, treats of each separately, and in almost every case this supplemental material forms a technical treatise upon the methods of treatment, according to the latest discoveries, the mining, tests, prices and general status of the industry discussed. In the preparation of this matter the editor has been assisted by many of the ablest investigators in the development of mineral industries in Europe and America, and some of these articles are in themselves very exhaustive and especially valuable for the figures and information given as to processes and general progress. The subject matter is arranged alphabetically by item and by country, and an excellent index enables the user to readily find what he wants.

PRACTICAL TUNNELLING.—By Fred'k Walter Simms, F. G. S., M. Inst. C. E. Fourth edition, revised and greatly extended, with additional chapters illustrating recent practice by D. Kinnear Clark, M. Inst. C. E., M. Inst. Mech. E., author of "Railway Machinery," "The Steam Engine," "The Mechanical Engineer's Pocket-Book," etc. New York: D. Van Nostrand Co. 1896. Large 8vo.; pp. 548, with 36 plates and other illustrations. $12.

It is almost to be regretted that Mr. Clark issued this work as a revised and extended edition of Simm's Tunnelling, last published 18 years ago; for the 188 pages devoted to the work of Mr. Simm's are now only valuable as a matter of history. In the "Additional Chapters," however, Mr. Clark deals with the more recent and modern practice of tunnelling, as exemplified in the Mt. Cenis, St. Gothard and Totley tunnels, in the tunnels for the Glasgow and Liverpool water-works, the proposed Simplon, and the tunnels at Niagara Falls and under the St. Clair River, Hudson River and the River Thames. In each of these cases the descriptive matter is full and the sections, processes and the drilling machinery are well illustrated. The ventilation of tunnels, especially long tunnels, is an engineering problem so complicated by controlling local conditions that no general rules can be laid down for this purpose. Mr. Clark, however, devotes considerable space to this important subject, and gives examples of various attempts made to get rid of foul air and details the results of such experiments for a number of prominent tunnels. Tunnel practice in America is scarcely touched upon; the exception being the tunnels under the Hudson and the St. Clair rivers, and the Niagara Falls power tunnel. Mr. Clark's work is valuable, however, in bringing together in one volume much scattered information relating to European tunnel work; and while this descriptive matter is made as concise and brief as possible, and useful details are thus omitted, the work as a whole is to be commended.

WATER SUPPLY.—(Considered Principally from a Sanitary Standpoint). By William P. Mason, Professor of Chemistry, Rensselaer Polytechnic Institute. New York: John Wiley & Sons. London: Chapman & Hall. 8vo.; cloth; pp. 504; illustrations and tables; $5.

This book occupies, to a considerable extent, a middle ground between Fanning's "Water Supply Engineering" and Hazen's "Filtration of Public Water Supplies," without infringing upon the territory of either. It resembles in its general plan Nichols' "Water Supply, Considered Mainly from a Chemical and Sanitary Standpoint," but supersedes it, owing to the advances made in the subject since Professor Nichols' work appeared.

The volume opens, practically, with a long and valuable chapter on "Drinking Water and Disease," a subject to which the author has given much attention. A portion of this chapter was printed in Engineering News of June 4, 1896, under the title, "Does Pure Water Pay?" Next comes a chapter on "Artificial Purification of Water," which is principally devoted to a general description of slow sand filtration, and rapid sand, or mechanical, filtration. Natural purification of water is then discussed, the principal sub-heads here being: "Direct Oxidation," "Sedimentation," "The Purifying Action of Sunlight," "Self-purification of Streams," and "Seasonal Variation in Purity of Streams."

After having discussed these subjects, the various sources, or classes of sources, of water supply are taken up in four chapters, these chapters being preceded by one on "Rain, Ice and Snow."

The principles underlying the chemical and bacterial examination of water, together with the methods employed, are treated in two chapters, and another chapter is devoted to consumption of water per inhabitant, a subject having a very important bearing on the sanitary phases of water-supply.

The concluding chapter reviews in an able manner the present understanding of the action of water on metals, and includes some remarks on pipe preservatives. A number of appendices present, among other things, some tables of analyses of city water supplies, statistics of typhoid death rates in American and foreign cities.

Altogether the book promises to be a useful one, while its general make-up is pleasing.

ENGINEERING NEWS
AND
AMERICAN RAILWAY JOURNAL.

Vol. XXXVI., No 15.

TABLE OF CONTENTS.

ENGINEERING NEWS OF THE WEEK........225, 240
- The Park Row Building, 30 Stories High, in New York City (with inset, illustrated).............. 226
- The Present Status of the Distribution and Transmission of Electric Energy..................229, 235
- Garbage Utilization at Cincinnati and New Orleans (illustrated)........................... 236
- The Interstate Commerce Commission's Statistics of the Railways of the United States for the Year Ending June 30, 1896.......................... 238
- A New Water Meter (illustrated)................ 240

EDITORIAL NOTES...................... 232
- Increase in Exports of American Manufactures—The Separation of Ashes and Garbage—Steel Frame Buildings as Consumers of Iron and Steel—The Stability of Steel Frame Buildings.

EDITORIAL.
- The Cheapest Electric Lighting Plant in the World (illustrated).............................. 232

LETTERS TO THE EDITOR...................... 235
- Railway Construction in Japan—The Conversion of Silver into Gold—Nicaragua Canal and Earthwork Slopes in the Tropics.

THE CHICAGO MAIN DRAINAGE CANAL is discussed as follows by President Eckhart in his annual report: Of the work of excavation, 90% is now completed; but the recent pollution of the lake water by sewage demands that immediate steps be taken to secure the full benefit of the sanitary district in the near future. This means the diversion of sewage from the lake, by the united action of the city authorities and the trustees of the sanitary district. Nearly nine-tenths of the present sewage outflow is already discharged into the Chicago River and its branches; and the construction of intercepting sewers by the city will bring the remaining sewage to this channel. The completion of the main channel and the admission of water from the lake, says Mr. Eckhart, will remove the present source of pollution from the lake and restore sanitary conditions in Chicago. The engineering department reports upon the main drainage canal, as follows:

Total amount of contracts	$19,261,619.62
Total amount earned	17,119,942.38
Total amount to be earned	$2,141,677.24
Total reserved percentage and unpaid vouchers	2,231,652.32
Total required to complete existing contracts	$4,373,329.56

Amount earned, 89.03 per cent.

A special committee of the trustees has been appointed to confer with the city authorities concerning the speedy utilization of the drainage canal.

◆

THE WATER POWER AND ELECTRIC TRANSMISSION plant at Fresno, Cal., described in our issue of July 2, is of special interest on account of the great head of the water and the distance which the power is transmitted. The water is carried to the reservoir by 7 miles of canal and flume, and from the reservoir extends the pipe line, 4,020 ft. long, with a total head of 1,400 ft. The pipe is of steel, coated with asphalt, and is laid partly with the Converse screw sleeve joints and partly with flange joints. The cast-iron flanges are shrunk on and beaded to the pipe, reinforced by ¾-in. rivets through flange and pipe between each bolt hole. One flange is recessed and the other has a corresponding annular projection, a 3-16-in. rubber gasket being placed between the faces. The flanges are drawn together by 16 bolts 1 in. diameter, 10¼ ins. long. The pipe was supplied by Dunham, Kerrigan & Hayden, of San Francisco, and the pipe line was made up as follows:

960 ft. of 24-in, riveted No. 12 steel.
860 ft. of 24-in. riveted ¼-in. steel.
400 ft. of 20-in. lap-welded 5-16-in. steel (Converse joints).
800 ft. of 20-in. lap-welded 5-16-in. steel (cast-iron flange joints).
1,000 ft. of 20-in. lap-welded ⅜-in. steel (cast-iron flange joints).

The 5-16-in. pipe was tested to 600 lbs. pressure, and the ⅜-in. pipe to 1,000 lbs. pressure. Air inlet valves of ample area are provided to prevent a repetition of the collapse due to a sudden emptying of the pipe. The pipe ends in a jet driving the Pelton water wheels. The current is carried over a transmission line wire for a distance of 35 miles, and 75% of its power is delivered at the switchboard.

◆

BIDS FOR THE REMOVAL AND DISPOSAL OF THE garbage of Brooklyn were received Oct. 5 from five different parties, as given in detail in our Construction News Supplement. The lowest bid was from the Brooklyn Sanitary Co., which proposes to use the Arnold system of utilization, now employed to treat a large part of the garbage of Philadelphia and soon to be put in use for the treatment of all the garbage of New York. This company made two offers, one for a plant located within the city and another for a plant on Barren Island, where the plant for New York is now being built. The next lowest bid was from E. J. McKeever & Co., for the Brownlee system of garbage cremation. The three offers named were as follows:

	Brooklyn Sanitary Co., for plant.		E. J. McKeever & Bro.
Year.	In City.	On Barren Island.	
First	$90,000	$113,000	$144,000
Second	91,000	117,000	144,000
Third	92,000	120,000	144,000
Fourth	93,000	125,000	144,000
Fifth	94,000	130,000	144,000

◆

WATER POLLUTION FROM SEWAGE has been worse in Chicago this year than ever before, according to reports from the Health Commissioner of that city, and corresponding with this pollution the death rate from zymotic diseases has increased so much as to presage a repetition of the typhoid fever epidemic of 1890-92. For the first nine months of 1896, the number of fatalities from typhoid fever has been 559, an increase of 71% over that for the same period of 1895, and nearly the rate per 10,000 population attained in 1889, just preceding the epidemic noted. The deaths from typhoid thus far in 1896 are 3.17% of the total deaths from all causes. In 1889 the corresponding figures were 2.67%. As noted in the last issue of Engineering News, these conditions have aroused the city officials to exert themselves to find some remedy, and at a recent meeting the special committee on water supply of the city council authorized the mayor to appoint a commission of three engineers to suggest plans for a complete system of intercepting sewers designed to receive the sewage now flowing directly into Lake Michigan and turn it into the Chicago River, whence the drainage canal can receive it. At present, 29 sewers, taking the sewage of some 400,000 people, discharge directly into the lake, 17 on the north side of the Chicago River and the remainder on the south side. Fully 90% of the sewage of the city now enters the lake through the Chicago River, and all this will be diverted through the drainage canal when that channel is completed. The only thing that will prevent the canal taking all the sewage is the flow of the 29 sewers mentioned above directly into the lake, and this the intercepting sewers, if built, will remedy. About 90% of the work on the drainage canal from Bridgeport to Lockport, 28 miles, is now completed, and an official statement from the trustees of the sanitary district asserts that the remaining work necessary to furnish the flow of 300,000 cu. ft. per minute will be finished in 1897 or early in 1898.

◆

ELECTRICITY ON THE MANHATTAN ELEVATED in New York city was given a practical trial, Oct. 5, the experiment being made on the 34th St. branch, between the Long Island Ferry and 3d Ave. A third rail laid on the outside of and 10 ins. higher than the regular rails carries the current. Contact is made by means of two sliding steel shoes. The motor car carries, when fully equipped, a storage battery of 256 cells which may be used in case of blockade or failure of current in the third rail, and which serves to keep the load on the line and on the station fairly uniform. The battery alone, it is said, will operate a train for 19 miles at a speed of 35 miles per hour. The motor car is 18 ft. long and slopes from a height of 8 ft. in the center to 3 ft. at the ends. The electric current is also used to light the cars, which is a new departure on the New York elevated lines. The locomotive has two General Electric motors of 125 HP., and weighs 10 tons.

◆

CAR PAINTING BY COMPRESSED AIR is being tried on the Pittsburg & Lake Erie R. R. The yard is well supplied with air pipes, and the barrel of specially prepared paint is mounted on a hand truck so that it can be moved to any part of the yard. The air line consists of 100 ft. of 1-in. heavy hose; the paint suction hose of 50 ft. of ½-in. heavy hose. The barrel is equipped with a float of pine wood with 4-in. hole in the center. Over the hole is a small hose-bearing tower, used as a support and hose regulator, insuring a uniform feed of paint. This device is light in weight, and can be readily carried to top of a box car for spraying the roof. The time for carefully spraying a box car is 30 minutes. To employ a man to follow with a long-handled 8-in. whitewash brush, 30 minutes additional, making labor cost one hour per box car, each coat. To coat a coal car of 60,000 lbs. capacity takes 20 minutes for each coat, including the time of two men. This road is also using a device for spraying on paint for the lettering, which, for covering uniformly, is considered a decided improvement over the stencil brushes, and will lead to a great saving in the wear and tear of stencil plates.

◆

A FOLDING CAR STEP, set below the bottom fixed step, is being tried on some cars of the Gulf, Colorado & Santa Fe Ry. Its purpose is to facilitate entrance to and exit from the car, and it is expected to be more convenient than the stools or boxes carried by the car porters. A lower fixed step cannot be used, as it would be liable to be struck by platforms, etc. This folding step was designed by Mr. F. W. Farrell, Master Car Builder, at Galveston, Tex.

◆

THE ELECTRIC MOTOR CARS for the Brooklyn Bridge cable railway are now being delivered. They are 45-ft. cars, weighing 28 tons, or 36 tons with the four 100-HP. electric motors and equipment, and closely resemble the present cars. There will be one motor car to each train and it will be used to switch the train from the incoming to the outgoing track, thus dispensing with the present shuttle movement of the steam locomotive which pushes the trains out from the station to the point where the cable is picked up. The motor car will also haul the train at night, when the cable plant is shut down for inspection. A shoe on each motor truck will take the current from a rail conductor laid outside of the track rails. The cars were built by the Pullman Palace Car Co., of Pullman, Ill., and the electrical equipment was fitted by the General Electric Co., at Schenectady, N. Y.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week was a head collision of freight trains, Oct. 1, at Philson, Pa., on the Baltimore & Ohio R. R. An eastbound train descending the steep grade of the Allegheny mountains got beyond control and could not be stopped at the siding where it should have waited for the westbound train. The train went down the grade at high speed and struck the westbound train, which had two engines. The three engines and 34 cars were wrecked. The bodies of 18 men, all tramps, were found in the wreck, and several of the trainmen were injured. The accident occurred on a grade of about 2.3%, 17 miles long, from Sand Patch tunnel to Hyndman. It is said that 16 cars (or about half the train) had air brakes, and that the brakes were tested satisfactorily at Sand Patch, but that the tramps (large numbers of whom ride on these trains) meddled with the brakes, cutting them out of service.——A double collision of freight trains occurred Sept 30 at Niagara Junction, N. Y., on the Lehigh Valley R. R. A freight train had stopped to cool a hot box and was run into by a following double-header freight train, derailing one engine and the caboose, and throwing them across the other track in front of a westbound freight train. The two engines went down the bank and a number of cars were wrecked, four or five of the cars being destroyed by fire. One man was killed and another fatally injured. It is said that a signal which should have been set to protect the rear of the standing train, was not set at danger until the second train was seen approaching.

◆

A TUGBOAT BOILER exploded Sept. 29 in the East River, New York, near Hell Gate. The tug was the "Robert Lockhart," of the Lehigh Valley R. R., and was towing three heavy coal barges against the tide. The boat caught fire and very nearly drifted on the rocks, but was hauled out of danger by the "Edna B. King."

◆

A BOILER EXPLODED at No. 2 Colliery, Harwood, Pa., on Sept. 28, killing one man and seriously wounding two others.

◆

THE BURSTING OF THE DAM of the lake at the Fair Grounds, Staunton, Va., Sept. 30, caused a flood in Lewis Creek which caused considerable damage to property and the loss of several lives. The accident was due to the high water in the lake, caused by heavy rains.

◆

THE HEAVY GALE AND STORM of Sept. 29 caused widespread damage along the south Atlantic coast. The town of Cedar Keys, Fla., was almost entirely wrecked, and great destitution will result, while a number of persons were killed and injured. A number of the boats of the sponge fishing fleet were lost, with all hands. At Savannah, Ga., the loss by damage to buildings, etc., will probably amount to $1,000,000. Several ships were blown ashore on the coast and in the rivers, plantations were flooded, electric light and power plants shut down. Extensive damage was also done at Baltimore and Washington.

◆

TWO RIVALS FOR THE STEAM ENGINE in its usual form are now receiving much attention, the steam turbine and the gas engine. Which one is eventually to displace the reciprocating steam engine for the direct driving of dynamos is a matter of doubt, but the Westinghouse Machine Co., which builds the well-known Westinghouse steam engine, is preparing itself for either event by embarking in the manufacture of both steam turbines and gas engines. It has recently placed both upon the market. The turbine is of the Parsons type, which has for some years been on the market in England. The gas engine is a new design, the result of some years of experiment by Mr. George Westinghouse. It is a two-cylinder engine, using the Otto cycle, but with a governor which controls the admission of both air and gas in such a way that an explosion occurs at every stroke. The result is a very good regulation, such that dynamos driven directly on the shaft of the engine furnish an entirely satisfactory light, free from flickering. Two of the gas engines are now running in the Pittsburg Exposition.

◆

THE LARGEST INSTALLATION OF WATER TUBE boilers on any steam vessel is that of the Belleville boilers on the new British battle-ship "Powerful." A detailed description of the plant is given in Engineering News of Sept. 25. There are 48 boilers in all, designed to work at 260 lbs. per sq. in., which pressure is reduced to 210 lbs. by Belleville valves. The total heating surface is 69,453 sq. ft., equal to 2.77 sq. ft. per designed horse-power (22,500 I. HP.), and the total fire-grate area is 2,192 sq. ft.

THE PARK ROW BUILDING, 30 STORIES HIGH; NEW YORK CITY.

(With inset.)

The rage for phenomenally high office-buildings still continues unchecked in New York city, and there seems to be at present some rivalry here as to who shall build the highest structure. The design and construction of these very lofty buildings calls for some very interesting engineering work.

The first part of the work of designing such a building is the preparation of general elevations and floor plans, by the architect, but the structural or constructional design is largely an engineering rather than an architectural work, since with the steel skeleton style of construction necessary for these great buildings, the exterior masonry and treatment which are visible in the finished work are merely the clothing and ornament of the steel framework. Nevertheless the general plan and appearance of the structure are the first considerations, and it is, therefore, the architect who is first engaged to prepare the plans, and who may either prepare the structural design for himself or entrust the work to an engineer, subject, of course, to his approval as being responsible for the entire work. In all buildings of this character the architectural design and arrangement considerably complicates the arrangement and detailing of the structural ironwork.

The highest building thus far designed in New York city is the Park Row Building, which is to occupy the site of the old International Hotel on Park Row, opposite the Post Office, and work is already in progress on the foundations. This will be an office building, with stores on the street floor, and a restaurant at the top. The main part of the building will have 26 stories, while at the two front corners will be four-story towers, the total height from the curb to the tops of the cupolas being 386 ft. Below the curb level will be a basement and a cellar. The St. Paul Building, close by, has 25 stories, and is 313 ft. high from the curb (Eng. News, May 7, 1896); while the American Tract Society Building has 20 stories in the main part, three more in the tower, and is 291 ft. high to the top of the roof of the tower (Eng. News, Dec. 27, 1894).

The general appearance of the new building is shown in Fig. 1, which is reproduced from one of the water-color drawings prepared in the architect's office.

The plan of the building is very irregular, as shown in Figs. 3, 12 and 13, owing to the impossibility of securing some of the property at any reasonable price (until the owners of this property found that the new building could be built without it, when their demands at once fell considerably but it was then too late). The building will have a frontage of 103 ft. 11 ins. on Park Row, 20 ft. on Ann St., and 47 ft. 10½ ins. on Theater Alley, while the depth from Park Row to the alley will be 153 ft. 7¾ ins. The area covered will be 15,000 sq. ft., and this is entirely on a deep sand foundation. The foundation will be carried on piles driven into the sand to a depth of about 20 ft., this system having been satisfactorily employed for the American Tract Society Building, where no settlement has occurred. There will be about 3,500 foundation piles of good sound American spruce, free from knots and ring strokes, and having the bark left on. They are 10 to 14 ins. diameter at the head, perfectly straight and 20 to 25 ft. long; and have the heads cut off below the level of ground water, or at 34 ft. 4 ins. below the level of the curb on Park Row. For the Tract Society Building (which was also built by Mr. Robertson) it was specified that the piles should be driven to a greater depth than 20 ft., but it was found difficult to get them down more than 20 ft. without breaking or brooming them, while where they were very close together the piles would sometimes refuse to go more than 10 ft. into the closely compacted sand. For this reason a depth of 20 ft. or to a hard bearing has been specified for the piles for the Park Row building. The piles will be driven about 16 to 18 ins. c. to c., beginning at the center of each pier or group, and working outward, while the rows of piles will be about 24 ins. c. to c. No pile is to be loaded with more than 16 tons, and the allowed pressures are 15 tons per sq. ft. on brickwork, and 40 tons per sq. ft. on granite. The site of the building will be excavated to a depth of 34 ft. below the curb line. An additional 12 to 16 ins. in depth will be excavated between and around the heads of the piles for a clear space of 12 ins. from the piles, and this space will be filled in with a concrete composed of 1 part Portland cement, 2 parts sand and 5 parts broken stone not over 2½ ins. in size. This concrete will be tamped to a hard consistent mass, and leveled off flush with the heads of the piles. The Portland cement used is specified to be of the Stettin or Ooland brands, all of which must be of recent manufacture, and no retempering of the cement will be allowed. The sand must be coarse, sharp and clean. Upon the concrete capping will be laid large granite blocks for bases for the piers, which will be of brick, with granite capstones to carry the grillage beams. The bottoms of these grillage beams are to be 29 ft. 1½ ins. below the finished level of the first floor on Park Row.

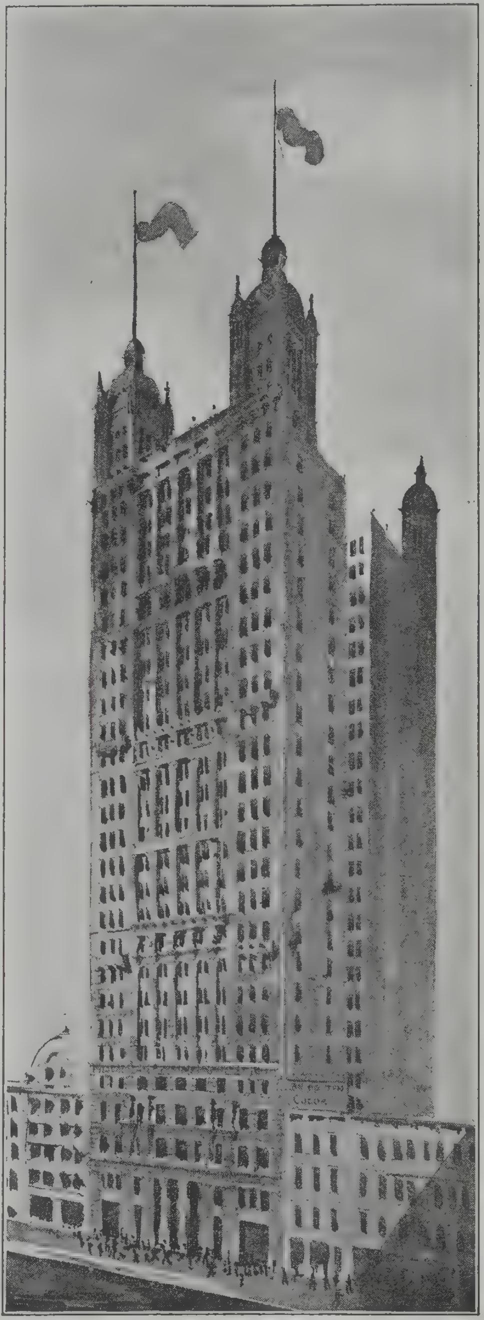

FIG. 1. GENERAL VIEW OF THE PARK ROW BUILDING; NEW YORK CITY.
Architect. R. H. Robertson.
Consulting Engineer, Nathaniel Roberts, M. Am. Soc. C. E.

It will be seen from the foundation plan, Fig. 3, that most of the columns rest on distributing girders, which in turn rest on a grillage of I-beams on two or more of the masonry foundation piers, while some of the interior columns rest directly upon grillages upon isolated piers. Each foundation had to be especially designed for the column loads to be sustained by it, the size of girders and the size and weight of grillage beams varying according to location. The long girder on the Theater Alley front is carried by 61 I-beams, 12 ins. deep, 32 lbs. per ft., 4 ft. long. The girder for columns G7, G8, has 13 15-in. I-beams, 67 lbs., 8 ft. 8 ins. long, and 11 15-in. I-beams, 41 lbs., 3 ft. 4 ins. long. The girders for columns A2, B2, etc., have 20 15-in. beams, 67 lbs., 8 ft. 8 ins. long, and 4 15-in. I-beams, 41 lbs., 3 ft. 6 ins. long. The grillages for isolated column foundations have a lower row of 15-in. I-beams, 45 lbs., and an upper row of 24-in. I-beams of 68 or 80 lbs. per ft. The grillage beams are I-beams of length, depth and number suitable to each individual foundation, and these are laid upon the granite caps of the brick piers, being set in a bed of cement, ½-in. thick, on top of the caps, any difference of thickness of over ½-in. being made up with layers and cross layers of flat steel bars, grouted in cement. Each span of grillage beams up to 5 ft. in length has four cast-iron separators, while where the beams are over 5 ft. long, six separators are used. The separators are box-shaped, with milled surfaces to bear evenly and truly on the top and bottom flanges of the beams.

The distributing girders are of plate construction, having two to four webs, their length ranging from 8 ft. to 47 ft., and their depths from 44 to 96 ins. The typical construction is shown in Fig. 5, and the details of one of the heavy girders are given in Fig. 11, which shows the girder at the Theater Alley front. The weight of this is about 105,380 lbs. for a length of 47 ft. 2½ ins In all cases the web stiffeners are required to have a bearing at top and bottom, Fig. 14 shows the location of some of the girders in relation to the columns. The make-up of some of these distributing girders is given below:

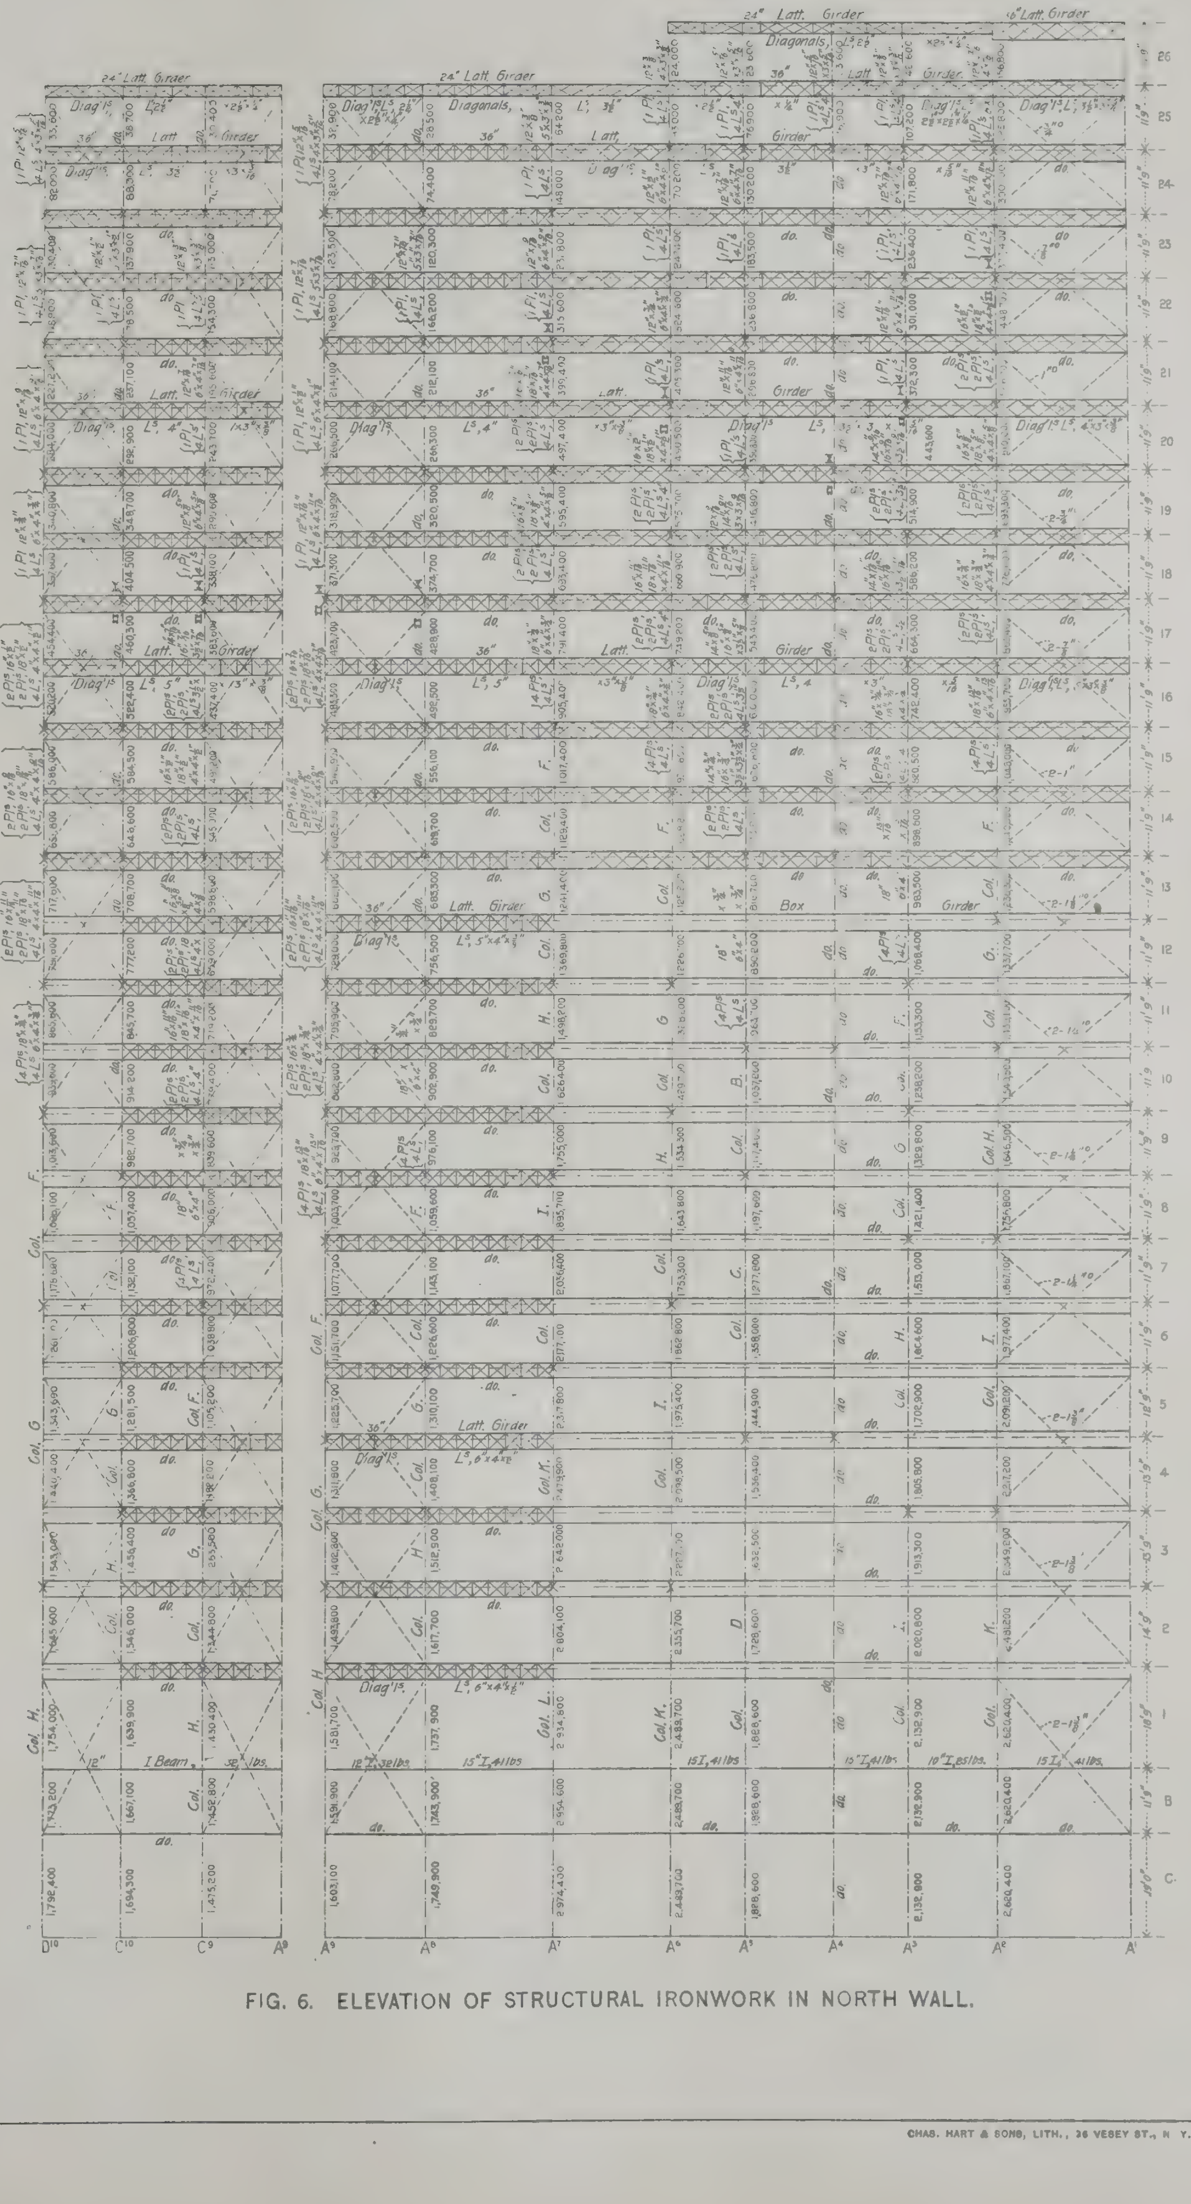

FIG. 6. ELEVATION OF STRUCTURAL IRONWORK IN NORTH WALL.

CHAS. HART & SONS, LITH., 36 VESEY ST., N. Y.

Girders A1, B1, and F1, G1; 4-web plates $\frac{7}{8} \times 96$ ins., 8 angles $\frac{7}{8} \times 6 \times 6$ ins., 6 plates $\frac{3}{4} \times 32$ ins.

Girders A2, B2 ; F2, G2, and A6, B6 are similar but with 6 plates $\frac{7}{8} \times 32$ ins.

Girder A9, D10; 4 plates, $\frac{3}{4} \times 72$ ins., 8 angles $\frac{3}{4} \times 6 \times 6$ ins., 10 plates $13\text{-}16 \times 32$ ins.

Girder F3, G3; 2-web plates $\frac{1}{2} \times 96$ ins., 1-web plate $\frac{3}{4} \times 96$ ins., 8 angles $\frac{3}{4} \times 6 \times 6$ ins., 2 plates $\frac{5}{8} \times 32$ ins.

Girder F''; 4-web plates $\frac{3}{4} \times 44$ ins., 2 cover plates $\frac{1}{2} \times 32$ ins., 8 angles $\frac{3}{4} \times 6 \times 4$ ins.

All columns which do not rest on distributing girders, but have isolated foundations, are supported on short girders on a set of I-beams resting on the grillage beams, so as to distribute the weight evenly over the caps of the piers. The general arrangement of the foundation construction is shown in Figs. 2, 3, 4, and 5. The cellar floor will be level with the base of the granite cap, so that the steel girders will be accessible for inspection and repainting.

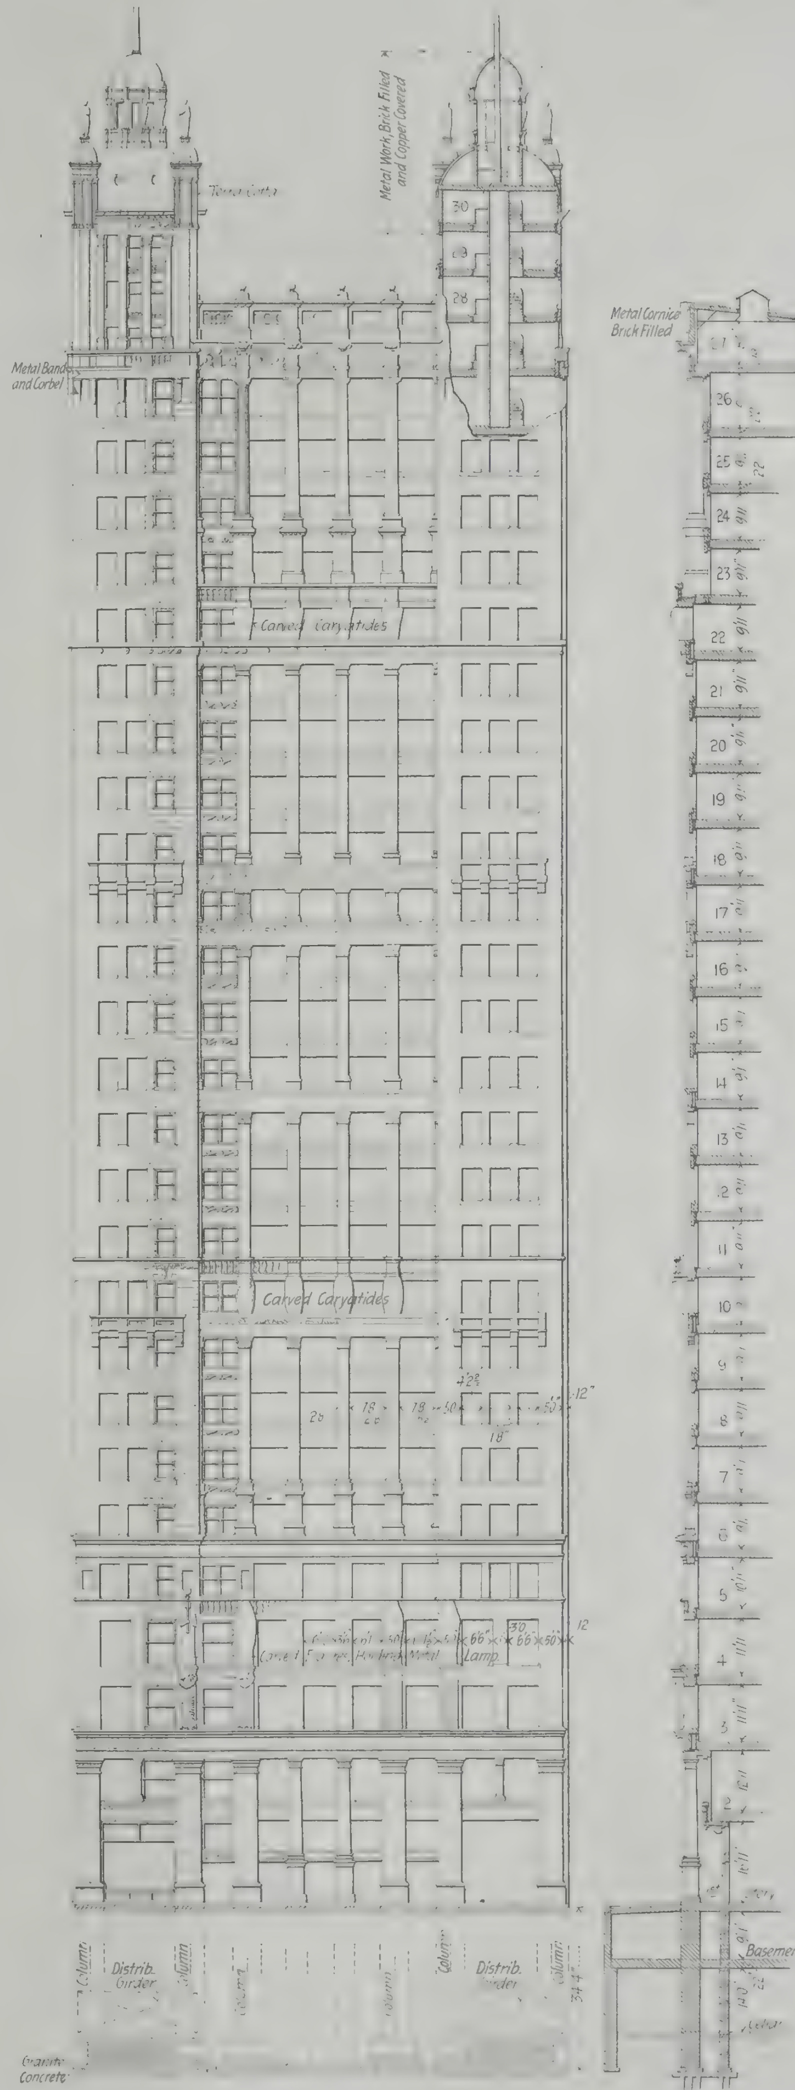
There are practically no two columns of identical section in the entire building, the irregular arrangement preventing any uniform loading, so that each column has had to be designed and built up for the particular load. The loads range as high as 2,900,000 lbs. All the columns are of box section (Figs. 7, 8, 9, 10), some being square and others of rectangular section, while in one case a double-box section is used, Fig. 8. They are flanged at every story, near the floor beams, to support the surrounding masonry. The bed plates are planed to a smooth surface to avoid shimming, and all the columns in the walls are to be carried up 3 ft. above the roof beams, and there connected with a line of 8-in. channels under the balustrade coping. The weight of columns P22 and P26 is about 58,080 lbs. per section of length.

The floor beams are generally composed of two I-beams, with cast-iron separators 5 ft. apart, these separators being the full height of the beams and bolted with ¾-in. bolts. There are three or four separators to each span, so made that the flanges of the beams will be not less than 1½ ins. apart. All floor beam tie-rods are to be ¾-in. diameter, set 3 ins. above the bottoms of the beams. The floor beams of each tier are framed so that the bottom will present two different levels, one 5 ins. above the other. In the area where 15-in. beams are used, the beams and girders will be framed flush (or coped together). Where 10 and 12-in. beams are used they are framed flush and level at the bottom, which is to be 5 ins. above the bottom of section where 15-in. beams are used. The plan of the framing of the first floor, Fig. 12, is reproduced direct from one of the drawings, and shows the general character of the drawings as sent out from the office of the consulting engineer, the illustration being about one-third the size of the original. It will be seen that the irregular plan of the building results in a somewhat complicated arrangement of the floor framing. The horizontal diagonal members are for wind bracing, while the semicircular arrangement at the back is for a group of elevators.

Box and lattice girders connect the columns at the walls. The lattice girders in the light courts are 48 ins. deep over chords, and those in the solid side walls are 36 ins. deep. Those in the light courts have the bottom set 1 in. lower than the 15-in. floor beams, and all have their chord angles ⅜-in. apart to allow of the easy connection or attachment of cast-iron lintels and sills. The outer ends of the light courts are spanned at every other floor by plate girders having curved bottom chords. The elevation of the ironwork of the north wall is shown in Fig. 6.

The main roof over the 25th story will be formed flat, like a floor, and will be sufficiently strong to carry a water tank of 10,000 gallons capacity. The roof over the 27th story (in the middle of the front) will be formed by angle-iron trusses 6 ft. apart, with T-iron purlins 12½ ins. c. to c., to carry safely a load of 100 lbs. per sq. ft. The walls and roof of this portion will be of vertical I-beams, with terra cotta block filling. The roofs of the turrets and lanterns will be of tees and angles, and the turrets will have a metal roof covering. Over the Ann St. front will be a dome, square in plan.

The amount of steel work in the building will aggregate about 9,000 tons. All beams, connections,



Front Elevation on Park Row.

Section through Center Portion of Front.

FIG. 2.—GENERAL ELEVATION AND PART CROSS SECTION.

rods, girders, angles, tees and channels; all built-up sections, and all cantilevers and columns, are to be of medium steel having an ultimate strength of not less than 60,000 lbs., nor more than 68,000 lbs. per sq. in.; elastic limit, half the ultimate strength; minimum elongation, 20% in 8 ins.; minimum reduction of area at fracture, 40%. The metal must bend cold 180° to a diameter equal to the thickness of the test piece, without a crack or flaw on the outside of the bent portion. The smoke flue and all its connections and appurtenances will be of mild steel. No variation of more than 2½% in weight or cross-sectional area will be allowed.

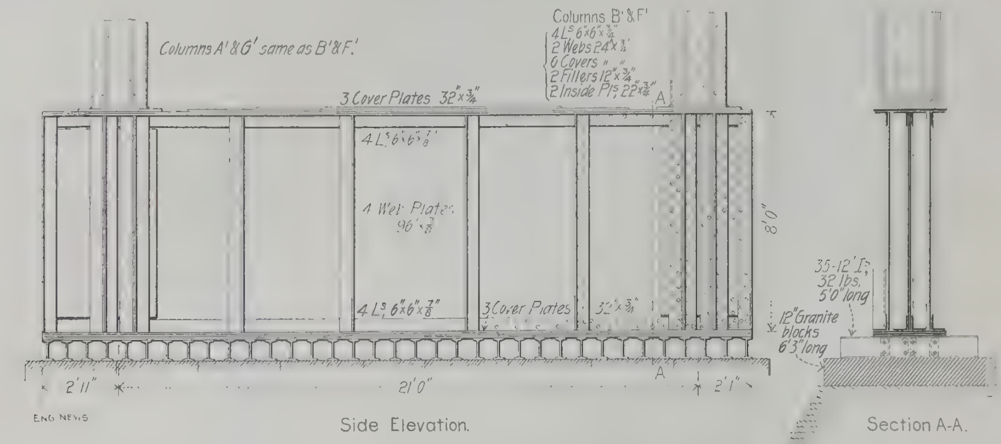


FIG. 5.—TYPICAL DETAIL OF GRILLAGE AND DISTRIBUTING GIRDER.

The specifications provide that all abutting surfaces of compression members, such as columns, shoes, etc., must be planed to even bearings, and all finished surfaces must be protected by white lead and tallow. All surfaces that will be inaccessible after assembling, must be cleaned and well painted (before assembling) with three coats of best red lead paint and oil, or asphaltic or graphite paint. The entire structural work of cast iron, wrought iron, and steel must be cleaned, dried and painted with two coats of paint (as above), and three coats on all portions which will be surrounded by masonry.

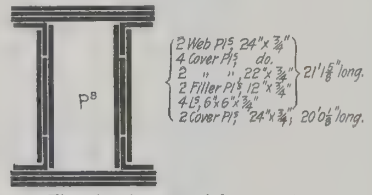

Fig. 7.—Section of Column P 8.

Rivets will be usually ¾-in. and ⅞-in. diameter, the pitch not exceeding 6 ins., nor 16 times the thickness of the thinnest outside plate, nor less than three times the diameter of the rivet. The distance between the edge of the piece and the center of rivet holes must not be less than 1¼ ins., except for bars less than 2½ ins. wide, and when practicable it must be at least twice the diameter of the rivet. The rivet heads must be concentric, with a height of at least 0.6 the diameter of the shank. Rivets will be machine driven wherever practicable. In punching, the diameter of the punch must not exceed the diameter of the rivets by more than 1-16-in., and all holes must be clean cut. The use of drift pins is allowed only to bring together the several parts of one member, and the pins must not be driven with such force as to disturb the metal about the holes. The rivet holes for splice plates of abutting members must be accurately spaced, so that the holes will be truly opposite when the members are brought together and before the rivets are driven.

The wind bracing consists of horizontal diagonal bracing in the floor systems, while the column connections with the box and lattice girders also give great lateral stiffness. There is also a vertical diagonal bracing in the panels between the following columns: G5 and G6, G7 and G9, G8 and G10, A3 and B3, A6 and B6, D6 and D7, and D8 and D9. This is composed of two angles 9-16 × 4 × 6 ins. in the lower stories, and the sizes get smaller in the upper part of the building. There will be a temporary erection bracing, as shown by dotted lines on the iron work elevation, Fig. 6, which consists of 1½-in. rods, with eye ends, pins and turnbuckles.

There will be two steel tanks of 10,000 gallons capacity, one in the cellar and one on the roof. Each will be 14 ft. diameter and 9 ft. high, of 5-16-in. steel plates, with a ½ × 4-in. band around the upper edge. The roof tank will be blocked up 15 ins. above the beams. The steel smokestack will be made in sections, one story high, riveted together, with expansion and contraction joints at every third and fourth story, each section being supported directly on the floor beams of its section. This smokestack will be of steel plate ⅜-in. thick for 100 ft., then 5-16-in. for 100 ft., and then ¼-in. to the top. All sills, mullions and lintels for windows will be of cast iron.

The treatment of the exterior can be credited to no established style of architecture, but may be classed as that of the "American skyscraper" style, the great height, narrow width and necessarily flat front or facade of such buildings rendering necessary a special treatment which it is difficult to make effective. The general appearance of the building, and the treatment of the Park Row front are shown in Figs. 1 and 2. The exterior masonry will be of granite to the top of the third story, then buff Indiana limestone to the sixth story sill on the Park Row and Ann St. fronts, and the remainder will be of buff brick, terra cotta and stone. The brick masonry backing will be of Haverstraw hard-burned brick, laid in cement, and grouted with liquid cement. The exposed portions of the side walls, court walls, and Theatre Alley front, will be faced with IXL brick, specially burned to a hard, impervious, glossy surface. The walls of the light courts will be 16 ins. thick, and the columns in those walls will be fireproof, with not less than 8 ins. of brickwork, the inner course of which is to be of hollow brick. Other columns will have not less than 4 ins. of common brickwork.

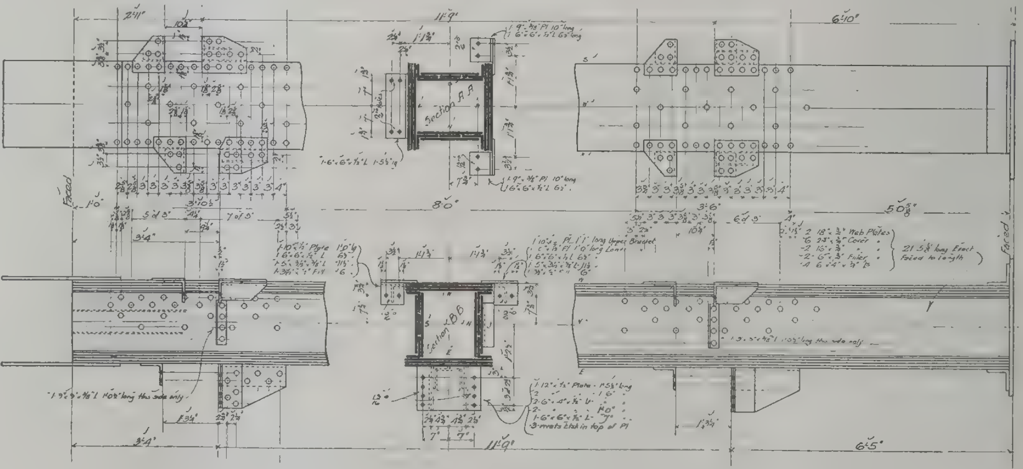

FIG. 9.—DETAILS OF MAKE-UP AND CONNECTIONS OF COLUMNS P 22 AND P 26.

Bluestone caps 24 × 20 × 12 ins. are used for the floor girders. All brickwork below the street will be laid in cement mortar of 3 sand to 1 Portland cement, and the coping will be set and pointed in Portland cement mortar and sand 1 to 1. There is to be a water-proof or damp-proof course laid through the vault walls, and all other walls in contact with earth, being carried up 2 ft. above the surrounding earth or to the level of the curb. This course consists of three continuous layers of hot asphalt or plastic slate and three layers of paper impervious to moisture. The concrete of the roof will be covered with five alternate layers of hot asphalt or plastic slate and four layers of moisture-proof paper, finished off with ¾-in. roofing tiles, gutter and leaders, laid in Portland cement and pointed. The kitchen and serving rooms will have rock asphalt floors. The sidewalk will be of 2½-in. bullseye lights, set in cement in cast-iron frames, with a stone curb 24 ins. wide.

The floors will probably be of terra cotta flat arches of end construction, the blocks being 12 ins. deep for the 15-in. floor beams, and 10 ins. for the others. The blocks will be set in Portland cement mortar, and covered with cinder concrete. The weight of this block construction and top filling must not exceed 65 lbs. per sq. ft. where 15-in. beams are used, or 45 lbs. where 10-in. beams are used. The partitions will be of terra cotta blocks, 3 ins. thick for the basement and all floors except the first floor, which will have 6-in. blocks. Porous terra cotta bands will be fitted, to which to nail the base, chair rail, picture molding, plaster grounds and trim. It is possible that the Roebling system of flooring and partitions will be used, if authorized by the Building Department. In this case there will be a steel ribbed wire cloth and concrete arch, at least 3 ins. thick at the crown, with suspended ceilings of No. 20 stiffened wire netting, leaving 1 in. air space below the bottoms of the beams. The floors would be guaranteed to carry 500 lbs. per sq. ft., uniformly distributed. The Roebling partitions would be 2 ins. thick between finished plaster surfaces. The smokestack will be enclosed by double partitions, with a 4-in. air space between them. The rough concrete over floor arches and for the tile flooring will be cinder concrete, composed of 8 parts clean, dry cinders (no ashes), 2 sand and 1 Portland cement. This will be filled in to within 1½ ins. of the finished floor surface or 3 ins. above the tops of the beams. A similar concrete, 3½ ins. thick, will be used for the flat roof. The roof filling of the towers will be 4-in. porous terra cotta blocks, laid in Portland cement. The entire building will be plastered with

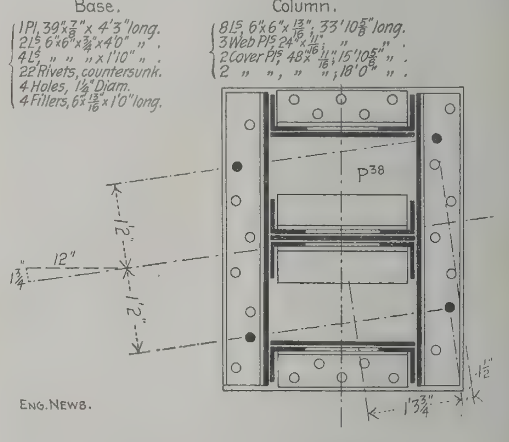

Fig. 8.—Section of Double Box Column, P 38.

a quick-drying material, such as rock or adamant plaster.

In the construction of the foundations, all adjoining walls will be shored up and strongly underpinned with brick work laid in Portland cement, this underpinning being 4 ins. thicker than the wall it supports. The underpinning will be carried down to a depth of 34 ft. 6 ins. below the Park Row curb, and will have a foundation of concrete 12 ins. thick and 12 ins. wider than the wall. Granite columns may be used by the contractor for the underpinning. Sheet piling and bracing may be used to protect the adjoining walls, while the shoring and underpinning are being done, and the braces are not to be removed until the work is thoroughly finished and set.

During the execution of the foundation work the side of the street will be sustained by sheet piling and shoring. Sidewalk bridges are built for pedestrian traffic, these being 6 ft. wide and specified to carry safely a load of 300 lbs. per ft. of the whole area, while the platforms for depositing the construction material must be strong enough to safely carry 500 lbs. per sq. ft. Along the bridges are 7 ft. fences of ¾-in. dressed and matched spruce boards.

The elevator plant for such a building is a very important detail,as it is necessary to carry passengers swiftly, yet easily. The plant will be tested by loading each car with 3,000 lbs. live load, and giving each car 200 full trips up and down within ten hours, running on a uniform schedule. One elevator will be for carrying freight and safes, and will have the front and sides removable, while the platform must be designed to carry a safe weighing 8,000 lbs. The power plant for the elevators will include three Worthington pumps (one triple-expansion and two compound), and a special duplex pump for the freight elevator when lifting safes. Separate elevators will extend from the top main floor up into the towers, as shown in Fig. 2. The elevator equipment is given in detail in the accompanying table.

FIG 13.—PLAN OF THIRD FLOOR, SHOWING ARRANGEMENT OF OFFICES.

The architect of the building is Mr. R. H. Robertson, of New York city, and Mr. A. Pauli is in charge of the building and its erection for him. The constructional steel work was all designed and worked out in detail by Mr. Nathaniel Roberts, M. Am. Soc. C. E., Consulting Engineer, of New York city and Jersey City, N. J., who also has charge of working out all the detail drawings of the steel framework of the structure. Mr. Geo. Shea Dayton, Chief Draftsman for Mr. Roberts, has had a large share in the responsibility for this work. The general contract was let to Mr. John Downey. The contract for the excavation and foundation work has been let to Mr. T. P. Galligan; that for the steel and iron work to J. B. & J. M. Cornell, and that for the masonry to Dawson & Archer. The building is being erected for the Park Row Construction Co., and its cost will probably be in the neighborhood of $2,000,000. We are indebted to the architect and the consulting engineer for plans and information made use of in the preparation of this article.

THE PRESENT STATUS OF THE DISTRIBUTION AND TRANSMISSION OF ELECTRICAL ENERGY.*

By Dr. Louis Duncan.**

It is my purpose to take up the different methods of transmission and distribution of electrical energy and to consider the limits that are actually fixed by the present status of electrical development.

Generating Plants.

A large proportion of the electrical plants in this country are steam plants. In the last ten years we have advanced from small stations using high speed dynamos for light and power distribution to large stations, using, as a rule, low speed direct connected machines. The simple engines that were used some years ago have, in many cases, been changed to compound and even triple expansion engines, and where it is possible condensers have been employed. Some of the latest plants have machinery of the highest possible efficiency, and yet if we consider the price per horse-power of the power generated, we will find that it is greater than we expect. This is partly due to the fact that for both lighting and power purposes the load on the station, is, as a rule, not uniform and the apparatus is not working under the best conditions for economy. In this country electrical energy is principally generated for electric lighting, for electric traction, and for supplying stationary motors, the stationary motors, as a rule, being supplied with current from lighting stations. If we take the load diagram of such stations in large towns, we will find that the average output is not greater than 30 to 40% of the maximum output. We have, therefore, to supply a large amount of machinery corresponding to the maximum demand on the station, while for distribution a large amount of copper is required that is only being used at its maximum capacity for a comparatively short period of the time.

In stations supplying power for traction purposes we find a variation of load, but the variation is a different kind from that found in a lighting station. In the latter the load varies at different hours in the day, but for any particular instant it is practically constant. In the former the average load for different hours during which the station is operated will be practically constant, but there will be momentary variations depending upon the size of the station and the type of traffic. Taking for instance a 2,000 HP. station in Baltimore, I find that the average load is 48% of the momentary maximum load. This difference in the kind of variation for the two types of stations necessitates employment of different apparatus to obtain the maximum economy for each type. For lighting stations, triple expansion engines may be used, while for traction work, where the variation in the load is sudden and

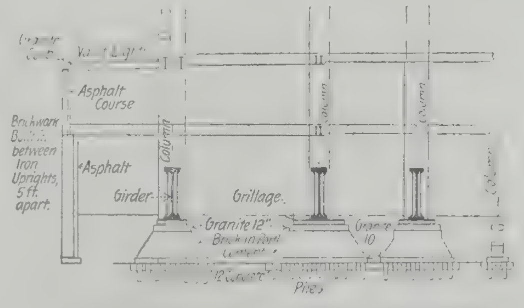

Fig. 14.—Section on Park Row, Showing Foundations and Distributing Girders.

---

*Condensed from the presidential address before the American Institute of Electrical Engineers, Sept. 23, 1896.

**Pres. Am. Inst. Elec. E., Johns Hopkins University, Baltimore, Md.

may occur after the steam is cut off from the high pressure cylinder, it is not well in general to go beyond compound engines, and there is even a question as to whether simple engines are not more economical when condensing water cannot be obtained. In any case, however, it is of the utmost importance as regards economy of operation that the load should be made as constant as possible.

Two distinct types of distribution are used for incandescent lighting in this country—the single-phase alternating current and the direct current three-wire system. At the present time the former does not permit the supplying of power. As alternating distribution is at high potential, it does permit the location of the station where the conditions of maximum economy can be fulfilled. The three-wire incandescent system using low voltages may be used for supplying motors, but the amount of copper necessitated by the low pressure has caused such stations to be located near the center of distribution irrespective of the best conditions for the economical operation of the plant.

With the alternating system it seems impossible to provide even a moderately steady output, but with the continuous current system the motor load during the day gives an average output greater in proportion to the maximum. Some years ago the question of the relative values of the alternating and direct current systems was discussed, and for a while most of the stations installed were of the alternating type. At present the tendency seems rather in the direction of continuous current stations, especially in towns where there is a large demand for current within a comparatively small area. There is a great advantage of direct currents in that they allow the employment of storage batteries, which equalizes the load on the station. In almost all of the large lighting plants, both here and abroad, this plan has been adopted to a greater or less extent and the results have been so favorable that the battery equipments in many of our stations are being increased. The efficiency of batteries in lighting stations is comparatively high, while the depreciation has been greatly reduced, and is not now over 5 or 6% per annum. In most systems, however, the full benefit of the storage batteries is not realized, as the batteries are placed in the station, and while the advantage of an approximately constant load is obtained, yet the further advantage offered in distribution is not secured. I will take this question up later.

In New York, Brooklyn, Boston and Chicago a large proportion of the direct current lighting stations are situated where it is expensive to handle the coal and ashes, and where the economy due to condensation is not obtained. It is also the custom to use several stations instead of a single large station, and this increases the cost of production both in operating expenses and fixed charges. The question arises whether we have reached a point where it will be more economical to consolidate the stations in the best possible location for economical production of energy, and make use of the means of distribution which have been developed in the last few years to increase the radius at which energy can be supplied.

As far as traction stations are concerned, their efficiency and output would be increased by the use of batteries, both because the machinery would be steadily loaded and because the most efficient type of apparatus could be used as is the case in lighting stations. By the consolidation of railroad properties that has taken place in the last few years, single corporations operate electric lines over extended areas. It is the custom to build a number of stations, each running a certain section of the line, the idea being that the decreased cost of copper and the decreased possibility of a shut down would more than compensate for the increased cost of operation and fixed charges. It is, again, important to consider the question whether we have not reached the point where a single station can be built in such a way that there is little or no possibility of any accident causing a suspension of the entire traffic of the system, and where improved methods of distribution will decrease the amount of copper so that it will not exceed that required by the present method of using a number of generating stations.

If storage batteries are used, the two types of variable load belonging to lighting and power stations demand different types of battery. For lighting stations a considerable capacity is required, while the momentary variations of power stations do not require any great capacity, but demand as great a maximum output as battery manufacturers can obtain.

In water power plants the conditions of economy are different. The location of the plant is, of course, definitely fixed, and the advisability of obtaining a uniform load, by means of batteries, depends upon the local conditions. If the water power is limited and is less than the demand, then it might be well to use batteries in order to increase the amount of salable power. Again, if the development is expensive, it might be cheaper to develop a smaller amount of power, pay for a smaller amount of machinery and increase the output by the addition of batteries. These are questions that can only be decided by a knowledge of the local conditions.

Electrical Distribution.

The distribution of electrical energy to consumers as distinguished from its transmission to long distances, has been largely accomplished by the agency of continuous currents although alternating currents have played an important part in incandescent lighting. As I have stated a considerable proportion of current for lighting is distributed at constant potential on the three-wire system, or at constant current on arc light circuits, while power for traction circuits is distributed at approximately constant potential at an average of say 550 volts.

I shall first consider the condition of affairs in a traction system in a large city, where a number of suburban lines are operated. If direct distribution is attempted from a single station, it will be found that when the distance exceeds five or six miles a large amount of copper must be employed to prevent both excessive loss and excessive variation of potential on the lines. On suburban lines it is the latter consideration that usually determines the amount of copper used, and this is especially true on lines where there is a considerable excursion traffic. Even in the city itself, the supplying of sections at distances three or four miles from the station may require so much copper that it would be less expensive to operate separate stations. Several methods other than the direct method may be employed to remedy these difficulties. For outlying lines where the traffic is mainly of the excursion order, being variable both during the day and for different seasons, boosters may be advantageously used. It is perhaps best from reasons of economy to run the boosting dynamos from motors. These dynamos are series wound and are connected to feeders of such resistance that the fall of potential in the wire for a given current is compensated for by the rise in voltage of the booster. There is a decreased cost of copper incidental to this system, due to the fact that the drop is not limited by considerations of regulation—the voltage at the end of the feeder being constant—while the transmission is at an increased potential. If the average station potential is 600 volts, and it is boosted 300 volts, then the copper for a given loss would be decreased in the ratio of 36 to 81. The booster system has the advantage of the direct system when the cost of the additional apparatus together with the increased loss on the line, capitalized, is less than the increased cost of the copper necessary to produce the same result by the direct system. Whether the balance is in favor of one or the other depends on the distance and the variation of the load, and it is indifferent whether the variation in the latter occurs often or not.

If any transforming device is employed to feed a distant section of the line it must be remembered that the capacity of the device must be great enough to look out for the maximum demand on this section. Suppose now that we wish to feed some suburban line where the load has considerable momentary fluctuations but where the traffic is moderately constant during the year. In this case the booster could be used with a storage battery at the end of its feeder, the battery supplying the line. The advantages of this combination are greater than with the simple booster and in many cases they will compensate for the interest and depreciation on the battery and the loss in it. If the arrangement is properly made, the load on the booster and line wire will be practically constant, thus decreasing the capacity of the booster to that required for the average load, while less copper will be required for a given loss. As to the latter point, suppose a given amount of power is to be distributed in 24 hours, say 200 amperes at 600 volts, if the load is uniform, the loss will be proportional to $200^2 \times 24$ hours. If it is all distributed in 12 hours, the loss will be proportional to $400^2 \times 12$ hours, or twice as much. So in the case of the steady load the same power could be transmitted with the same loss with half the copper. It makes no difference whether the variation extends over 12 hours in 24 or it occurs every other minute, the result will be the same. It is apparent then that it is of the utmost importance to keep the line steadily loaded, as well as the station, and this points to the location of the battery near the points of consumption and not in the station. By this system—a booster with storage batteries—it is possible, assuming the same loss, to transmit power to a distance of ten miles with approximately the same amount of copper that would be required for a five mile transmission on the direct system. It would increase the economical radius of distribution twice and the area of distribution four times. A single station could economically supply lines within distances up to ten or twelve miles. If it is desired to still further increase the radius of distribution, it is possible to do this by employing some of the alternating current methods that have come into use. I will discuss these methods later, but at this point I may remark that the use of stationary rotary transformers permits the energy to be transmitted in the form of alternating currents, and to be changed again into continuous currents of any required voltage. These rotary transformers supplied by an alternating current which is transmitted from the station at a high voltage, may be used to feed the line directly or they may be used to supply storage batteries which are connected to the line. In the latter case we have the advantage of decreased size of apparatus, of steady load on the station, and of a minimum cost of copper on the line; which system it would be best to employ would depend upon the distances and the character of the line and load.

Of the systems that I have proposed for city and suburban distribution from a single station three have been successfully employed, namely: the booster system; the booster system with batteries and rotary transformers operating directly on the line. When we consider the advantages of a single station and a steady load, it seems evident to me that many of the large traction systems would do well to concentrate their stations into one and to use the booster system with batteries for their outlying lines, and if necessary use rotary transformers for lines beyond the limit of ordinary suburban work. As to the possibility of the complete shut down of such a station, we have reached such a point in the construction of machinery, both electric and mechanical, that with a proper reserve, a careful system of duplex steam piping, and with fire proof construction of the station, such a possibility may be disregarded; while the batteries would look out for any momentary interruption on the feeders.

Continuous Current Low Voltage Distribution.

Some of the most important stations supplying incandescent lamps are operated on the three-wire continuous current system. In the last few years a considerable advance has been made in the sale of power for motors from these stations, and this has increased the revenue and has given better average output. The tendency in this country has been in the direction of using storage batteries in such stations, and abroad practically every continuous current station uses batteries. As in the case of traction systems it has been the custom in large cities to build a number of separate stations instead of building a single plant and distributing from it. The batteries have been placed in the stations themselves and no attempt has been made to decrease the amount of copper used by employing a number of centres of distribution and giving the main feeders a steady load. The same considerations that apply to stations for traction work will also apply to stations used to supply lights and the same methods of distribution may be used. It would unquestionably be more economical, in many instances, to use single stations, to transmit power from these stations to centres of distribution, where batteries may be located and to distribute from these centres on a three-wire system. A case in point is the system used at Buda Pesth, where the energy is distributed from the central station to rotary transformers at sub-stations, these rotary transformers feeding batteries, current being distributed from these batteries on a three-wire system. The reports of the operation of this station show that it is both economical and successful, and it might well be copied by some of the companies in this country. The gross receipts of some of the large illuminating companies bear such a large proportion to the company's stock that a comparatively small saving in operation would mean a considerable increase in the dividends, and there is no doubt in my mind that by using one power station, with battery substations for distribution, that the operating expenses can be considerably decreased.

Alternating Currents for Lighting.

Alternating currents have been employed for lighting in this country, and they have been especially valuable where a district is to be supplied in which the distances are considerable as compared with a number of customers. It has been almost the universal custom to supply small transformers for each consumer, and while the average size of transformers is greater now than it was a few years ago, yet they are comparatively small. No power has been supplied from such stations, and although alternating arc lamps are used to a limited extent, yet the number is not increasing, and in some cases continuous current arc lamps have been substituted for the alternating. Under these conditions the load on the station is even more variable than in the case of a continuous current supply where motors may be employed, and the constant loss due to the large number of small transformers used, places this system at a disadvantage as compared with the continuous current system. The great advantage it possesses lies in the increased area of distribution rendered possible by the high voltages that are used, together with the possibility of locating the stations where power can be cheaply made. Abroad in the last few years most of the new stations that have been built use continuous currents, although some years ago the greater proportion of them were alternating current stations. It is also the custom abroad to use sub-stations with large transformers for distribution, thus doing away with a considerable part of the constant loss due to the small transformers used here. It is not possible, at the present time, without greatly complicating the system, to obtain a steady load on the station, and the only question that arises is the value of sub-stations, and the possibility of using some form of alternating current other than the single-phase.

Methods of Electrical Transmission.

Coming to the question of transmission of electrical energy as distinguished from the supply to customers from distributing centers, there have been great advances made in the last few years, and these mainly through the introduction of multi-phase alternating currents. Single-phase alternating currents permit the transmission of power to long distances and its distribution for lighting purposes. It is also possible to supply power from such circuits to large motors working under a steady load. It is not possible, however, to distribute power economically for ordinary uses. As most long distance transmission schemes contemplate the substitution of electric motors for steam engines, and as their success will, in many cases, depend upon the possibility of such substitution, single-phase alternating currents are not at present able to comply with the conditions imposed by the desired service. The introduction of multi-phase alternating systems, where two or more alternating currents are employed, the currents differing in phase, has completely changed the situation with respect to long distance transmission. I shall consider briefly the possibilities of such systems and their value as compared with any direct current system.

Continuous Current Transmission.

The first long distance transmission plant was operated by the continuous current system, and even now plants are being built in which continuous current of high potential are used to transmit energy to distances up to 15 miles. As compared with transmission by means of alternating currents, we will find that the continuous current system posseses some advantages and some disadvantages. If we consider the relative cost of the copper in the line for a given amount of power transmitted and for a given maximum potential between the conductors, we will find that the relative amounts for the continuous current and the different alternating current systems, will be as follows:

Continuous current	100
Single-phase alternating	200
Two-phase "	200
Three-phase "	150

We see then that the continuous current has a marked advantage over the alternating current systems as far as the cost of copper is concerned. There are, however, certain practical disadvantages belonging to this system. The high voltages necessary for long distance transmission makes it impossible to distribute the current at the receiving end without first reducing the voltage. With continuous current this can only be done by employing a rotary commutator of some kind. A plan which has been practically and successfully used has been to run a number of dynamos in series at the generating end of a line, while at the receiving end are a number of motors, also arranged in series, which are used to drive other generators to give the required type of current and the desired voltage. It has not been found possible to make either dynamos or motors of any great output, as there are practical difficulties in running dynamos of high potential where the current taken from them has a considerable value. M. Thury has installed a number of continuous current transmission plants that have apparently given excellent results. At Biberist, a transmission of 15 miles is employed. At Brescia, 700 HP. are transmitted over 12 miles at a maximum of 15,000 volts. M. Thury states that generators for 45 amperes can be constructed up to 3,000 volts, and he thinks that 4,000 could be successfully used. These machines, however, are small when compared with the 5,000-HP. dynamos in use at Niagara, for instance, and where the transmission is a large one the great number of machines necessary would be a serious objection to this type of transmission. It will be seen that the greatest possibility of trouble in such a transmission lies at the ends of the line, in the generating and receiving apparatus. It is necessary, no matter what our voltage is, that both the dynamos and motors shall be directly subjected to it, and this with commutated machines will always be a source of danger. If we are to do any considerable amount of lighting from such a station, our energy for this purpose undergoes three transformations before it reaches the lamps, and the efficiency would not be so high as in a corresponding alternating current system. It would hardly be possible to supply motors for ordinary work at the high voltages used for transmission, and the current for them would have to be transformed in the same manner as the current for the lamps. It must be recognized, however, that this system has been successfully used and has given excellent results in a few cases of transmission. Its great advantages lies in the decreased amount of copper as compared with the alternating systems, and in the absence of induction effects, which are a drawback to alternating current transmission.

Transmission by Alternating Currents.

A large proportion of the transmission plants that have been installed in the last few years have been of the alternating current type. These have, as a rule, given satisfactory results, and the installations that are now being erected or planned are almost exclusively on an alternating current basis. The great advantage of this system lies in the fact that it is possible to change the voltage of the current without the use of rotating apparatus, and at once economically and safely. Low voltage dynamos may be used, the voltage may be increased in any desired ratio by stationary transformers, the energy may be transmitted at an increased voltage and at the receiving end of the voltage may again be reduced by transformers. If we compare this method with the continuous current system, we will see that to obtain an alternating current of the required pressure at the receiving end of the line, we would use the same number of transformations required by the continuous current system. We have the great advantage, however, that our changes in voltage have been obtained by the agency of stationary apparatus, which is much cheaper, is more efficient and is safer than that required in the continuous current system. It is possible to increase the voltage by means of transformers to almost any value with perfect safety and with an efficiency as high as 98% or 99%. If then our alternating current, when it has been reduced at the receiving end, is as valuable for distribution as the current obtained by the direct current system, there will be no doubt that alternating transmission has great advantages over continuous currents.

I have spoken of the relative amounts of copper required by the single-phase, two-phase and three-phase alternating currents. I do not think it necessary to explain minutely the difference between these systems, as they are well understood. In a single-phase system a single alternating current is used. In a two-phase system two alternating currents, whose phases differ by 90°, are employed, while in the three-phase system, there are three currents differing in phases by 60°. I shall consider the characteristics of these three systems, as there has been much discussion especially as to the relative value of the last two of them for transmission work. I shall not discuss the various modifications of the systems, but shall confine myself to general considerations. There is no single-phase motor in successful commercial operation that does not require to be started from rest by some outside means. This prevents a single-phase current from being used at the present time for power distribution; and as, in most transmissions, the distribution of power is an important item, single-phase currents are not suitable for this purpose. In a two-phase system the currents are usually carried on separate pairs of wires, while in the three-phase system, three wires are generally used, a common return being unnecessary as the sum of the currents is zero, unless the circuits are unbalanced. In distributing on the three-phase system, a fourth wire can be employed, as it gives an advantage in the amount of copper used.

In all these alternating systems the great difficulty lies in the fact that the inductance of the circuit causes the current to lag behind the electromotive force. This decreases the amount of energy transmitted by a given current at a given voltage; it causes a drop in the voltage of the line, and it increases the armature reaction of the dynamo for a given current. The total inductance of the circuit is made up of the inductance of the transformers, of the dynamos, of the receiving apparatus and of the line. In the case of transmission to very long distances the line inductance is a large proportion of the total, while the inductance of the receiving apparatus depends upon whether lights or motors are to be supplied and upon the construction of the latter. When the different wires of the multi-phase system are fed from windings on the same dynamo armature, then the drop in voltage due to any excess of load on one of these circuits cannot be compensated for on the dynamo itself. If the amount of current and the lag of the current is the same for all of the circuits of the system, then it is easy by a compound winding of the dynamo, or by changing the current in the field winding, if there is no compounding, to keep the voltage constant at either the sending or receiving end. When the load on the different wires of the system is not the same, however, it is, as I have stated, impossible to keep all of the circuits at the proper voltage. Where a two-phase transmission with separate circuits is used, then if the separate circuits are wound on different armatures, each can be regulated to give a constant voltage at the receiving end. This is the case, for instance, in the large dynamos built by the Westinghouse Company for use at the World's Fair in Chicago. The difficulty due to the uneven loading of the circuits is specially marked in the case of the three-phase system, and it is one of the principal objections that have been urged against the employment of this system for distribution. It should be pointed out, too, that it is not enough to balance the quantities of current for the three-branches of the system, but the character of the current must also be considered. A non-inductive load on one wire, with an inductive load of equal value on the others would cause an unbalancing just as if the currents differed in amount. In most of the transmission plants that are being operated and that are proposed, it is required to run both lamps and motors from the same circuits, and while a slight variation of potential on the motors would not cause any particular trouble, yet the successful operation of the lamps requires a practically constant voltage. I think, however, and the same grounds have been taken by others, that in any practical transmission of considerable size, it is possible to so balance the loads that this difficulty will not exist to an extent to cause any serious trouble. When the distributing part of the lines is reached it is usually the custom when a three-phase transmission is used to employ four instead of three wires. As for line induction in the two-phase and three-phase systems, there is no question that the latter has an advantage in this respect. By suitable arrangement of circuits the line inductance can be brought to a minimum, and this is of the utmost importance in long distance transmission. I will not take into account the supposed increased efficiency of three-phase motors and dynamos as against two-phase apparatus, as there is a question as to whether a superiority exists, but simply considering the decreased amount of copper required and the decreased inductance of the line, there is no question, in my mind, that for transmission, the three-phase system is superior to the two-phase. It is well known, of course, that the inductance of the circuit can be, in some measure, compensated for by the use of condensers or over-excited synchronous motors. The first of these remedies is, however, a very uncertain quantity commercially, while the second should be used as much as possible, that is, as many synchronous motors should be connected as is practicable. The best remedy, as things stand at present, lies in the careful construction of the line and the apparatus, so that the effects, although they exist, can be reduced to a minimum.

It has been shown by Mr. Scott, and others, that it is possible to transform a two-phase into a three-phase current, to transmit it and to transform it back again to a two-phase current. This will allow us, if we wish, to use two-phase dynamos for generating the current, to transmit with the advantage incidental to the use of three-phases and at our reducing end to use two-phase circuits for transmission. This has some advantages as far as balancing the voltage on the circuits go, and it has been proposed in the case of several plants whose installation is being considered.

Looking broadly at the value of alternating transmission as against continuous current transmission, we have a gain in the simplicity and safety in the transmission, and at the distributing end the use of multi-phase currents enables us to supply both lamps and power with an economy and success comparable to that of the continuous current system. If it is necessary to use continuous currents for certain types of distribution at the receiving end, they can be obtained by the use of rotary transformers, by which the alternating current is transformed into a continuous current. These machines have approximately the efficiency of corresponding continuous current dynamos, while the output for a given size is about 50% greater.

Possible Voltages and Distances of Transmission.

A number of calculations have been made as to the possibility of transmitting electrical energy to very long distances. If the question of cost of transmission alone is considered, then where water powers or culm heaps are within distances of 100 miles of some large center of consumption, it has been shown that it would be profitable to generate and transmit electrical energy. In these calculations, however, voltages are assumed that have never been employed for commercial plants, and whose availability is problematic, while sufficient stress is not ap-

(Continued on Page 235.)

Plants for Long-Distance Electric Power Transmission.

Name.	Type.	Distance, miles.	Line voltage.	HP.	Remarks.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5 00; 6 *months,* $2.50; 2 *months,* $1.00; *Single copies,* 15 *cents. To all other countries in the Postal Union, add* $2.08 *per annum* (4 *cents per number*) *to above prices for postage. No club rates allowed. Mailing addresses may be changed at will by sending both old and new address. We shall be obliged if subscribers who fail to receive their papers promptly will notify us without delay. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number* 326 *means that subscription is paid to the* 32d *week* (*that is the issue of Aug* 6) *of the year* 1896; *the change of these figures is the only receipt sent, unless by special request.*

In the description of the Water Power and Electric Transmission Plant of the Big Cottonwood Power Co., in our issue of Oct. 1, we neglected to state that the photographs which accompanied the article were furnished by the courtesy of the General Electric Co., through its representative, Mr. J. McGhie.

◆

The notable increase in exports of American manufactures during the present year was discussed editorially in our issue of Aug. 13. We are now able to present figures showing how considerable and rapid has been the growth of our exports of manufactured goods during the past four years and especially during the past year:

Year.	Exports of manufactured goods from U. S. during first 8 months of year.
1890	$99,887,607
1891	113,532,976
1892	99,125,836
1893	113,618,131
1894	118,049,055
1895	129,441,726
1896	163,112,670

The "Journal of Commerce," from which we take the above table says:

> It will be observed that the increase in exports of manufactures for eight months is larger this year than for any previous year in the commercial history of the country. The increase over six years ago is nearly 66%, and would soon give the United States a firm footing in manufacturing exports if it could be repeated through successive series of six years.
>
> The details of the manufacturing exports for August last have not yet been fully compiled at the Bureau of Statistics. If they follow the record of other recent months, however, they will show that a large part of the increase is in classes of goods in which American skill and inventive genius are important factors. There has been a large increase of the export of refined mineral oil and of copper ingots, but the increase in these items does not begin to represent the total increase. The increase in the export of bicycles, electrical and scientific apparatus, stationery and other manufactures of paper, and railway cars and locomotives indicates that the United States have little to fear from foreign competition in these articles.

The success of American manufacturers in securing foreign orders during the present year is something of which the nation may well be proud. It is to be hoped that the trade which has been fairly won in open competition with the manufacturers of Europe may be held from this time forward. As we said some weeks ago, there is no reason why the greatest manufacturing nation of the world should not excel all others in its exports of manufactured goods.

◆

The separation of ashes and other non-organic matter from household garbage is becoming a troublesome question in many of our large cities, and will soon be a subject of anxiety, if not of controversy, in smaller cities and towns. It has been forced to the front largely through the adoption of garbage utilization systems, which can only be profitably operated upon pure garbage, and hence require the separation of ashes, paper, etc., from the mass. But experience and reflection is teaching that all these non-organic matters in city wastes, if kept free from the contamination of the garbage can, are perfectly sanitary and thus are in no more need of expensive treatment by cremation than by utilization processes; nor do they need to be towed for miles out to sea, nor hauled for miles into some remote suburb of a city. The clean ashes are a valuable filling material. The rags, bottles, paper and various other materials are either of some commercial value or may be easily reduced to small bulk without offense by burning. It has been claimed by some of the manufacturers of crematories, that they prefer ashes mixed with the garbage on account of the fuel value of the unburned coal, but where a longer haul is required to cart ashes to the crematory than to low lands where they may be used for filling, the force of this claim is reduced or lost altogether, especially as the ashes must be handled twice at the works, once before and once after treatment, and still remain for final disposal.

New York city has, since Aug. 1, been compelling the separation of garbage from all other refuse, in preparation for the opening of the garbage utilization plant now under construction. If the system can be enforced in New York with its large apartment houses and crowded tenements, it certainly ought to be practicable in smaller places. True, New York has well organized health and street cleaning departments, which are absolutely essential to the success of the plan. Other communities may have the same if they will.

◆

Going almost to the other extreme in point of size, the town of Montclair, N. J., a suburb of New York, with some 12,000 inhabitants, is trying through its board of health to enforce the separation of garbage from non-organic material. The method of garbage disposal in vogue at Montclair, is the primitive but sanitary one of burying beneath a few inches of soil. Farm land is leased for the purpose, but the lease prohibits the dumping of matters that will unfit the land for future cultivation. This provision, coupled with the fact that the haul is a long one, and the expense of trenching for and covering ashes altogether unnecessary, has led to the inauguration of an attempt to prohibit public scavengers from hauling mixed garbage. There are plenty of places where by short hauls ashes may be used for filling, but right here the Montclair board of health experienced one of the greatest difficulties in connection with its work. Ashes mixed with garbage, and sometimes garbage alone, were frequently used to fill in land intended for immediate use as building sites. In one instance, a property owner was fined $50 for allowing mixed garbage and ashes to be dumped in such a manner.

In view of the attempts of so large a city as New York and so small a town as Montclair, the controversy at New Orleans, briefly detailed at the close of an article in another column, seems puerile in some of its details. The city of New Orleans entered into a contract with a company to remove and dispose of the garbage of the city, the contract specifically stating that ashes and other refuse should not be mixed with the garbage. The citizens have failed to perform the separation, the company has refused to take mixed garbage, the city council has voted to annul the contract, and the matter is now in the courts. It is alleged in behalf of the citizens that carrying out the clause of the contract relating to separation would compel them to perform menial service for the profit of a corporation, an argument which appears to be a cross between a legal technicality and a political stump speaker's style of argument. The necessity of separation and its real advantage does not seem to be realized by the people, who appear to consider themselves imposed upon by the company and to forget that the contract is specific on the points named, and the company is only insisting upon its rights under the contract.

◆

How important the construction of fireproof buildings has become, as a factor in the consumption of iron and steel, is well illustrated by the lofty Park Row Building, which is illustrated on our inset sheet this week. The total metal in this structure will reach in round numbers 9,000 tons. This is as much steel as would be required to lay 100 miles of track with 50-lb. rails, so that the construction of this single building furnishes as much business to steel works, blast furnaces and iron ore miners and shippers as the construction of a railway 100 miles in length.

Still more impressive is the comparison with bridge work. The famous Memphis bridge across the Mississippi River has the greatest span of any truss bridge in the world, except the Forth bridge, but its main cantilevers and the side spans with a total length of about 2,600 ft. weigh 7,000 tons, or 2,000 tons less than the steel in the Park Row Building. Comparing with another class of bridge work, an ordinary country highway bridge of 100-ft. span may have perhaps 500 lbs. of steel per lin. ft. in its trusses and floor, or 25 tons in the whole structure. It will be seen that no less than 360 such spans could be built, reaching, if placed end to end, nearly seven miles, with the steel which will be placed in the Park Row Building.

◆

And this matter of the weight of the structure is of much interest in connection with the much-talked of question as to the stability of such very lofty structures under high wind pressures. We account it a remarkable instance of high wind pressures when an iron bridge is blown down; but the above comparison shows that for a given area of base, the weight of the metal work in even the heaviest bridges is trifling compared with the weight of metal in a modern "sky-scraper." Engineers accounted it a well-nigh inexplicable phenomenon when a few years ago a wind lifted from its piers an uncompleted span of the Louisville & Jeffersonville bridge, weighing 1,000 tons, and dropped it in the river. But this span covered a length of 550 ft. and a breadth of 32 ft., while the Park Row Building has a frontage of 156 ft. and a depth of 104 ft.

Of course the weight of the metal-work in the building is only a part of the weight of the structure. Besides the metal-work we have the weight of floors, partitions, ceilings, plastering, fireproofing, and the weight of the contents of the structure. Probably the entire weight of the building when completed and occupied is not less than three times the weight of the steel in its framework, or a total of 18,000 tons. What these figures represent in the way of mass and inertia, and resistance to any external force such as wind pressure is difficult for even an engineer to fully comprehend; but the comparison, when carefully made, between the mass of such a structure and the pressure that even the most powerful gust of wind might momentarily exert against it, gives one full confidence in the stability of the building.

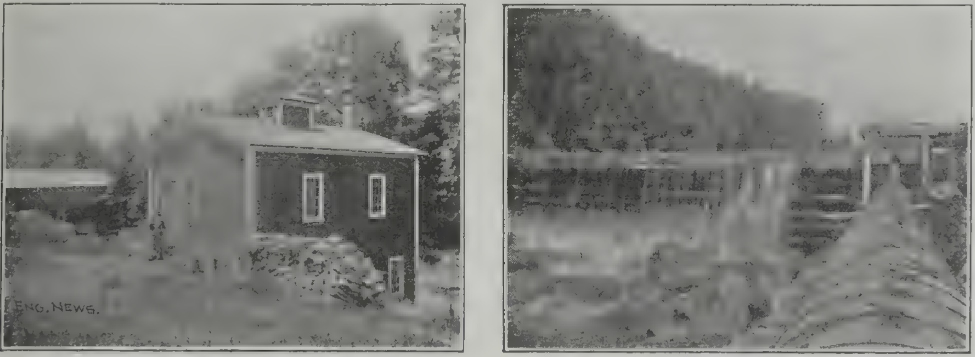
THE CHEAPEST ELECTRIC LIGHTING PLANT IN THE WORLD.

It is quite a common thing to see in the displayed head lines of the daily newspapers the statement that this or that or the other thing is the largest or longest or smallest or shortest, or whatever particular quality is named, in the world. If one stops to analyze this statement, he must necessarily reach the conclusion that what is meant is merely that the writer of the description in question does not know of anything in existence that is larger or longer, or whatever the particular characteristic may be, than the thing of which he writes. For however wise he may be or however broad his experience, it is quite sure that his knowledge is not world-wide; and that whether he be an expert or amateur, there is a possibility or a probability that other things of which he has never heard may excel that of which he writes.

We are not in the habit of taking the daily newspapers for a guide, but in this instance we have concluded to copy for once their practice in this respect and to call the electric lighting plant which we are about to describe, the cheapest in the world. The reader will understand from the above explanation that we give no guarantee that there may not be other cheaper plants somewhere in existence. We simply assert that we have never heard of any such, and further that the circumstances in this case lead us to believe that electric light is being furnished by this particular plant at a cost about as small as would be possible under favorable conditions anywhere.

It is not alone because of its cheapness that this system is of interest. It is a notable instance of an enterprise carried out by a municipality with remarkable economy and success, and it is typical of what has been and may be done in hundreds of small towns to furnish them a cheap and convenient system of street and private lighting to replace the dim kerosene lamp and lessen the consumption of the world's fast diminishing store of petroleum.

The plant we are to describe is located in Johnson, Vermont, a small village in the heart of the Green Mountains, about 30 miles south of the Canadian line. The population of the village is about 600. Its assessed valuation for taxing purposes is a little short of $225,000. It contains two or three small manufactories, and the churches, school buildings, stores, etc., which one would expect to find in a New England village of its size.



View of Power House. View of Dam and Penstock.

POWER STATION OF THE ELECTRIC LIGHT PLANT AT JOHNSON, VT.

The residents are, with few exceptions, people of very modest incomes, living plainly and simply, and a dollar goes as far in the payment of living expenses as five dollars would go in a large city.

About the only one of Nature's gifts with which this region is lavishly blessed, is water power. Within the limits of the township, mountains rise in various parts to an elevation of some 2,000 ft. above the valley in which the village lies, and the water power which runs to waste in the township aggregates probably over a thousand horse-power. Within the bounds of the village itself there has been for several years an abandoned mill-dam, which once furnished power to a large saw-mill. With the exhaustion of the timber supply the saw-mill was dismantled, and the water power was left unused.

Up to the time when the electric light plant we are about to describe was installed, kerosene was, of course, the sole illuminant. The streets were not lighted at all save as an occasional public-spirited citizen maintained a kerosene street lantern in front of his house. But stumbling along dark streets and living in dimly-lighted houses, while water power ran to waste close by, was an anomaly which at length attracted the attention of some of the more enterprising residents, and after a careful canvassing of ways and means, a village corporation was organized and the work of installing an electric light plant was begun. The abandoned mill dam and mill site above referred to was purchased for a small sum; the dam was rebuilt in a substantial manner, and on the site of the old saw-mill a small wooden building was erected for a power house. The old Humphrey turbine, which had formerly run the saw-mill was purchased with the mill site. It is a vertical 33-in. wheel, rated at 45-HP., and runs at 160 revolutions. A round wooden penstock leads to it from the dam, a distance of some 50 ft., and is hooped with round iron bands, such as are used on wood stave pipe in the West (illustrated and described in Engineering News, Jan. 5, 1893). The accompanying views show in one case the dam and penstock and in the other the power house. It will be noticed in the view of the dam that the clear water of the mountain stream as it falls over the crest in a thin veil is so perfectly transparent that in places it is not seen at all in the photograph.

The power-house machinery is very simple. A bevel gear on the vertical turbine shaft drives a gear on a jack shaft; and from a large pulley on this jack shaft a belt runs directly to the dynamo pulley on the floor above. The belt is a two-ply leather belt, and it is of interest to note that such few stoppages as have occurred since the station began running have been chiefly due to this belt.

The dynamo is a Wood alternating current machine, built by the Fort Wayne Electric Co., and rated at 750 lights, or 37 amperes at 1,000 volts. The power house has a rock foundation, and the masonry pier supporting the dynamo rests on solid rock. A small independent dynamo driven by a belt from the main dynamo shaft furnishes a 110-volt current to excite the field of the larger machine.

The switch board is of skeleton wooden construction and carries the lighting arresters, ammeter and volt meter, switches for the house lighting circuit and for the series circuit, a converter and a rheostat. It will be understood that the system in use is the one which has come into great favor within a few years for lighting small towns, in which the street lamps are connected in series and take current from the same dynamo which furnishes current to the converters for the house lighting. The street lamps are of 30 c. p. each and are placed on the same poles that carry the wires of the primary circuit. They are set at a height of 15 ft. beneath a reflector shaped like an inverted cone, with an angle of about 165°. The lamps are spaced 125 ft. apart. There are 53 of these lamps on the series circuit, and 7 other street lamps take current from the same converters that are used for house lighting.

These converters are placed on the poles of the street circuit and are small enough in size to be inconspicuous. The total extent of the primary circuits is about 1¾ miles.

Originally the system was projected solely for street lighting, but it was soon seen that to obtain light for private use was a much more important end. At present some 900 lamps are connected on the house circuits, and more are continually being added. The interior wiring was done at the outset by the contractors who erected the street circuits, and additional wiring is now done by the engineer in charge of the power plant.

Turning now to the operation of the plant, the most notable feature is the practice of running the station only during the hours when light is needed. The dynamo is started in the afternoon as soon as any lights may be needed, often before sundown on a stormy or cloudy day, and runs till 11 p. m. From the last of September until April the station is also operated from 5 a. m. until daylight. The street circuit is not turned on until the streets become so dark that the lights are actually needed. On very bright moonlight nights the street circuit is not operated.

The lighting of the streets is exceedingly satisfactory and fully exemplifies the superiority of incandescent lights over arc lights for street lighting, except in cities of such a size that brilliant street lighting can be afforded. For the average town or city of moderate size, much more satisfactory results will be obtained in street lighting if a given amount of money be expended for incandescent lights than for arc lamps. Popular ideas on this subject are often at fault. Single arc lamps at street intersections with long spaces in total darkness between, do not give as useful a light as twice the number of incandescent lamps, equally distributed. The advantage of placing the street lamps on a series circuit is that the cost of converters for these lamps, and the considerable percentage of current loss in the small converters is entirely saved.

We have been thus full in our description of the plant at Johnson in order that the figures of cost which are to follow may be understood and appreciated. The total cost of the water-power mill site, water-wheel, power-house, dynamo, and entire electric apparatus, poles, converters, street circuits, etc., complete, ready for operation, was in round numbers, $5,600, of which the principal items were as follows:

Water-power privilege, mill site, dam and turbine	$1,150
Repairs on dam, penstock and wheel tub	410
Stone foundation for power-house	84
Power-house (above foundation)	350
Pulleys, shafting, etc.	117 85
Belting	45.54
Dynamo	1,175
All other electrical machinery in power-house, and converters, poles, wires, erection, etc. (let in one contract)	1,850
House wiring (portion paid by village)	300
Consulting electrical engineer	33.10

The annual cost of operation is astonishingly small. The plant was first put in operation in January, 1895. One man is employed at a salary of $425 per annum, has the entire charge of the plant, and the hours of running are such that he not only requires no assistant, but is able to do house wiring, read meters and all other necessary work in connection with the station during the day hours. He is the only salaried employee of the corporation. The other expenses of operation are exceedingly small. The following are the principal ones, estimated as closely as possible:

Insurance (actual)	$29.25
Oil	2.00
Printing, stationery and postage	10.00
Lamps (for street lighting)	50.00

During the 20 months since the system was put in operation the repair account has been so small as to be almost nil. Two or three new steps were made for the water-wheel, and the commutator of the exciter dynamo was turned smooth, and this, with other trivial repairs, was chiefly done by the engineer of the power station, thus involving no additional cost.

The fixed charges of the plant amount to $244 per annum. The plant was paid for by the issuance of $4,000 in bonds bearing interest at 4%, and the borrowing of $1,400, which will be paid off from the surplus receipts of the corporation as they accumulate.

Turning now to the other side of the account, the revenue of the plant, the following is the schedule of rates charged for private lighting:

Stores, Offices, Etc.

For each light	$3.00
Each light in cellar or back room	2.00

Hotels.

First light in each room, except sleeping room	$3.00
Each extra light in each room, except sleeping room.	2.00
First light in each sleeping room	2.00
Each extra light in each sleeping room	1.00
Each light in bath-room or water-closet	3.00
Each light in barn or livery stable	3.00

Public Halls.

Each light	$2.00
Each foot-light	1.00

Churches and Society Halls.

Each light	$1.00

Private Residences.

First light in each living-room or hall	$3.00
Each extra light in each living-room or hall	1.50
Each light in cellar	1.00
First light in each sleeping room, bath-room and pantry	1.50
Each extra light in sleeping room, bath-room and pantry	1.00
Each light in barn or shed	1.00

Meter Rates.

One-third of a cent an hour, to apply only to lighting private residences, churches, halls, hotels and manufacturing establishments. Meters to be furnished by the Village at the expense of patrons.

Minimum rate, 70 cts. per lamp per annum.

Outside Limits of Village.

Same rates as above, except that each patron is to be at the total expense of wiring, and to pay to the Corporation $1.20 for each light installed.

Regulations.

The cost of inside visible wiring will be $2.25 per light.

The Village will at any time before the contractor completes his contract wire buildings with visible wire for $1.25 per light; concealed wiring at actual expense above this, the owner to furnish lamps and fixtures in all cases. This is done as an inducement to patrons to take the light at once. All renewals to be furnished by the Village, at the expense of patrons.

Bills will be rendered semi-annually in advance, on the first days of January and July in each year, and must be settled within 30 days or the lights may be turned off without notice.

In case of deficiency of light, or any defect, notice should be given forthwith at the office that the defect may be remedied without delay.

Landlords will be held responsible for rent of lights used by their tenants.

The Village reserves the right to turn off lights in case the rents, or bills for wiring or supplies, are in arrears. or in case of violation of any rules pertaining to lights or plant. There will be an extra charge of $2 for turning on the lights again.

Rates for incandescent lights are based upon 16 c. p. lights and are to be increased or decreased proportionately as the power of lamps are increased or decreased: Providing, that not less than the price of a 16 c. p. light shall be charged for any one room, and that the price of three 10 c. p. lamps shall be the same as two 16.

All lights, meters and wiring to be subject to inspection by order of Trustees at all times.

A room which is divided by an archway will be considered as two rooms and lights in the same will be charged for accordingly.

The above rates read like a romance, it must be confessed, to users of electric light in the cities, who are accustomed to pay the time-honored rate of 1 ct. per lamp hour for electric lighting; but, as will be seen later, these rates, low as they are, are considerably above the actual cost of the light to the village corporation.

About 20 meters have been set, and in the first year of operation the total revenue from current furnished, both through meters and to lamps charged at annual rates, was in round numbers $1,000.

Besides the revenue from this source the street lighting is paid for in an indirect way. Each year the township has voted an appropriation of $200 toward the expenses of the electric lighting system. This is done on the basis that the street lights are as much of a benefit to those living outside the village, who use its streets when they drive to town, as to the dwellers in the village.

We may then sum up the results of the first year's operation of the plant as follows:

Operating expenses (about)	$525
Interest charges	244
Total outlay	$769
Receipts from private lighting	$1,000
Received from township	200
Balance of profit	$431

The increase in the number of lamps since the plant was first installed is such that for the current fiscal year the net earnings of the system will probably be between $500 and $600.

It is commonly said in criticising such figures as these that operating expenses are low because all the machinery is new and the repair account is small. It is undoubtedly the case that in making up the accounts of every such enterprise, the element of depreciation should be covered by adding a percentage of the first cost. What should this percentage be? In the present case it will be seen that on the water-power and real estate there is no depreciation. On the powerhouse machinery the depreciation is very small. The poles are of cedar and will probably have a life of not less than ten or a dozen years. As for the element of risk which is ordinarily to be taken into account—the chance of the machinery growing obsolete in the course of years—this is of little importance here, for the system installed is sufficiently good to satisfy the users for at least 20 years to come, no matter what advances may be made in artificial lighting. Suppose we estimate the cost of the part of the plant which is subject to depreciation at $4,000, and say that the allowance for depreciation must be such as will replace it at the end of 20 years. Then figuring compound interest at 4% we find that the annual charge for depreciation must be 3⅓% in order to effect this. This makes a charge for depreciation of $133 per annum (3⅓% of $4,000). Adding this to the operating expenses and interest charges we find the total cost of electric light per annum in Johnson village as almost exactly $900 per annum.

As we have shown above, the receipts at the start from private lighting alone were in excess of this, and with the increase in the consumption of light which is steadily going on, it is apparent that the surplus receipts will soon pay for the plant, so that it will be owned free of debt by the village. This increase of patronage, moreover, while it may necessitate the installment of some machinery of greater capacity later on, will not increase the operating expenses to any extent. The principal item in the operating expenses is the salary of the engineer; and he could operate the station alone as at present, even if it supplied twice or four times as many lights. It is not at all improbable, therefore, that a few years hence electric light may be supplied in Johnson at a considerably less actual cost per lamp even than at present.

The most common test of an electric light plant with its users is the frequency or the reverse of its breakdowns. Nor is this an unfair test on the whole; for an electric light station should be so designed and so operated that a breakdown wholly disabling the station should be made as remote a possibility as circumstances will permit. Of course in the Johnson station anything like duplication of machinery was not attempted; but in the 21 months of its operation there have only been two nights when the station was not run. In both cases the trouble was due to the wetting of the belt from a leaky pipe, which softened the cement with which the belt is made up. On one other occasion the station was shut down at 10 p. m. instead of 11 p. m. on account of the wearing down of the turbine step, causing the wheel to drop till the bevel gears slipped.

It may be of interest to inquire in what respects the plant may be criticised. Probably the most notable feature is the variation in candle-power of the lamps. The water-wheel gate is operated by hand and is opened or shut by the engineer at the station as the switchboard instruments show the increase or decrease of the load on the circuits. This intermittent regulation makes a variation in the candle-power of the lamps, which, in a city, would cause some complaints from the patrons of the station. Here, however, it appears to be accepted with equanimity, as a trifling matter and one not worth much expense to overcome. An automatic water-wheel governor of the ordinary Snow pattern is probably too slow to give much better results than hand regulation. A governor of the newer, quick moving patterns would be too expensive to be afforded.

A more important feature in which the station design will soon prove defective is the deficiency of the water-power. This has already made itself felt; and the turbine is to be replaced by a more efficient one in a short time; but this will probably give only temporary relief. Eventually it will probably be necessary to raise the dam some 10 ft. or more, which can readily be done by purchasing a little-used water-power on the same stream some 40 rods above. This would probably be sufficient for many years to come, as the village, like most country villages in Northern New England, cannot look forward to any considerable increase in size.

The Johnson electric light plant is very interesting as an example of municipal operation of a public lighting system. It will be apparent at once that if the village had waited until private enterprise furnished it with electric lights, it would have waited a very long time. The profits of the station at the very low price at which it furnishes light are too small to induce any one to undertake such an enterprise. On the other hand, if a private company had set up a station and offered current at rates materially higher than those now in force in Johnson, they would undoubtedly have had smaller net returns than those of the present station, for it must be constantly be borne in mind in the study of this case that most of those who are using the light in Johnson could not or would not afford it if its price were not so phenomenally low.

The corruption and incompetence with which municipal affairs are apt to be handled is an old story; but in the country towns of New England, where the "town-meeting" system of government still prevails, corruption or dishonesty in the management of town affairs is practically unheard of, and public matters are handled, as a rule, as intelligently and wisely as is the private business of the dwellers in the towns, which is of course all that can be expected.

The Johnson electric lighting plant was built and is managed by the trustees of the village corporation, elected annually at a village meeting and serving without compensation. The original trustees were Messrs. I. L. Pearl, O. B. Landon, C. H. Stearns, W. H. Nye and T. A. Riddle. At the last election Messrs. Enos Sherwin and B. A. Hunt succeeded Messrs. Pearl and Landon. Mr. Elmer Balch is the engineer of the power station; the writer is indebted to him and to members of the board of trustees for information used in the preparation of this article.

The reader who has carefully followed the above description will see that there are two principal reasons why electric light is furnished so cheaply at Johnson. First is the use of a water-power that costs when actually developed at the turbine shaft only about $32 per HP. The second is the construction and operation in the most simple and economical manner. The third is, we believe it is entirely fair to say, the owning and operation of the plant by the village, making it perfectly secure from competition and enabling the capital for construction to be secured at a low rate of interest, and also eliminating the element of speculation from the enterprise to a large extent.

It is because we have felt that there were some lessons in the experience with this Johnson plant which communities elsewhere might profit by, that we have given this much space to its description. There are still hundreds of country villages which, if they have not unused water-power at their doors, as had the village of which we have written, could develop water-power within a distance not so great as to make its cost prohibitory, and could thus have well-lit streets and homes in place of their present dependence on kerosene lamps.

There are other and larger communities whose water-power should be put to tenfold its present use in the distribution of electric light and power, and this will be done, when rates are lowered to a point which will encourage the extended use of electricity instead of being maintained at a point at which it is rightly regarded as a luxury.

Nor are we sure that the steam-operated electric stations have nothing to learn from the experience of the insignificant little village of which we have written. Production on a large scale is always cheaper than production on a limited scale. Other things being equal, electric light should be furnished in a city of 100,000 inhabitants more cheaply than in a village of 1,000. Is there not too great a disparity at present between the actual cost of steam power on the shaft of the engines in an electric lighting station and the cost of the same energy to the consumer when transformed to electric current and delivered at his house?

It is frequently urged that few electric lighting companies are paying good dividends, but may not this be due in many cases to the expenditures incurred for other things than legitimate and economical construction and operation?

We find manufacturing concerns installing electric lighting plants and lighting all their establishments at a trifling cost compared with other systems. We see street railway companies heating their cars by electric current although well aware that half or two-thirds as much current may be required to heat the car in cold weather as to propel it. All these things tend to show that when the business of manufacturing electrical current and transmitting it to consumers is conducted on an economical basis, it can be furnished at prices much below those now generally charged; and the large demand which will result when prices are lowered will very likely leave larger profits to owners than those that are now received.

THE CAPE COD CANAL CO., officially known as the Maritime Canal Co., has been authorized by the joint board of Railway and Harbor and Land Commissioners to issue "from time to time" the $6,000,000 stock and $6,000,000 bonds provided for in its charter.

LETTERS TO THE EDITOR.

Railway Construction in Japan.

Sir: The Sanyo Railway is the southernmost trunk line on the Hondo Island. We are just starting on the construction of 85 miles from Hiroshima to Mitashiri. After this piece is completed we have about 45 miles left from Mitashiri to Shimonoseki, which is the southern terminus of the line.

In all, Japan has now 2,350 miles of railway in operation, and the proposed lines, chartered and unchartered, amount in all to 12,000 miles. What percentage of these latter will be built, we, of course, do not know; but we conjecture that in 15 to 20 years Japan will have about 9,000 miles of railway, which would be about enough, as the geographical situation makes sea transportation very easy and economical.

While in America I thought American railway materials might be exported to Japan; but at present this seems well-nigh impossible. A few American rails have come; but at present it seems almost impossible to import them. Until a Central American canal is built the United States cannot export bulky goods to this country to any considerable extent.

Yours truly,
C. Kadono,
Assistant to Chief Engineer and Engineer of Construction,
Sanyo Ry. Co.
Hiroshima, Japan, Sept. 8, 1896.

The Conversion of Silver into Gold.

Sir: My attention has been called to your issue of Aug. 17 in which you quote some remarks from the "Engineering and Mining Journal" of Sept. 5 with reference to myself. Those remarks were fully replied to by me in the next number of that periodical; but as many of your readers may not have seen my answer I trust you will permit me to make, in your columns, the following statement respecting my attitude on the question of the transmutation of metals.

I assert, and am ready to prove, if challenged to do so, that many of the most eminent men of science of to-day, as well as of past times, regard the transmutation of metals as being possible.

I assert, but am NOT ready to prove, that the conversion of silver into gold is an accomplished fact. I do not make this assertion in the hope or expectation of its being believed by anybody, whether scientific or unscientific. If Lord Kelvin or M. Berthelot or Prof. Ira Remsen were to make the like assertion, unsupported by proof, I should not feel myself called upon to believe it. I should not, indeed, doubt the personal veracity of such eminent men, but I should hold myself at liberty to deem them mistaken.

All that I intend or really do in the premises is to enter what may be termed a public caveat. I am firmly convinced that the end of this present century will see the advent of a new school of chemistry and physics which shall teach the way to technical progress far surpassing what has been accomplished under the doctrines hitherto accepted. I am not alone in this conviction; it is shared by many of the leading chemists of the day. I therefore conceive it a matter of scientific duty on my part to boldly throw down the glove of priority at the feet of my fellow-investigators. I issue my challenge to the whole world of science. If anyone thinks himself my predecessor in the art of transmuting metals, let him make public his claim. I will meet him, claim for claim, and proof for proof. If none take up my gage, my claim to be the pioneer and leader of the new chemistry will at least remain undisputed, and must be universally conceded whenever I may think proper to reveal its foundation of fact.

Stephen H. Emmens.
1 Broadway, New York, Oct. 1, 1896.

(In view of the present political situation, we cannot refrain from expressing regret that Mr. Emmens is not ready to prove at the present time that silver can be converted into gold.—Ed.)

Nicaragua Canal and Earthwork Slopes in the Tropics.

Sir: In the issue of your paper of Aug. 13 I find two letters which refer to a letter of mine published in your issue of the 25th June.

The letter of Mr. J. T. Ford shows the necessity for further surveys on the Atlantic slope of the Nicaragua Canal, but Mr. Ford seems to infer that there is no such necessity on the Pacific slope, and, furthermore, thinks that I am not familiar with the ground near the Pacific terminus. Now, it is because I am familiar with the ground, and have been in Salinas Bay (although not over the line I propose), that I believe a survey should be made from the Lake to this port. I will admit that the cost of the canal itself, between the Lake and Salinas Bay, will be somewhat larger than that of the present line, but I believe that a proper survey of this route will demonstrate that the cost of the canal would not greatly exceed the cost of the present location plus the cost of making a suitable port at Brito, nor would the Salinas Bay line be much, if any, longer than the present location of the canal. As far as I am aware no survey has ever been made of the Salinas Bay line, and one should certainly be made of this route before the final location is decided.

I do not know enough of the Colorado outlet as it is at present to confirm Mr. Ford's projected port at that place, but believe that proper surveys should be made to demonstrate whether it is practicable and better than the Greytown one or not. The whole Nicaragua Canal project requires more complete, more thorough and more extensive surveys before any further work be done thereon, and everyone interested in the successful conclusion of the canal should continue to din this into the ears of Congress until they appropriate a sum sufficient for these complete surveys.

With regard to the letter of Mr. Charles Thornton, if he had carefully perused mine of May 9, he would see that I referred particularly to the slopes of the cuts on the railway, and this in view of the report of the Commission. I certainly did not intend to intimate that any such slopes as one-half to one should be used in the canal excavation, although I fail to see why steep slopes should not be used above water line where the nature of the soil will admit, nor did I intend it to be inferred that embankments would stand at that slope. Mr. Thornton also says: "All of nature's laws are in full force in the tropics as elsewhere," to which I take exception, for, as I stated before, we have no frosts to contend with here, and everyone who has had experience in excavations in the temperate zone knows that frosts in that climate is a great disintegrator and destroyer of slopes of excavations.

Respectfully,
Silvanus Miller, M. Am. Soc. C. E.
Puerto Barrios, Guatemala, Sept. 18, 1896.

(Salinas Bay is about 20 miles due south of the point where the present location of the canal strikes the west shore of Lake Nicaragua. It is on the boundary line betwen Nicaragua and Costa Rica.—Ed.)

◆

THE PRESENT STATUS OF THE DISTRIBUTION AND TRANSMISSION OF ELECTRICAL ENERGY.

(Concluded from Page 231.)

parently laid on the question of the reliability of the power. If the industries of a large city depended upon a single transmission plant, it is evident that the question of reliability is of paramount importance. Where energy is supplied to manufacturers, the street car systems, and for lighting, a break-down that would involve the cutting off of current for a day would mean an enormous pecuniary loss to the community. As the distance of transmission increases, the possibility of accident is increased in greater ratio because we have not only the higher voltages to control but the length of the line that must be looked out for is also increased. The best guide lies in the practical experience which has been obtained in the present transmission plants and the consideration of the difficulties that have arisen and the remedies that have been employed. I have prepared a partial list of the principal transmission plants that are now in operation.

It will be seen that the longest transmission is at Fresno, Cal., the distance being about 35 miles. The highest alternating voltage used is 13,000 volts at Zurich, Switzerland. The highest direct potential is 15,000 volts at Brescia.

All of these plants are working successfully, and this fact will lead to still longer transmission and higher voltages. No limit of either distance or potential has as yet been reached. It we consider the record of the present transmission plants, we can safely say that it would not be going outside of the safe limit of development to transmit at least 50 miles at a potential of 20,000 volts, provided the energy could be delivered at such a price as to be considerably lower than the cost of a corresponding amount of energy obtained from a steam plant. This, of course, is a matter of local condition entirely, and the commercial value of such a transmission will depend upon local conditions.

Long-Distance Transmission for Railway Work.

The possibility of long-distance electric railway lines is intimately connected with the possibility of long-distance transmission of power. We have seen that it is possible to transmit considerable distances from a single station. The current so distributed is not, however, such that it can be applied directly to railway motors, but it must be transformed at points along the line, the distance apart of these points of distribution depending upon the system that is employed. At present continuous current motors are used and considerations of safety would lead us to use line potentials not greater that 700 volts. By distributing rotary transformers at distances of five or six miles apart, we would be able to supply motors with current without any great investment in copper. The amount of copper required could still be further reduced by using rotary transformers with storage batteries, thus keeping a constant load on the transmission line. It will be found, however, that on any long-distance railroad line, the load on any section of the line is exceedingly variable and the discharge rate of the batteries will have to be very high in order to prevent excessive cost for our reducing stations. It is doubtful whether we have reached a point in battery construction that this system of transmission would be economical. It is certain, however, that when the distances are comparatively short, say, within 15 miles, and where the traffic is not evenly distributed, that rotary transformers, with or without batteries, can be economically employed for railway work.

Conclusion.

My conclusions, subject always to the influence of local conditions, are as follows:

1. In both direct-current lighting and traction systems, where the power is generated in or near the area of distribution, it is best to use one station situated at the most economical point for producing power.
2. In the case of the traction systems, when the economical area of direct distribution is passed, boosters should be employed directly or in connection with batteries, to a distance of ten or twelve miles from a station, and beyond this rotary transformers, whether with or without batteries, should be used.
3. In the case of direct-current lighting systems, the energy should be transmitted to storage batteries situated at centers of consumption either directly or by means of a rotary transformer and distributed from them.
4. Where batteries are used it is best to place them at the end of feeder wires to obtain the advantage of a constant load on the wire.
5. The best system for the long-distance transmission of energy, for general purposes, is the three-phase alternating system.
6. Commercial transmissions are in successful operation for distances of 35 miles, and for voltages as high as 15,000 volts.

Experience with these plants shows that the transmission of 50 miles with a pressure of 20,000 volts is practicable, beyond these limits the transmission would be more or less experimental.

THE NATIONAL BALL NOZZLE CO. is being sued, at Trenton, N. J., by the Columbia Hose Nozzle and the American Nozzle companies for an infringement of patent. The defendant answers that the essential and substantial features on which the patents are based were known, among others, to "One Herod, now deceased, but formerly of Alexandria, Egypt, living at said Alexandria and elsewhere 1,000 B. C."

◆

A TAR FILLER FOR SOME OF THE JOINTS IN BRICK pavements has been used at Cortland, N. Y., in place of Portland cement, which was used for the main part of the work. The specifications for this work were written by Mr. Wm. B. Landreth, M. Am. Soc. C. E., who, at the suggestion of Mr. F. W. Dalrymple, Assoc. M. Am. Soc. C. E., City Engineer of Hornellsville, N. Y., called for a strip of the paving three joints wide along the crown of the street, and across the street every 100 ft., to be filled with common tar paving filler, to allow for a movement of the pavement, caused by the heat or the expansion of the cement in setting. One block of the pavement, 600 ft. long and 29 ft. wide, has been completed as above specified, the cement joints being filled with a high grade of American Portland cement. In three days after the joints had been filled the expansion began to force the tar filler from the joints, although the temperature had varied but little and at no time had exceeded 65° F.

The expansion seems to have been caused by the expansion of the cement in setting, although the cement was carefully tested for expansion before using. Since the cement became set hard the expansion seems to have ceased.

◆

OLD BRICK ARE BEING USED instead of sand to make lime mortar, in the rebuilding of the new Union Station in Columbus, O. The refuse brick from the old walls are ground in a crusher. It is said that a quality of mortar for color work superior to that obtained with sand is produced.

◆

A GREAT PLATE GIRDER, 54 ft. 6 ins. long, 6 ft. deep and 24 ft. wide, was hauled on a truck to one of the new buildings in Nassau St. The weight is said to have been about 32 tons, and 20 horses were required to haul it. It was built by the New Jersey Steel & Iron Co., of Trenton, N. J.

◆

THE LOVE CONDUIT SYSTEM of electric street railways is to be installed on a quite extensive scale in Chicago, according to recent reports. The General Electric Ry. Co. of that city obtained some months ago a franchise for about 18 miles of line on the south side of the river, and it is upon this line that the conduit system is reported as to be used. According to the published statements of the General Electric Ry. Co., the work of construction is to begin at an early date, and besides this line, for which a franchise has already been secured, some 20 miles additional are to be built. The down-town terminus of the line will be at Jackson St. and will extend south as far as 57th St. The Love Traction Co. is reported to be the controlling interest in the scheme, but so little regarding the company's plans has been made public that it is impossible to give any definite statements regarding the prospects for construction.

GARBAGE UTILIZATION AT CINCINNATI AND NEW ORLEANS.

Of the 16 cities in the United States having populations of over 200,000 in 1890, there have already been established in ten cities, or soon will be, some improved system of garbage disposal. The 16 largest cities of the United States, in order of population, with the system of garbage disposal adopted, if any, are as follows:

City.	Population, 1890.	System.
New York	1,515,301	Utilization.
Chicago	1,099,850	None.
Philadelphia	1,046,964	Utilization and cremation
Brooklyn	806,343	None.
St. Louis	451,770	Utilization.
Boston	448,477	None.
Baltimore	434,439	None.
San Francisco	298,997	None.
Cincinnati	296,908	Utilization.
Cleveland	261,353	None.
Buffalo	255,664	Utilization.
New Orleans	242,039	Utilization.
Pittsburg	238,617	Utilization.
Washington	230,392	Cremation.
Detroit	205,876	Utilization.
Milwaukee	204,468	Utilization.

It is the purpose of this article to describe the utilization plants at Cincinnati and New Orleans, built under the Simonin system.*

The Simonin Process.

Before describing these two plants some information may be given regarding the Simonin system, though the details of this will be best understood by referring to the description of the Cincinnati plant, below, where the progress of the garbage during the whole process is described, as seen on the spot by our representative.

The patent on the Simonin system was issued on Jan. 5, 1892, to Chas. F. and Isaac M. Simonin, as No. 466,579, and is still controlled by these gentlemen, who have offices at Trenton Ave. and Clearfield St., Philadelphia, under the name of Simonin & Simonin. Regarding the development of the process and the plant at Providence, which latter has given rise to some misconception, Simonin & Simonin have given us the following information:

> This process was developed at Providence, in the works built by private parties to utilize the garbage of that city, by the Simonin & Adamson process. -This latter process not proving a financial success was discontinued. No city contract ever existed at Providence, but the garbage was delivered at the experimental plant by the garbage contractor.

The patent specification mentioned above describes a process for the removal of grease from garbage containing water, and the claims are for the combination by which this is effected, including the use of a heated liquid reagent, solvent to grease and of less specific gravity than water; the separation of the grease and water and the recovery of the reagent, together with the certain extractors, settlers, stills, cooling coils and means of connecting the same. The broad method of the extraction of fatty matters by means of benzine, naptha or other volatile reagents of low specific gravity is not claimed, this having "long been known and practiced."

The plant at New Orleans has been shut down for some months past, but the causes for this seem to be local, so we do not on that account refrain from making use of the detailed information so kindly furnished us, as acknowledged below, regarding the character and extent of the works. Both the New Orleans and Cincinnati plants have been visited by a member of our editorial staff, but circumstances were such that our representative could see and learn more of the workings of the Cincinnati than of the New Orleans plant, so it will be described first.

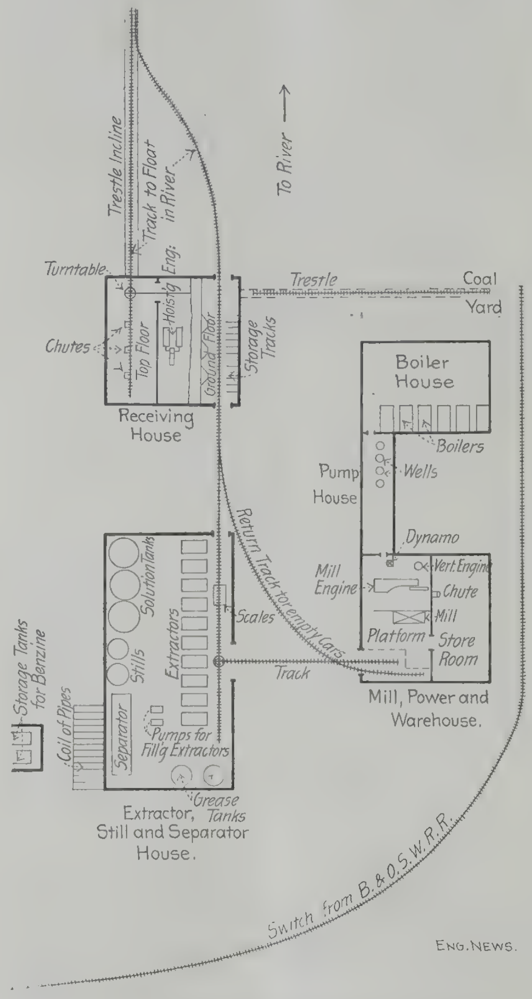
The Plant of the Sanitary Extracting Co. for the Treatment of the Garbage of Cincinnati.

We learn from Simonin & Simonin that the garbage of Cincinnati is treated under a contract running for ten years from June, 1892, the compensation being $15,000 for the first, $17,000 for the second, $19,000 for the third, $21,000 for the fourth, and then increasing $1,000 a year to $27,000 for the tenth year.

The following further information regarding the Cincinnati plant was obtained by our representative on a visit to Cincinnati, Dec. 24, 1895:

The garbage of the city of Cincinnati, O., is disposed of by the Sanitary Extracting Co., of that city. The president of the company is Senator J. B. Foraker and the secretary is Mr. E. F. Smith, both of Cincinnati.

The reduction plant of the Sanitary Extracting Co. is located near Riverside, a suburb, and about six miles from the business district of the city. The district is only sparsely built up and there are no houses within probably one-half mile of the works. The character of the dwellings indicates that the owners or occupants are people of very moderate means and in many cases (as indicated by the premises) not such as would be troubled by more than ordinary unsanitary conditions. It is said that complaints have never been made by these householders of any nuisance on account of the disposal works.



Sketch Plan of Garbage Disposal Plant at Cincinnati, O.

The plant occupies a tract of about five acres of ground lying between the north bank of the Ohio River and the tracks of the Baltimore & Ohio Southwestern R. R., and about 300 ft. distant from both the river and the railway. This ground is fenced in and no admittance is allowed except to employers and people on business. A written order is necessary to secure entrance. From the railway line a switch track enters the grounds. By means of this switch the works receive coal (at times) and other supplies, and ship away the grease and fertilizer. The grease is shipped away in tank cars supplied by the Standard Oil Co. Two tank cars were on the switch track on the day of the visit.

The accompanying illustration is a rough sketch plan of the works, which include a receiving house, extractor, still and separator house, mill, power and warehouse, pump house and boiler house. The sketch is not drawn to a scale.

The garbage is collected by the city and loaded into scows furnished by the company. Ordinary rectangular flat-bottomed wooden scows are furnished. When a scow is full, and not before, it is towed to the works. In summer about one scow is filled per day. At the time of the writer's visit about one scow per week was filled. The scows are furnished and the towing done by a local company under contract with the garbage company. The scows are anchored at a float in the river, and unloaded by hand into steel cars, of about 2,500 lbs. capacity, hopper-shaped, opening at bottom, of 4-ft. gage. During this loading of the cars all tin cans, etc., are separated from the garbage and left temporarily on the float. Afterwards the tin cans are taken from the float and dumped in a waste pile on the river bank. No use is made of tin cans. From the float a 4-ft. gage track runs up a trestle incline to the top floor of the receiving house. This track straddles the openings to the chutes leading from the top floor to the ground floor. The hoisting is done by a stationary engine and cable. There are three chutes, and four cars are used.

The hoisting engines for hauling the cars from the float to the receiving room are placed parallel and operate a single horizontal engine shaft which carries a pinion at its center. This pinion meshes with a spur keyed to a shaft on which the drums are mounted. These engines are a pair of 8 × 16-in. link motion reversing engines, from the I. & E. Greenwald Co., of Cincinnati. When possible, i. e., in summer, coal is received by scows unloaded at the float into the garbage cars, hauled to the turntable at the upper end of the incline, run onto the trestle and dumped into the coal yard. At other times it is received by the switch track. The garbage chutes discharge at the ground floor, this discharge being controlled by the necessary doors. A track on the ground floor runs directly under the discharge openings. In the Simonin process the garbage is loaded into a number of shallow pans perforated with numerous openings. A set or column of these pans is made by setting one on top of another, and the set or column carried on a metal truck. The truck, pans and all is run into the extractors. A tram car, with rails on top, runs on the track extending along the lower floor of the receiving, and to and into the extracting house. On this tram car is set the pan car. The pan cars with empty pans are stored on the storage tracks at one side of the main track in the receiving house, as shown in the sketch plan. A tram car is run onto the main track and stopped directly under a chute opening. A pan car is then run onto the tram car and blocked. The bottom pan is placed and filled; then the second pan is placed on top of the bottom pan and filled, then the third pan placed on top of the second pan and filled and so on until a "set" of pans is filled. The tram car is then run along the track to an empty extractor in the next building, and the pan car run off the tram car into the extractor, after being weighed on the scales. The head is then bolted onto the extractor and the process of extraction begun. The lids of the extractor, which are of cast iron, and very heavy, are handled by an overhead trolley.

As will be seen from the sketch plan, there are ten extractors; each is a 6 × 22-ft. cylinder, standing horizontally. When the car load of garbage has been fastened into an extractor, benzine is forced into the extractor until it is filled, by means of one of the pumps near by. After the benzine has taken up all the grease the solution of grease, benzine and water is forced into the three solution tanks. The solution then passes into the two adjoining stills, where the benzine and water are vaporized and sent into the coil of pipes, shown just outside the building. A constant cascade of cold water flows over the pipes, thus condensing both the steam and benzine vapor, which flow as liquids into the separator. The benzine is then taken off the water and conveyed to the storage tanks, shown in the separate building near by. The grease which remains in the stills is passed into one of the two storage tanks, in a corner of the building, where it is ready for shipment. Only one storage tank is used at a time, the other being held in reserve.

Meanwhile the solid matter in the pans in the extractor has been thoroughly dried by the steam heat. The head is taken off the extractor and the car, with its set of pans filled with dry "tankage," is hauled out, weighed and run onto a tram car and the tram car run along a track to the mill room. Each pan is dumped onto a platform in front of the mill. As each pan is dumped it is placed on a pan car, which is placed in turn on a tram car standing on an adjoining track. By this process the top pan of the first carload becomes the bottom pan of the second carload of "empties," which latter are sent back to the storage tracks.

---

*Of the ten utilization plants included in the above list, those at St. Louis, Buffalo, Detroit and Milwaukee employ the Merz process, and were described at length in our issue of Nov. 1, 1894. At Pittsburg, the system controlled by the Consolidated American Reduction Co., and described in our issue of Oct. 3, 1895, was installed. The plant at New York will employ the Arnold process, which, as temporarily used in Boston, was described in Engineering News of March 28, 1895.

From the platform the tankage is shoveled into the mill and ground. A continuous bucket elevator takes the ground matter and conveys it to the second story, where it is dumped onto a sieve. The material passing the sieve falls into a chute which opens into the storage room. The bags are hung under a spout and filled. They are then stored for shipment.

The power room contains the engine for operating the mill and a vertical engine for operating an electric light dynamo. The mill engine is a 12 × 30-in.cylinder, automatic cut off, trip valve engine of the Brown type, and was furnished by the I. & E. Greenwald Co., of Cincinnati. Between the mill and boiler houses is the pump house, beneath which four wells, 100 ft. deep, supply the water. The water is pumped by four Laidlaw-Dunn-Gordon standard No. 4,040 deep well pumps. The water is forced onto the coil of pipes and then runs into an earth reservoir. The overflow from this reservoir drains along the surface of the ground to the river.

The boiler room contains six 16 × 5½ ft., 54 4-in. tubular boilers built by McIlvane & Speigel, of Cincinnati, O. Steam pipes run to the various engines and to the extractors, stills, etc., in the extractor house.

The extractor house is built of brick, but the other buildings are of wood, covered with corrugated iron. There are 46 "sets" of pans used altogether. About 24 men are employed at the works in the winter, and during the summer months four or five additional men are employed in unloading the garbage and other rough labor. No exhaust fans are used anywhere about the building. The plant is operated continuously as long as there is garbage.

Garbage Collection at Cincinnati.

The following information regarding the collection of garbage in Cincinnati was obtained from Mr. Fred. Amthauer, Superintendent of the Street Cleaning Department:

The garbage of the city of Cincinnati, O., is collected by the street cleaning department and expenses are paid from the general fund appropriated for street cleaning. Garbage collection in that city is thus a part of the work of cleaning the streets, and no especial provision is made for doing it. In collecting, the ordinary tight board wagons used for collecting ashes are used, the garbage being covered simply with a tarpaulin. The wagons are used interchangeably for collecting garbage and ashes. For example, a wagon may work half a day hauling garbage and the other half day hauling ashes. One day two wagons will haul garbage to every one which hauls ashes, while on the next day the exact contrary disposition of the wagons will be made, two wagons ashes to one wagon garbage. In winter, when the garbage can stand longer without offense and the snow and mud is the worst, street cleaning is placed first and garbage collection second. In summer the garbage is collected first and the streets cleaned second.

In the most populous districts garbage is collected daily during the summer. Elsewhere the collections are made every second or third day, as the conditions seem to demand. In winter collections are made less often everywhere. In other words, the superintendent of street cleaning uses his discretion in making the collections more or less frequent, the only point observed being to keep the garbage receptacles clean and inoffensive. It is intended always to keep the garbage inoffensive even at the expense of dirty streets.

Ashes are forbidden to be mixed with the garbage proper, but no reservation is made as to the inclusion of tin cans, bottles, etc. Of course, householders occasionally mix their ashes and garbage, and then the drivers refuse to take the mixture. Generally warning from the health officer is enough to stop the trouble, but occasionally fine and arrest is necessary.

It is realized that the education of the householders is as much the duty of the health officer as fines and arrests, and care is taken to instruct them not to mix garbage and ashes. The drivers of the collecting wagons and sanitary inspectors are instructed to warn careless persons and new householders. In addition, thousands of circular sheets of instruction are distributed annually.

No special receptacle is required to be provided by the householder and consequently a great variety of forms are used. The superintendent of street cleaning makes complaint of this, and says the work of collection would be lightened by having a common size and form of receptacle.

The garbage is all hauled to a scow provided by the Sanitary Extracting Co. and unloaded, after which the street department has nothing further to do with it. At this scow most of the tin sans, bottles, etc., are taken by junk men who seem willing to separate them from the garbage for what they can make from the salvage. A few cans and bottles, of course, remain and these are separated at the garbage plant.

From the big hotels the garbage is collected by the Sanitary Extracting Co., which has one wagon for that purpose. This is the only garbage collected by the company and which the street cleaning department does not collect. (Dead animals not included.)

Dead animals are removed without expense to the city by the Jones Fertilizing Co., which gets its compensation from the hides, grease, manure, etc. The Sanitary Extracting Co. does not handle dead animals at all. The Jones Fertilizing Co. is supposed to collect all animals, but the city wagons usually take in small animals whenever they come across them.

After unloading each wagon at the garbage scow it is flushed out with a few bucketsful of water, and before going into the stable at night it is washed with a hose and sprayed with a solution of copperas and water. The scow stands at its dock until it is filled.

A record of the loads of garbage hauled to the scow is kept, but no record of weight. As a matter of curiosity the garbage was weighed for a day or two and it was found that the loads weighed from 1,900 lbs. to 3,200 lbs. and averaged about 2,500 lbs. During the year 1894, 13,894 loads of garbage were hauled to the scow, which on the basis of the above average would be 17,368 tons. A daily record of the number of loads hauled during the month of August, 1894, is appended as follows:

Day.	Loads.	Day.	Loads.	Day.	Loads.	Day.	Loads.
1	41	10	77	18	3	26	78
2	99	11	3	19	101	27	92
3	71	12	98	20	78	28	75
4	3	13	85	21	57	29	48
5	90	14	58	22	52	30	92
6	90	15	49	23	89	31	81
7	57	16	92	24	80		
8	52	17	80	25	3	Total.	2,053
9	79						

At an average of 2,500 lbs. per load the amount of garbage collected in August would be 2,560 tons.

Dr. J. W. Prendergast, Health Officer, says that the disposal of garbage by the Sanitary Extracting Co. has caused no nuisance and is sanitary.

The Contract and Works of the Southern Chemical & Fertilizing Co. at New Orleans.

On March 15, 1894, a contract went into effect between the Southern Chemical & Fertilizing Co. and the City of New Orleans for the collection and disposal of the garbage, dead animals, ashes, street sweepings and general house and store refuse of the city, for a term of 20 years. The contract, we are informed, was based on an ordinance directing the comptroller to call for bids for this work and containing specifications for it. This ordinance provided that no contract should be closed

> until the successful bidder has presented a system of disposing of refuse vegetable and animal matter, including dead animals, in a manner which is scientific and sanitary, disposing of whatever is injurious to health and discomforting to the human race, at the same time preserving whatever is valuable in the material aforesaid.

Another part of the ordinance required the erection of a cremation or utilization plant.

The ordinance also provided that the means and methods provided and employed in collecting and treating the garbage should be satisfactory to the State Board of Health of Louisiana.

Garbage and dead animals were to be collected daily; street sweepings when the department of public works should direct, the latter to be gathered into piles by the department.

One section of the ordinance defined garbage and prohibited its mixing by house-holders with other matter, as follows:

> Sec. 4. Be it further ordained, etc., that the word "garbage" as used in this ordinance shall be construed to mean house and kitchen offal, and all refuse matter not excremental, whether solid or liquid, and composed of animal and vegetable substances, including dead animals coming from public or private premises of the city, and not destined for consumption as food. No ashes, dirt or other substances foreign to garbage shall be covered by this contract, except as hereinafter provided, and it shall be unlawful for any occupant or occupants of any premises in the city of New Orleans, to mix any such ashes, dirt, or other substance foreign to garbage, with the garbage to be removed from said premises as herein provided, under a penalty of not less than $5, nor more than $25 fine for each offense, or imprisonment for not more than 30 days.

Householders were required to deposit their garbage in covered metallic vessels and the contractor was required to use "inclosed, water-tight metallic vehicles" for removing the garbage.

The garbage wagon afterwards adopted by the contractor was illustrated and described in our issue of May 17, 1894.

The contract price for performing the services outlined above was $120,000 a year for the first five years, $134,000 for the second, $150,000 for the third, and $165,000 a year for the fourth five years. This amounted to a total of $2,845,000, or an average of $142,250 per year.

The company selected the Simonin process for the treatment of the garbage and erected an extensive plant. The following description of the plant has been prepared from information furnished us under date of Feb. 11, 1896, by Mr. T. A. Clayton, who was at that time General Superintendent of the Southern Chemical & Fertilizing Co.

The company began work on July 11, 1894, and has continued its collections since that time, but the disposal works have been shut down since Nov. 20, 1895, "partly on account of the low prices obtainable for the product, but chiefly on account of the difficulty in getting the citizens to refrain from mixing their garbage with ashes and other foreign matter." During the construction of the plant Simonin & Simonin were represented by Mr. W. H. Hughes, of Providence, R. I. Mr. Clayton states that many improvements have since been made. The plant has a guaranteed daily capacity of 75 tons of drained or about 100 to 125 tons of wet garbage.

The disposal works are located seven blocks from Canal St. and 34 blocks from the river. A switch runs into the works from the Mississippi Valley R. R. The New Basin Canal, which runs from the heart of the city into Lake Pontchartrain, is about 120 ft. distant.

Eight buildings house the plant, their character and uses being as follows: A pocket house for the reception of garbage and a rendering house for the treatment of dead animals, in one building 60 × 100 ft., 40 ft. to the ridge; brick, with slate roof. Attached to this is an inclined run for the garbage and dead animal wagons to get up to discharge their loads. This run is inclosed, covered with galvanized iron, and the lower part is used for a stable. An extractor room, 75 × 100 ft., 40 ft. to the ridge; of brick covered with slate, in which are contained the extractors, stills, solution and grease tanks. A brick building, slate covered, 60 × 183 ft. and 35 ft. in height to the ridge, of which 62 ft. contain the boiler and engine room, 35 ft. the mill room, 40 ft. a warehouse, and 46 ft. another warehouse, all divided by fire walls. A brick building covered with galvanized iron, 50 × 100 ft. used as a stable. A frame building, inclosed and covered with corrugated iron, 37 × 50 ft., two stories, with the lower story used as a blacksmith shop, etc., the upper story a machine shop, and having attached a cupola for melting tin cans and old metal of all sorts. A corrugated iron building, 30 × 65 ft., by 30 ft. high, inclosing a crematory for the destruction of garbage, etc. A frame building, 23 × 31 ft., containing the naphtha tanks, and a brick slate covered office 25 × 32 ft.

The steam plant consists of six 150-HP. horizontal tubular boilers. There are four engines. Of these, a 75-HP. Greenwald engine drives the grinding mill; a 15-HP. New York Safety runs the electric plant; a 10-HP. Racine engine drives an 18-in. exhaust fan used in connection with the rendering tanks for treating the dead animals; and a 15-HP. engine is provided for the cupola blast and for driving the machinery in the machine shop.

Two 12 × 10½ × 12-in. pumps are used to pump water over the condensing coils; a 7½ × 4½ × 10-in. pump is used for boiler feed; and two, 6 × 6 × 12-in. pumps for lifting the naphtha into the extractors. All these are Blake pumps. The water supply is from a 730-ft. artesian well and the canal. The utilization plant requires the use of 800,000 to 900,000 gallons daily, but when cremating the garbage only a few thousand gallons a day are consumed. From this statement it might be inferred that the garbage is burned when not treated by the utilization process.

There are two iron smoke stacks, one 52 ins. in diameter and the other 60 ins., each 80 ft. high, the top of one being 104 and the other 102 ft. above the ground.

The nine extractors are 6 ft. in diameter and 22 ft. long, and were made by McIlvain & Spiegel, of Cincinnati. The extractors are so connected that the steam and naphtha can be passed from one to another, if desired, thus economizing steam and saving the work to be done by the condensing coils. The stills for separating the naphtha and grease are two in number, each 6 × 15 ft. Steam coils run through these stills.

The tankage is ground, so far as necessary, by a 4-ft. Luttner cage mill with a daily capacity of 12 to 15 tons, according to the quality of the material.

When the plant is in operation about 20 unskilled laborers are employed at $1.50 a day; two firemen at $2 a day; and three skilled laborers at $2.50 a day. The plant is operated night and day and from November, 1894, to October, 1895, 14,300 tons of drained garbage was treated, to which 40% must be added, Mr. Clayton states, to get the weight of the equivalent amount of green garbage. The daily record of drained garbage treated in June, 1895, is as follows:

June	Lbs.	June	Lbs.	June	Lbs.
1	59,178	12	60,730	23	46,810
2	43,900	13	67,930	24	60,990
3	61,264	14	60,020	25	38,128
4	24,490	15	68,380	26	68,614
5	99,480	16	38,070	27	63,360
6	73,184	17	66,450	28	63,708

The amount of grease derived from the garbage is given as 5 to 7%, and of tankage for fertilizing purposes, 25 to 30%, both by weight. The only material taken to the works which cannot be reduced is paper, rags, feathers and similar wastes, which, being very dry, are burned under the boilers. The waste liquids are run into the sewer.

The following information regarding the New Orleans plant was obtained by a member of the editorial staff of this journal during a visit to the plant in the fall of 1895:

The statement made by Mr. Clayton regarding the location of the plant may give the impression that the plant is not far from the thickly settled part of the city. Such is not the case. Canal St. extends north, slightly west from the river front, toward Lake Pontchartrain, and while a principal street its northern end penetrates a sparsely settled and poor quarter of the city. The houses are 1 and 1½ story frame structures and seem to be inhabited chiefly by negroes.

The most unsanitary things seen about the works were a dozen or so empty and uncleaned iron collecting wagons. Inclosed by a fence were the buildings of the plant, much the handsomest and best constructed buildings of any plant seen by our representative, except, possibly, those at St. Louis. Much of the area between buildings was paved with concrete or cement, and except where piles of dry refuse from the extractors temporarily existed until used in a further process, this pavement was very clean and dry. Inside the buildings there was the usual sour smell of green garbage and the odor of fertilizer, but only where the dead animals were handled were things very offensive, and then only in the building itself. A smelling excursion around the building did not impress one with the idea of there being any nuisance, and the day was hot and a slight breeze blowing. In point of odor this plant may be placed ahead of that at Cincinnati.

The impression received regarding the crematories was that they were used to handle garbage of very little value for extraction or otherwise unfit for the process by the admixture of ashes.

Since our representative visited the plant and since Mr. Clayton gave us the information quoted above the city has attempted to annul the contract with the company on the ground of non-fulfilment. After this action a receiver, Mr. Algernon A. Badgley, was appointed and he has appealed to the Federal Court to enforce the payment of the monthly sums stipulated in the contract and to prevent collection of garbage by the city. The following statement regarding the controversy has been prepared for us by Dr. Quitman Kohnke, chairman of the public health committee of the city council:

> The fight between the city and the garbage company (The Southern Chemical & Fertilizing Co.) need not reflect upon the efficacy of the "Simonin process" to dispose of garbage, but was brought about by violation of the sanitary laws on the part of the garbage company. It is charged that the company established dumping grounds within the city limits, some of these being on public thoroughfares where the collected garbage was deposited contrary to law and contract, and in violation of ordinary rules of health. It is claimed by the company that such disposition of garbage was made necessary by reason of the failure on the part of the householder to separate the garbage proper from the ashes and trash. On the other hand, it is claimed by the city that the company encouraged and assisted in the mixing of garbage and trash and deposited on the various dumping grounds pure garbage unmixed with ashes or trash—the real reason for dumping being that the increased price of naphtha and the decreased value of the products of the plant rendered it unprofitable to treat the collected refuse in the manner originally contemplated.
>
> Whether the company is released from its obligation to collect and dispose of garbage by reason of non-compliance on the part of the householder with that part of the contract providing for the separation of garbage from trash, will be decided by the courts. The position of the city appears to be that the company is obligated to remove and dispose of all garbage, mixed or unmixed, inasmuch as all others are expressly forbidden to remove it, it being incumbent upon the company to invoke the law against the householder who does not separate his garbage. A general complaint has been made by the company, but in no case has an individual householder been charged with violation of the law. This failure on the part of the company to prosecute the householder is supposed to have been due to fear that the law would be declared unconstitutional which compelled a citizen to perform without compensation a menial service for the benefit of a private corporation.
>
> The position of the Board of Health in this matter is that it recognizes no contract, but insists upon the prompt collection of all garbage and the suppression of dumping grounds for such refuse.

Under date of Sept. 28, 1896, Mr. Clayton wrote us further regarding the status of garbage disposal in New Orleans, as follows:

> It is a fact that when we are not using the reduction process we cremate the garbage in crematories that give perfect satisfaction in every way, and which I believe are the best and most economical in operation. These crematories are of our own design and construction, and are unique.
>
> With regard to the actual situation here in connection with the present status of the garbage disposal, I would say that our company is still collecting the unmixed garbage that is exposed by the citizens, transferring it to the plant and cremating it. The mixed garbage is being collected to a certain extent by the city. The authorities have refused to enforce the law which governs our contract with regard to the due obligation of house-holders to keep their garbage separate from foreign material, and are attempting to declare our contract null and void. The matter has been taken into the United States Courts through the appointment of a receiver, named at the request of some of the bondholders who live outside this state, and the case will come up in November, when we are confident of winning the suit.
>
> The city has gone back to the old system of sending garbage down the river and dumping it below the city limits, but their system is poorly organized, and is evidently of a temporary character.

From all we can learn on the subject, including reports of discussions in and out of the city council and statements by representatives of the company, it appears that the people of New Orleans awoke, after it was too late, to a realizing sense that Sec. 4 of the ordinance, quoted above, requires the separation of garbage from ashes and other refuse and rebelled against it. The requirement is a perfectly reasonable one, is a part of the contract, and essential to the successful operation of the plant required by the contract.

Whether it rests with the city officials or the garbage company to compel householders to separate the garbage, or whether the refusal of the company to collect mixed garbage is the proper course for it to pursue to secure its rights are questions now before the court.

In so far as the questions involved have any bearing upon the Simonin system of garbage disposal they apply equally to all other reduction or utilization systems in successful operation and must also be considered in connection with cremation, or even dumping at sea. We have discussed this matter further in our editorial columns.

THE INTERSTATE COMMERCE COMMISSION'S STATISTICS OF THE RAILWAYS OF THE UNITED STATES FOR THE YEAR ENDING JUNE 30, 1895.

An advance abstract of this report, as furnished by Prof. Henry C. Adams, the statistician of the Interstate Commerce Commission, was published in our issue of July 30; but from the full report, advance proofs of which have just been issued, much other interesting information can be gleaned relating to the status of the railways of the country up to the date of the report. The summary of mileage, equipment, classification, capitalization, earnings and expenses was given in the statement already published, but some of these will be repeated here in going into the details of the full report.

This report differs from its predecessors in not only making comparisons with the previous year, but in including, as far as possible, the years 1890 to 1894 inclusive. These six years, including 1895, cover a period of unusual commercial conditions, and the broader comparative statement is useful in any attempt to investigate and better understand the influences at work and their effect upon railways.

The Commission places the aggregate mileage of railways in the United States, on June 30, 1895, at 180,657, an increase during the year of only 1,949 miles, or 1.09%, which is less than the 1.27% of increase of 1894, the lowest in any year since the Commission was organized. In figuring out the miles of line per 100 square miles of territory for the whole United States there is, of course, a steady but slow increase, from 5.51 miles in 1890 to 6.08 miles in 1895. But population has been gaining upon railway construction in the same period, as is shown by the fact that in 1890 there were 26.05 miles of line to every 10,000 inhabitants, with a maximum of 26.51 miles in 1893 and a present ratio of 26.16 miles per 10,000 inhabitants. The report does not assume from this that there is any tendency towards a permanent change in commercial forces, and contends that until there is a more even distribution of railway facilities than there is at present, railways must still remain as the pioneers in industrial development. In looking over the summary of railway mileage for each state and territory there is still natually a wide diversity of percentage as effected by geographical position, age, density of population and facilities for producing goods for transport. Under the head of miles of line per 100 square miles of territory and omitting the small District of Columbia with 47.62 miles, we find New Jersey in the lead with 29.72 miles; closely followed by Massachusetts with 26.35 miles; Pennsylvania, Ohio, Connecticut and Illinois come next, with 21.67, 21.13, 20.81 and 19.02 miles respectively. The State of Nevada has only 0.83 miles per 100 square miles of territory; Oklahoma has 0.98 miles; Wyoming, 1.21 miles; Arizona, 1.22 miles, and Idaho, 1.29 miles. But these new and thinly settled states and territories, of course, rank highest in the ratio of miles of railway to 10,000 inhabitants; Arizona, Montana and Nevada having 208.51, 195.55 and 182.65 miles, respectively, as compared with 5.82 miles per 10,000 inhabitants in Rhode Island and 8.61 miles in Massachusetts.

In the year covered by the report there is still evident a slightly stronger tendency towards the development of existing property rather than to attempt to gain new traffic by extending lines. The percentage of increase in single track for the year 1895 was 1.09, that of second track was 1.34, of third track 2.32 and of fourth track 3.11%; the increase in yard track and sidings was 2.87%. The tendency towards consolidation of interests and greater simplicity in organization and operation is more marked than in previous years. Between 1890 and 1895, inclusive, there has been a decided decrease in lines operated under lease and contract, and a gain in lines owned, from 99,931 miles in 1890 to 125,334 miles in 1895. As showing the general tendency, it may be stated that while the increase in lines owned, between 1890 and 1895, was 25,404 miles, the aggregate extension of railway mileage in that time was only 17.060 miles. The Commission believes that this movement towards greater consolidation will tend to reduce the intricacies of intercorporate contracts which now so much embarrass those seeking to fairly understand the railway system of the United States. From a summary given it appears that 42 railway corporations now operate 100,714 miles of line, or 55.67% of the total mileage; but it may be said here, that for roads operating lines from 250 to 400 miles long and below 250 miles, the percentage of aggregate mileage was about the same in 1895 as in 1890. Of the corporations operating lines over 1,000 miles long, 40 controlled 47.51% of the aggregate mileage, in 1890; showing a general increase of over 5% in lines of that class in six years.

The equipment summaries of the report are especially interesting. With a total of 35,699 locomotives, on June 30, 1895, the increase over the previous year was 207, as compared with an average annual increase of 1,112 for the period 1890-1895 inclusive. The number of cars in service, at the date of the report, was 1,270,561, a decrease of 7,517 as compared with 1894. The freight cars showed a decrease of 9,050, and the passenger cars an increase of 94, and the cars assigned to company service an increase of 1,439. The decrease in the number of freight cars is partly ascribed to the increased use which railways make of private cars; and it is possible that the opportunity presented by slack business for the destruction of a larger number than usual of old and inferior cars may also account for some of the reduction. The average amount of equipment per 100 miles of line changed little or nothing from the year before; the proportion, in 1895, being 20 locomotives and 715 cars, of all types. The assignment of equipment to the amount of traffic, as compared with 1894, shows a decreased efficiency in passenger service and an increased efficiency in freight service. The first is probably due to decreased travel as a result of business depression, and it also suggests that travel has returned to normal conditions after being disturbed for some time by the Columbian Exposition. The freight service shows on its face increased economy in transportation; but the figures are not satisfactory as a large portion of freight moved in cars not owned by railway corporations is necessarily omitted from the computations. The assignment of equipment to the amount of travel, for the two years, is thus summarized:

	1894.	1895.
Passengers carried per pass. locomotive	54,654	50,747
Passenger miles per pass. locomotive..	1,444,400	1,218,967
Tons carried per freight locomotive....	31,909	34,817
Ton-miles per freight locomotive......	4,016,755	4,258,821
Passenger cars per million passengers.	53	65
Freight cars per million tons freight.	1,888	1,717

The report gives the rate of equipment with automatic couplers and train brakes, since 1889, as follows:

Year.	Total equipment.	Increase	Equipment.[1]	Increase	Equipment.[2]	Increase
1895...	1,306,260	*7,310	362,498	31,506	408,856	51,235
1894...	1,313,570	4,836	330,992	31,965	357,621	35,383
1893...	1,308,734	60,506	299,027	42,158	322,238	77,904
1892...	1,248,228	27,139	256,869	68,537	244,334	75,299
1891...	1,221,089	21,282	188,332	39,505	169,035	53,716
1890...	1,199,807	101,205	148,827	20,668	115,319	34,809
1889...	1,098,602	....	128,159	....	80,510	....

*Decrease. [1]Fitted with train brakes. [2]Fitted with automatic couplers.

From this statement it is very evident that the law will not be complied with, which requires freight cars to be fitted with train brakes and automatic couplers by January, 1898. The distribution of this equipment so far as cars of various types are concerned, may be given as follows from the various summaries in the report:

Type of car.	Number equipped with Train brake. 1894.	Train brake. 1895.	Automatic coupler. 1894.	Automatic coupler. 1895.	Total cars in service.* 1894.	Total cars in service.* 1895.	Total in 1895 still to be equipped, with Train brakes.	Auto. c'pl'rs.
Passenger	32,403	32,384	31,916	31,971	33,018	33,112	728	1,141
Freight service	264,884	295,073	317,896	366,985	1,205,169	1,196,119	901,046	829,134
Company service	4,466	4,976	2,676	3,438	39,891	41,330	36,354	37,892
Total	301,753	332,433	352,488	402,394	1,278,078	1,270,561	938,128	868,167
Leased	40,587	38,888	63,996	59,029	181,664	178,107	139,219	119,078
Fast freight	11,510	18,982	16,811	23,122	44,212	49,472	30,490	26,350

*Equipped and unequipped.

So far as locomotives are concerned, practically all passenger locomotives are equipped with train brakes; but 6,106 are still without automatic couplers, out of a total of 9,999 of this class in 1895. Out of 20,012 freight locomotives 16,712 were fitted with train brakes and only 2,039 with automatic couplers, on June 30, 1895. The report gives in detail the types of train brake and automatic coupler in use throughout the United States.

On June 30, 1895, there were 785,034 men of all classes in the employ of railway corporations, as compared with 779,608 in 1894, and 873,602 in 1893. Since 1893 the total number of men employed for each 100 miles of line has decreased from 515 to 441; but the number of men assigned to maintenance of way and structures, per 100 miles of line, was 151 in 1893, 123 in 1894 and 128 in 1895, showing a slight increase in this class of labor in the last year. The number of men assigned to maintenance of equipment, for the same unit of line was 103 in 1893, 86 in 1894 and 88 in 1895; for men engaged in conducting transportation, the ratio was 234 in 1893, 208 in 1894 and 204 in 1895.

From statements of the capitalization and valuation of railway property in the United States on June 30, 1895, the following comparative summary is prepared:

	1890.	1895.
Total stock	$4,409,658,485	$4,961,258,656
Stock per mile of line.....	28,194	28,602
Total funded debt	4,574,576,131	5,385,495,573
Bonds per mile of line....	29,249	31,048
Other indebtedness	453,108,804	616,830,156
Per mile of line	2,958	3,556
Total railway capital....	$9,437,343,420	$10,963,584,385
Total, per mile of line..	60,340	63,206

From another table given it is shown that on June 30, 1895, railway corporations owned 23.57% of all the outstanding stock and almost 10% of the outstanding bonds; the amounts of both held by these corporations being considerably larger than in the previous year; a fact that may be ascribed to railway consolidation rather than to any strengthening of reserve funds. The summary of stocks and bonds paying dividends and interest shows that during 1895 70.06% of all the outstanding stock paid no dividends and 16.71% of the funded debt paid no interest. This is the largest failure in payment, for both classes of securities, for any one year since the Commission was organized. The percentage of dividend paying stocks has decreased from 38.56% in 1888 to 29.95% in 1895.

The comparative passenger and freight service for the years ending June 30, 1890, 1894 and 1895 are summarized as follows:

	1890.	1894.	1895.
Pass. carried ..	492,430,865	540,688,190	507,421,362
Per mile of line	75,751	81,333	68,572
Tons:			
Freight car'd.	636,541,617	638,186,553	696,761,171
Car'd 1 mile..	76,207,047,298	80,335,104,702	85,227,515,891
Average haul* .	119.72	125.88	122.32

*Per ton-mile.

These figures indicate a marked decrease in the number of passengers carried in 1895 as compared with the previous year; but the freight traffic shows an increase over 1894. The gross income from the operation of the railways of the United States for the year ending June 30, 1895, was $1,075,371,462, an increase of $2,009,665 over 1894. For the same period the expenses of operation were $725,720,415, a decrease of $5,693,907 over 1894. The net income from operations was $349,651,047, an increase of $7,703,572 over 1894, but excepting that year it is the least of any year since 1890. The earnings from passengers, in 1895, amounted to 29.16% and that from freight to 68.27% of the total earnings from operation. The percentage of operating expenses to operating income is gradually increasing; this item being 65.80% in 1890; 66.73 in 1891; 66.67 in 1892; 67.82 in 1893; 68.14 in 1894 and 67.48% in 1895.

The Commission gives a general summary of results, as deduced from their numerous tables, covering the period 1890-1895 inclusive, and the whole United States. This table is interesting as showing the late trend in revenue and cost of operation and it is given in full as follows, the cents being reduced to the nearest decimal:

Item.	1895.	1894.	1893.	1892.	1891.	1890.
Revenue per passenger per mile	$0.02040	$0.01986	$0.02108	$0.02126	$0.02142	$0.02167
" per ton of freight per mile	.0839	.0860	.0878	.0898	.0805	.0941
" per passenger train-mile	.98	1.05	1.07	1.07	1.06	1.08
" per freight train-mile	1.61	1.56	1.63	1.65	1.64	1.65
" per train-mile, all trains	1.36	1.37	1.43	1.45	1.43	1.44
Average cost of running a train 1 mile, all trains......	.09182	.09348	.09727	.09658	.09571	.09601
Per cent of operating expenses to operating income....	67.48	68.14	67.82	66.67	66.73	65.80

Had the rates of 1890 been maintained in 1895 the passenger revenue would have been increased for the latter year by $15,479,326, and the freight revenue by $86,932,066. From this it appears that if we take the rates of 1890 as a standard, the people of the United States have saved, in passenger and freight charges in a single year, a sum exceeding $100,000,000. With the above statement and as illustrating the effect of the business depression upon railways, the report states that as contrasted with a surplus from operations of $8,116,745 in 1893 and $14,036,056 in 1892, 1894 showed a deficit from operations of $45,851,294, and 1895 shows a deficit of $29,845,241.

The length of line operated by the 75 companies whose gross annual revenue exceeds $3,000,000, is 119,810 miles, or 67.41% of the total operated mileage. The aggregate revenue of these 75 companies is $874,542,695, or 81.32% of the total gross revenue for the entire country, which was $1,075,371,462. For these companies the average gross revenue per mile was $7,299 as compared with $6,050, the average per mile of line of all roads; they perform 84.08% of all the passenger service and 84.55% of the total freight service. The chief interest centers in the fact that while this group of roads enjoyed a net revenue of $2,862 per mile of line in 1890 this was reduced to $2,425 in 1895; a decrease of $437 per mile of line, equivalent to a total reduction of about $50,000,000 in net revenue, for 1895, for the roads under consideration.

The total number of railway employes killed in 1895 was 1,811 and 25,696 were injured. This is a decrease, over 1894, of 12 killed and an increase of 2,274 injured. Of passengers, 170 were killed and 2,375 injured; a decrease of 154 over the killed and 659 in those injured in 1894. The record for 1895, in respect to the number of passenger casualties is less than for any year for which complete statistics are available. The statement of "other persons" for 1895, foots up 4,155 killed and 5,077 injured, as returned to the Commission. The total chargeable to railway accidents, for 1895, is 6,136 killed and 33,748 injured. A summary of employes and passengers killed and injured in the United States in 1890-1895 shows that the record for 1895 is more satisfactory than for any previous year of record; the number of employes killed has decreased from 1 in 306 to 1 in 433, while those injured have decreased to 1 in 33 from 1 in 31 in 1890. The number of passengers killed was 1 in 1,727,780 in 1890, and 1 in 2,984,832 in 1895; while the proportion of passengers injured has decreased from 1 in 203,064 in 1890, to 1 in 213,651 in 1895. The Commission believes that the fitting of equipment with automatic devices is beginning to show a beneficial effect; as while 1 trainman in every 105 was killed in 1890, the ratio in 1895 was 1 to 155.

The Commission renews its recommendations of previous years, and further recommends that Congress establish a Bureau of Statistics and Accounts, which shall have the right of inspection and control of the accounting departments of the common carriers. This bureau was suggested in the ninth annual report of the Commission and the considerations favoring it are given in full.

A NEW WATER-METER.

A simple form of positive water meter adopted for general service has recently been perfected by the National Meter Co., of New York city, by making some important changes in its "Empire" meter. This meter has been in use for a number of years, but principally for measuring hot water and other liquids requiring all-metal construction.

The general design of the new meter is shown by the accompanying illustrations, Figs. 1 to 3. Fig. 1 shows the cylinder and piston, the top cylinder head being thrown back to show the piston in place, Fig. 2 shows the base and screen, and Fig. 3 the whole meter, in two parts, the cover being thrown back to show the intermediate gearing.

The piston is of hard rubber, having the same specific gravity as water. It has a revolving motion around the centre of the case and an oscillating motion on its axis.

The base casting is made considerably thinner than the cap, and the bulk of the water in the meter being in the base, in case freezing occurs, the base will be the only part injured, and the moving parts, register, etc., will not be affected. This greatly simplifies and cheapens the work of repairing frozen meters.

The meter has a straight reading register, which is instantly read without liability to error. and is provided with the same style of intermediate gearing that is used in the Crown and Nash meters, made by the same company.

Another point claimed for the meter is that if the piston stops for any reason it shuts off 85% of the normal flow through it. By this means the consumer, while not absolutely deprived of water, is pretty sure to notify the water department, or otherwise see that the meter is set right, instead of placidly continuing to use the water without having it charged against him.

The old meter, designed, as stated, for special service, had a gun metal piston. The new meter has a rubber piston, giving great lightness, and its proportions have been changed to give greater strength. The latter has been effected by increasing the diameter and decreasing the height, or length, of the piston, which strengthens the latter at the lips, or where the ring of the piston is cut away for the bridge, as shown in the left of Fig. 1. For special service, as for measuring hot water, the new shape will be used, made of metal as before.

The main wear of the meter comes on the cylinder heads and the top and bottom of the piston. The former can be easily tooled down to a plain surface, and the latter can be offset by shortening the cylinder ring, both processes requiring only simple tools and ordinary skill. Of course these processes could not go on indefinitely without using up too much of the material and seriously impairing the accuracy of the meter, but they might be so employed as to greatly increase the life of the meter, especially as under ordinary circumstances the wear would be very small. What is most feared now, it may be added, in the wearing out of meters, is sharp, gritty matter, of some size, rather than finely divided, smooth particles of mud and clay, such as is carried by the Ohio or Mississippi and most rivers of the West and South.

◆

A NEW PROCESS FOR THE DIRECT PRODUCTION of iron and steel from the ore is being introduced in Sweden by Dr. De Laval, the well-known inventor of the cream separator and the De Laval steam turbine. According to a description in the "Iron Age" by Mr. Fred. H. Daniels, general superintendent of the Washburn & Moen Mfg. Co., of Worcester, Mass., who has recently returned from Sweden, the process consists in mixing pulverized iron ore with carbon, probably in the form of pulverized peat, and subjecting the same in some form of a rotating cylinder to heat, after which it is brought into direct contact with an electric arc of tremendous power, which reduces the ore to metallic iron. The melted iron then flows into a large and highly heated furnace, where it can either be manufactured directly into steel or cast in any suitable form for further treatment. Dr. De Laval commenced his experiments something like three years ago at Trollhattan. During this period he has been assisted by a competent corps of mechanical engineers and metallurgists, and it is evident these experiments have produced results, from the fact that he has purchased one side of the entire water power at Trollhattan, which is made up of four falls, an aggregate horse-power of from 60,000 to 70,000. He has also purchased at considerable expense very much larger water powers in the north of Sweden. It is interesting in this connection to note that quite a number of the iron and steel works in Sweden have become so interested in the possibilities of this process that they have purchased all of the available water power in their vicinity.

◆

A NEW AND LARGE DEPOSIT OF IRON ORE of the finest Bessemer quality has been discovered at Iron Mountain, Mich., according to a press despatch. It was discovered when the water was turned into the new channel dredge for the Michigamme River, for the purpose of reclaiming the Mansfield mine, which was flooded several years ago, drowning 27 men. Six inches below the sand covering the river bed was found the new bed of ore, which was traced nearly 300 ft. The depth has not yet been tested.

◆

AN OHIO RIVER SURVEY is being made for the U. S. Government by Mr. R. R. Jones, U. S. Assistant Engineer under Major W. H. Heuer, Corps of Engineers, U. S. A. It is officially known as the Marietta-Pittsburg Survey, and covers about 180 miles of the river, and comes under the Act of Congress appropriating $1,100,000 for the construction of locks and dams, Nos. 2, 3, 4 and 5. This survey is to be the most exhaustive ever made of this part of the Ohio River, covering the position of the channel, location of channel eddies, shallows, bars, islands, geological formation of the banks, high and low water marks, velocities and volume of the river and precise leveling. The last authentic survey from Clipper Mills to Cairo, a distance of 696 miles, was made in 1868; the river, from Clipper Mills to Letarte, 37 miles, was last surveyed by C. A. Fuller, in 1844, and the 234 miles, from Letarte to Pittsburg, was last surveyed in 1837, says the Pittsburg "Chronicle." It is evidently time that the whole river was resurveyed, and those most interested expect that Congress will order the continuation of the present survey so as to cover the whole river, from Pittsburg to Cairo, at least.

◆

BRIDGES OVER THE OHIO RIVER, between Pittsburg and Cairo, number 22. The list is given as follows by the Pittsburg "Chronicle" in connection with a protest from rivermen against the manner in which they are built, the height above low-water mark is included: Point bridge, highway, 73.3 ft.; Ohio Connecting railroad, 83.5 ft.; Rochester, under construction; East Liverpool, building; Beaver, highway, 88.9 ft.; Steubenville, highway, 89.6 ft.; Wheeling and Marietta, highway, 91.66 ft.; Wheeling suspension, highway, 91.5 ft.; Wheeling bridge, 96.2 ft.; Bellaire, railroad, 90 ft.; Marietta, building; Parkersburg, 90 ft.; Point Pleasant, railroad, 91.4 ft.; Ceredo, railroad, 98 ft.; Newport and Cincinnati, railroad and highway, 98.1 ft.; Newport and Cincinnati, highway, 102 ft.; Covington and Cincinnati, highway, 105.5 ft.; Chesapeake and Ohio, railroad, 104.4 ft.; Cincinnati Southern, railroad, 105 ft.; Louisville and Jeffersonville, railroad, 92.8 ft.; Ohio Falls, 92.8 ft.; Kentucky and Indiana, railroad, 106.5 ft.; Henderson, 101.3 ft.; Cairo, 105.2 ft. In addition to these charters have been granted for bridges at McKees Rocks, Sewickley, Ironton and several other places. Ten years ago the rivermen succeeded in having a law passed requiring all bridges over the Ohio and below the Kanawha to give a clearance of at least 90 ft. above low-water mark. They now demand a channel span of 800 ft. instead of the 500 to 550 ft. used in the later structures.

◆

THE POTOMAC RIVER RETAINING WALL, at Washington, D. C., is almost completed. This wall, which will be nearly six miles long when finished, was authorized in 1882 as a protection to the land filled in and reclaimed on the Washington and Georgetown side of the Potomac River in the improvement of that river. The reclaimed land is in three sections, aggregates 621.12 acres, and this area is set aside for park purposes. The wall, commenced in 1890, is now 28,172 ft. long, and 2,000 ft. are yet to be built. It is founded upon a riprap base 20 ft. wide at the bottom and 5 ft. at the top and the wall itself is 6 ft. high and about 3½ ft. thick, extending 3 ft. above high tide. The wall is backed with oyster shells or gravel and back of this is the filling material taken from the Washington Channel, deepened under the same act of Congress. A tidal basin is included in one of the filled areas, and this basin is provided with automatic gates admitting water at high tide from the Georgetown channel and emptying it into the Washington channel at low tide.

BLACK AND WHITE ASPHALT ROADWAYS have been proposed by the Public Works Department of New York for the Western Boulevard. The purpose is to separate the truck, or heavy vehicle traffic, from the light traffic, by dividing the 26-ft. roadways on each side of the car tracks into two distinct roadways by the difference in color. This would only be done in case of the passage of an ordinance now before the aldermen compelling trucks to keep to the gutter side of the street and leaving the inner half of each roadway clear for light traffic. An alternate plan proposes a 1-ft. strip of white asphalt as an indicator of the dividing line of traffic. Since writing the above, the ordinance has been passed.

◆

A TREADLE-MOTOR HOSE CARRIAGE is being tried by the Berlin Fire Department. This carriage carries six men; two in front, who attend to the steering, while four men in the rear operate a treadle which communicates motion to the two rear driving-wheels by belts. The body of the vehicle is made of wood and steel tubes and the apparatus is claimed to be generally successful in operation. This standard of excellence, however, is based upon the comparatively slow methods of the German fire department.

J.—Hydrographic Surveys on the Outer Bar of Brunswick, Ga.

THE DESIGN FOR A BASCULE BRIDGE, prepared by Mr. Thomas E. Brown, Jr., M. Am. Soc. C. E., of New York city, has been adopted for the crossing of Newtown Creek at Vernon Ave., Brooklyn, N. Y., by the joint bridge committee of the Brooklyn board of aldermen and the Queens County board of supervisors. The clear span is to be 150 ft., and the bridge will have two leaves 85 ft. long, with 75-ft. swing, operated by cables passing over sheaves in towers on the abutments, these cables being attached to three points in each leaf. The hoisting plant will be operated by hydraulic power. It was at first proposed to have a swinging leg under the free end of each leaf, to rest on a foundation in the bed of the creek when the bridge was closed, but this feature has been wisely abandoned. The bridge will have a 34-ft. roadway, two 6-ft. sidewalks, and will be 8 ft. above the water line. The estimated cost is $105,000, or $200,000 including the piers. Mr. John J. McLaughlin, M. Am. Soc. C. E., County Engineer of Queens County, is engineer for the bridge committee. Some of the other competitors have entered protests against the acceptance of the Brown designs, but the committee has decided to ignore them.

◆

THE COLUMBIA BRIDGE, over the Susquehanna River, at Columbia, Pa., was swept away by the recent great wind storm. This bridge was about 1¼ miles long, and was claimed to be the longest covered bridge in the country. The first bridge at this point was completed in 1812, at a cost of $232,000, but the structure was carried away by an ice freshet in 1832. It was rebuilt at an expense of $157,300, and was burned in June, 1863, to prevent the passage of Confederate troops, who were then in the adjoining county to the south. The Pennsylvania R. R. Co. bought the old piers and, in 1869, built a wooden railway bridge across the river, with one iron span in mid-stream. This bridge was used for freight trains to Baltimore and other points. The iron span alone remains. The storm lifted the wooden spans clear from the piers, but left the latter uninjured.

◆

THE NEW YORK & BROOKLYN RY. CO. has filed a certificate of incorporation for the purpose of building and operating a railway tunnel between the two cities, two miles long. The New York end would be near Broadway, somewhere between Canal St. and the Battery, and the Brooklyn end would be near Fulton St., "between the City Hall and the East River." The capital named is only $20,000, and the directors for the first year are Alonzo B. Cornell, B. S. Henning, Otto Andrae, Jr., Fritz Hill, J. D. Miller, Jr., P. C. Schnitzer, S. R. Haxtun, E. R. Hoadley and Irving Washburn. This is apparently a revival of the Henning gravity railway tunnel project.

◆

THE IMPROVEMENT OF THE EAST RIVER FRONT of New York has been reported upon by the board of consulting engineers, made up of Mr. George S. Morison, Prof. William H. Burr, and Gen. William P. Craighill. This report supplements that of Feb. 6, 1896, on the North River front, given in abstract in this journal. In the former report provision was made for railways along the proposed marginal North River street and the board believes that the same should be done for the East River, and some radical changes are called for in this connection. A large part of the freight traffic of the New York, New Haven & Hartford R. R. naturally comes to this section of the city and it would seem better to reach this district by land than by water. A single large ferry-house at the Battery would also better suit public convenience and occupy less space than the several existing houses. The board considers the transfer of the Sound steamboat business from the North to the East River as desirable, and as better accommodating the public by saving at least a half hour in time; but the transfer involves so many questions that it must be handled with a great deal of care. The full report divides the East River front into four sections and discusses each section with reference to docks, piers, etc.

◆

THE DREDGING OF THE CHICAGO RIVER, ordered by the U. S. Government and to be commenced on Nov. 15, is likely to destroy abutting dock property if early precautions are not taken by the owners. The contract calls for the removal of 1,306,942 cu. yds of material and an increase of the depth of the river to 17 ft. Many docks and other structures on the banks are founded at a depth of 12 to 15 ft., and Capt. Marshall, Corps of Engineers, U. S. A., now warns property-owners that they cannot recover damages from the U. S. Government if their docks are undermined and slide into the river. On the contrary, if such accidents occur, the owners make themselves liable to penalties, under the law relating to the obstruction of navigable channels being improved by the government. After the government has finished its work, the Drainage Channels Trustees will increase the depth in places to 24 ft., thus adding to the danger to adjacent property.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week was a derailment caused by the explosion of the boiler of a locomotive Oct. 4, near Osage City, Kan., on the Atchison, Topeka & Santa Fe Ry. The engine was hauling a passenger train and should have stopped at Osage City for water, but being late it was run on towards the next water station. When about two miles beyond the city the boiler exploded, and as a result of the sudden check some of the forward cars were telescoped, and others were overturned, while all the cars were derailed. There were seven persons killed (including the engineman and fireman) and four or five injured.——A train of freight cars on the Quinnimont Coal & Iron Ry., near Quinnimont, W. Va., ran away on the steep grade Oct. 7 and left the track at a sharp curve. The engine and all the cars were wrecked; two men were killed and two others badly hurt.

◆

A LOCOMOTIVE BOILER EXPLOSION occurred Oct. 7 at Meriden, Conn., on the New York, New Haven & Hartford R. R. The engine was hauling a northbound freight train at the time. Nobody was killed or badly hurt.

◆

A BOILER EXPLOSION at the Montour Iron Works, Danville, Pa., on Oct. 8, killed six persons and seriously injured 30 more, some of them being fatally injured. The boiler was about to be put out of service to allow of repairs being made, and men were at work repairing the brick work of the furnace.

◆

AN EXPLOSION IN A FOUNDRY CUPOLA occurred Oct. 8 in the works of the Singer Sewing Machine Co., at Elizabeth, N. J. The iron had just been tapped and run off and the furnace men were moving away when the side of the cupola was blown out. Two men were badly injured and burned.

◆

AN EXPLOSION OF ACETYLENE GAS occurred Sept. 12 in a restaurant at Lyons, France, causing a great amount of damage to the building and the neighboring buildings, while five persons were injured. The fire underwriters submitted a report on the case to an expert, who gave the opinion that the acetylene system may be accepted if an additional premium is charged, and the apparatus installed outside the building or in an unoccupied and well ventilated place.

◆

THE AMERICAN LINE STEAMSHIP "PARIS" was disabled, on Oct. 2, by the fracture of the starboard shaft in the tube next to the outboard shaft tube. The "Paris" was 320 miles east of Sandy Hook at the time of the accident bound to Southampton. She proceeded on her journey with one engine, at the reduced speed of about 15 knots per hour, after sending the news to New York by the "Fuerst Bismarck."

◆

STREET CAR FENDERS OR WHEEL GUARDS which can be dropped by a catch operated by the motorman are to be tried at New Haven, Conn., the Railroad Commissioners having given permission for the use of these fenders instead of the present ones which are operated by an automatic trip released by any obstruction on the track.

◆

THE BROOKLYN NAVY-YARD CAISSON ACCIDENT is practically disposed of by the announcement that the Secretary of the Navy will take no further action in the case. Experts called during the final sitting of the court of inquiry declared that the calculations of Mr. Menocal were entirely correct and that by these figures he was justified in removing the ballast. His friends also contend that other and unknown causes may have been at work, as no one knows what happened in the several hours intervening between the completed removal of the ballast and the accident. As the Secretary has expressed doubts as to Mr. Menocal's responsibility, it is understood that he is to have the benefit of this doubt.

◆

AIR-POWER FROM COMPRESSED AIR is being supplied to all tenants of the Havemeyer Building, New York, who may desire it, by the Ingersoll-Sergeant Drill Co., which has its offices in the same building. A steam-driven compressor is located in the engine-room and the building is piped throughout, through the elevator shaft, with branches at the several floors. The Ingersoll Company will be the largest consumers in operating tools and machines of all kinds for exhibition; but this power is also used in their offices to open the doors, ring call bells, operate the letter presses, dust furniture and clean the carpets, rugs, etc.

◆

AN ELECTRIC PLANT, to be operated by water power, is in course of construction at Tampa, Fla., by the Consumers' St. Ry. & Power Co. A wing dam has been constructed across the Hillsborough River, which is stated in a press report to be 22 ft. high with a 60-ft. base. The river flow is 50,000 cu. ft. per minute. The total horse-power of the plant is 1,400. A steam plant is also to be added for use when the steam is low.

◆

THE BOSTON PNEUMATIC TRANSIT COMPANY'S permission from the Boston Aldermen to lay and operate underground pipes in that city has been vetoed by Mayor Quincy. The ground of objection is that the franchise is not accompanied by a contract protecting the interests of the city and securing some pecuniary returns to the city treasury. The grant from the Aldermen simply defined the route and stipulated that the company shall transport free all matter pertaining to the official business of the City of Boston which can be transmitted through its system.

◆

LOW BIDS FOR CEDAR BLOCK PAVING were recently received at Port Huron, Mich., the contracts being awarded at 37 cts. per sq. yd. for cedar blocks upon a sand foundation. The detailed bids were published in our Construction News Supplement last week. Mr. F. F. Rogers is City Engineer.

◆

THE PRESENT AND FUTURE WATER SUPPLY OF Brooklyn is discussed at some length in a special report by Mr. I. M. de Varona, M. Am. Soc. C. E., Engineer of Water Supply, made public Oct. 6. Mr. de Varona was requested to report on the cause of and remedies for the recent taste, odor and color in the Brooklyn water supply, the time when an additional supply, outside of sources now under development, would be needed, and the best means of securing such a supply. The report states that the cause and remedies cannot be stated with definiteness until the water has been more extensively studied, especially from a biological point of view. The general cause of the taste and odor is decaying organic matter, but whether this arises chiefly from growths in the surface or driven-well supplies cannot yet be said. An additional water supply, Mr. de Varona says, should be available in five years, which would require the immediate beginning of construction. Further investigations for a new supply must be made before selecting the source. Although strongly in favor of municipal control of all portions of a municipal water supply, Mr. de Varona believes that financial conditions may make desirable a contract with a private company for the development and delivery of more water, with ultimate private ownership.

◆

AN EXHIBIT OF VALVES AND HYDRANTS and their accessories will be held on Nov. 10, by the Department of Public Works of New York city. Manufacturers of such supplies are requested to send illustrations and literature explanatory of the same to Gen. Chas. H. T. Collis, Commissioner of Public Works, 150 Nassau St. Only articles selected will be placed on exhibit. The exhibit will be held at the corporation yard. Exhibitors must bear all the expense of their respective exhibits and have a representative on hand to explain the same. The mayor, board of underwriters, engineers of city departments and the press will be invited to inspect the exhibit and "experienced judges will be appointed to examine and report upon the merits." The object of the exhibit is stated to be "to ascertain the state of the art relative to such contrivances with a view to improving the city service." All communications on this subject should be addressed to Gen. Collis, as above.

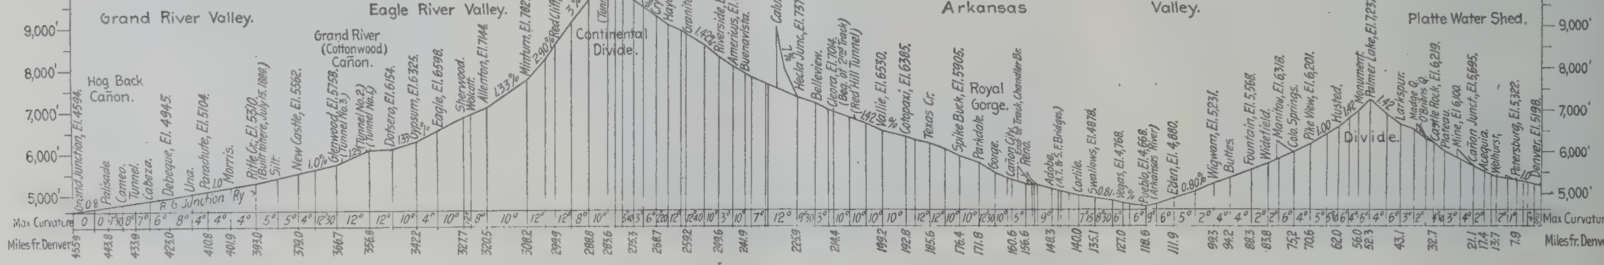
NOTES OF A TRANSCONTINENTAL TRIP.

III.

Denver & Rio Grande R. R.

This noted railway was first projected and built at the time when the narrow gage fever was at its height among promoters and engineers, and a 3-ft. gage was adopted as promising a lower cost in construction and operation and a greater facility for the sharp curves of a mountain railway than could be obtained with the standard gage. The construction was commenced in 1871, and for a long time this railway was held up as an example of the benefits of a narrow gage line, especially for mountain railways, the old arguments about the lower cost, the greater facilities for sharp curves, the greater proportion of live load to dead load, etc., being worked pretty hard for some years. As the fallacies of these arguments became more fully recognized, and as the standard gage system extended, the Denver & Rio Grande R. R. became isolated, possessing no facilities for through traffic. This led to the adoption of the standard gage, and the change was commenced on the main line between Denver and Pueblo, in the summer of 1880, at which time the system had a total extent of 337 miles (all narrow gage), but it was not until 1890 that the standard gage track was completed through to Grand Junction, the western terminus (and the connection with the Rio Grande Western Ry.). The line has now 305 miles of standard gage main line from Denver to Grand Junction (via Pueblo and Leadville), and south from Pueblo to Trinidad; 296 miles of narrow gage main line, extending from Salida south to Santa Fe, N. M., and west to Grand Junction (via Gunnison); and 278 miles of mixed gage, from Denver to Pueblo and Leadville. This latter is maintained in order to provide for through trains over both lines and also for the through haul of ore from the narrow gage branches at the mines about Leadville to the smelters at Pueblo.

Some interesting notes on the rails used on this line, with illustrations of the various sections from the 30-lb. rail of 1871 to the 85-lb. rail of 1896, were given in Engineering News of Sept. 3. Reference was there made to the use of a combination of 85-lb. and 65 lb. rails on the mixed gage on three-rail track, so that one of the outer (85-lb.) rails carries wheels of standard gage rolling stock only, while the other carries the wheels of both standard and narrow gage rolling stock. In answer to an enquiry as to the relative wear of these rails, Mr. M. H. Rogers, Chief Engineer, stated that thus far very little difference has been observed in the wear of these rails. The narrow gage trains passing over this track are usually hauled by standard gage engines, so that no difference in wear on the two rails would be due to the engines, and the load on the wheels of the narrow gage freight cars is small in comparison with the load on the driving wheels of the engine. It is to be remarked, however, that the difference in height of the two rails forming the narrow gage track probably have some influence on the steadiness of running of the trains and on the wear of the wheels and trucks. On another page of this present issue is shown the track construction with 85-lb. rails, and also a turnout and crossover on the mixed gage track, where the three rails make a somewhat complicated arrangement. The stub switch is almost universal. Some of the new 85-lb. rails are being laid south of Colorado Springs, new ties are being put in (and they are badly needed in places), and a considerable amount of gravel is being put in to raise the track to grade and shoulder out the ballast.



PROFILE OF THE DENVER & RIO GRANDE R. R.

There are some very fine locomotives on this line, but no very new narrow gage engines, as the extension of the standard gage system has given the road a surplus of these and none have therefore been built or bought for some time. Both diamond-top and straight smokestacks are used. The narrow gage freight engines were originally built with diamond stacks, and have never been altered, but the straight stack and extension smokebox are the present standard, and are applied on nearly all the standard gage engines, and narrow gage engines in passenger service. It was noted that the height of most of the straight stacks had been increased by putting on a piece extending about 12 ins. above the top molding of the original stack. On enquiry it was found that this has been done on account of the trouble experienced from smoke blowing into the cab when steam was shut off. The straight stacks are made as high as possible consistent with the limits imposed by bridges, tunnels, etc. The doors of some of the roundhouses, however (built for narrow gage engines), are unusually low, and the tops of the smokestacks are made movable so that they can be removed by the hostler when the engines are put into the roundhouse. Mr. Henry Schlacks is Superintendent of Machinery.

The main shops are at Burnham, just outside Denver, but there is not much work going on, with the exception of ordinary repairs and some new narrow gage car work. From the look of a number of driving and truck wheels waiting to have their tires re-turned, it would seem that a limit of tire wear is not very closely observed, but that engines are allowed to wear their tires pretty hollow before being sent to the shop. The responsibility for this may perhaps rest with the traffic department rather than with the mechanical department, as is the case on a good many roads.

Frogs (rigid) and switchstands are manufactured at these shops. The narrow gage sleeping cars and day cars are practically the same as those for the standard gage lines, except that they are somewhat smaller and have narrower berths and seats. The narrow gage sleeping cars were all built by the Pullman Palace Car Co.

Denver to Salt Lake City (D. & R. G. R. R. and R. G. W. Ry.).

All narrow gage trains on the mixed gage portions of the Denver & Rio Grande R. R. are hauled by standard gage engines, the drawheads on the tenders having three sockets (side by side) for the coupling pin, so as to fit the coupling of standard and narrow gage cars. The narrow gage engines are also similarly fitted, so as to haul either narrow gage or standard gage cars. The New Mexico express (for Santa Fe, N. M.) by which I traveled from Denver to Colorado Springs on July 7, is a narrow gage train hauled by a standard gage engine, a shackle bar (like that on an engine pilot) connecting the drawhead on the car with that on the tender. Owing to this arrangement an extra length of brake hose was required between the tender and car, but as this sagged to the ground the brakeman gave it two turns around the shackle bar, so that a casual observer (even uninfluenced by Colorado whiskey) might not unreasonably have thought that he saw a snake crawling from the engine to the train.

The California Fast Mail, on which I left Colorado Springs, July 9, is a standard gage train with through cars to San Francisco. It has no dining car, but stops at Pueblo for lunch and at Leadville for dinner. At the former place there is a handsome station, with a very poor lunch room, the principal article of food available being the usual imitation chicken (apparently manufactured of leather and parchment specially for railway use). At Leadville the station does not amount to much, but there is a good and plentiful meal provided. The hurry and scramble, however, are very objectionable and trying, and while the patronage does not probably warrant running a dining car service it would seem as though a buffet car service might be afforded.

Pueblo, 120 miles from Denver, is an important railway center and a manufacturing city, having the large iron and steel works and rolling mills of the Colorado Fuel & Iron Co., flour mills, and extensive smelting and reduction works for the treatment of the ores brought from the mining districts. It is 4,667 ft. above sea level and has a population of 35,000. At Florence, the junction of the branch to Cripple Creek, are sidetracks crowded with cars loaded with machinery and supplies for, and ore from, the Cripple Creek gold mines. Oil and coal are found in this vicinity, the present output being given as 5,000 tons of coal and 2,000 barrels of oil per day, while natural gas is supplied for domestic use. The railway now approaches the mountains, following the course of the Arkansas River, and then enters the Grand Canyon of the Arkansas at the narrowest part of which (the Royal Gorge) the walls rise almost vertically for a height of, in some places, 2,600 ft. For eight miles the line runs along the bottom of this narrow and tortuous gorge, following every curve and bend of the river, and not far above the water, the roadbed being in many places a gallery cut in the face of the rock. In this gorge is the notable plate girder bridge over a tributary stream, the outer girder being suspended at the middle from an iron inverted V spanning the Arkansas and abutting in the rocky walls of the canyon. This bridge was described in the "Transactions of the American Society of Civil Engineers." The noise of the rushing water and the reverberating roar of the train are almost deafening. Salida (elevation 7,049 ft.) is the junction of the two main lines to Grand Junction (one standard gage and the other narrow gage), and the narrow gage line to New Mexico. At Granite (elevation 8,945 ft., 259 miles from Denver) are extensive placer mining workings.

Just beyond Granite, while running along an embankment, the engine (a ten-wheeler) struck a boulder lying on the track, throwing it to one side so as to derail the front pair of truck wheels. Fortunately the truck did not slew very much out of line, and the train made an emergency stop in three or four car lengths, with the wheels not far from the rails. Wrecking wedges or frogs of hard wood were put behind the wheels, and the engine backed up until the wheels dropped into place on the rails. The delay did not exceed 10 or 15 minutes.

Leadville is reached by a long loop with heavy grades, and two engines are used for the ascent, taking a run at the grade at high speed and going up in fine style. This city was the center of a great gold mining district from 1859 to about 1870, being then known as California Gulch. It then became partially abandoned, but the discovery of the carbonate silver ores in 1876 gave it a new start, under its present name, and it is now the center of a silver mining industry, its population being about 20,000. Its elevation is 10,200 ft. above sea level, but the highest point reached by the railway is the summit of the Tennessee Pass, 10,240 ft., where a tunnel effects the passage from the Atlantic to the Pacific slopes. The Grand River canyon and the 250 miles of the Colorado Desert were passed at night. At Grand Junction, 456 miles from Denver (elevation 4,594 ft.) the two lines of the D. & R. G. R. R. from Salida and the line of the Colorado Midland R. R. converge. This point is the western terminus of the Denver & Rio Grande R. R. proper, but the Rio Grande Western Ry., which extends from here to Salt Lake City and Ogden is practically an extension thereof, giving the D. & R. G. R. R. a connection with the Southern Pacific Ry. for through communication with the Pacific coast.

THE TABERNACLE, SALT LAKE CITY.

THE TEMPLE, SALT LAKE CITY.

Soon after passing Grand Junction, the line crosses the 250 miles of the Colorado Desert, a rolling plain of fine sand which I first saw about 5.30 a. m. on July 10, when near Green River. The sand permeates everywhere in spite of double window sashes and closed ventilators and doors. From this plain rise rows and blocks and pillars of rock, with vertical sides and horizontal strata, their outlines (as cut by the sand and wind) resembling massive castles and long lines of fortifications. The main range of these hills, north of the railway, is said to be 2,000 ft. high, and there are seams of coal visible, while in the higher plateau, north of the cliffs which form the face of the hills, are deposits of asphalt, gilsonite, ozocerite, etc. The sand of the desert has enough loam in it to break into a thin crust or scale, cracked like the bottom of a dry pond, while the irregular surface is gullied and washed, showing the effects of the heavy rainstorms which sometimes occur. It is said, on good engineering and agricultural authority, that the land is richly fertile if watered (being specially adapted for fruit growing), and that sufficient water can be obtained from the Grand River, and other rivers in the neighborhood, to enable a large part of the desert to be reclaimed. In fact a considerable amount of reclamation has already been effected. An example of what may be done here by irrigation is afforded at the little town of Helper, where the train stopped for breakfast (July 10), and where the bright fresh green of the trees, bushes and lawns, and the spray from numerous lawn sprinklers, were most refreshing after the unbroken yellow and gray colors of the desert. Similar oases are to be seen at Price and other stations. In addition to this, there are great coal deposits underlying this district, and west of Helper there are coal mines and nearly 100 coke ovens.

Leaving the desert the railway begins to descend the Wasatch range to the Utah or Jordan valley by a long steep grade full of curves. The summit of the grade is 7,465 ft. above sea level. The brakes are kept on most of the time, and the brakemen are on the alert, standing in the vestibules ready to pull the emergency cord in case of necessity. The speed is about 35 to 40 miles an hour, checked at sharp curves, and, of course, a hot box developed. It was on a mail car, and the journal had a lead-lined bearing. A copious application of cold water enabled the repair men to change the brasses and repack the box in a very short time, the journal, of course, being popularly supposed to be able to take care of itself if heated to a high temperature, and then dosed with cold water. At Midway, on this steep grade, is a catch siding with switch set normally for the siding, so that a runaway train will be diverted from the main track and turned onto the sand. Above the switch tower is a "Stop" sign, and the train comes to a full stop here, the towerman not setting the switch for the main track until the train is at rest.

In the valley there is more vegetation, with signs of the irrigating ditches, by means of which the sagebrush desert has been converted into orchards, farms, and gardens. The bottom of the valley, between the toes of the mountain slopes, is almost perfectly flat. Besides agriculture, there is the mining of rock salt, soda, gypsum and kaolin. Most of the towns here are practically Mormon towns. After seeing so much sandy desert and barrenness, the sight of the blue waters of Utah Lake is wonderfully refreshing to the eye and mind. This is a fresh water lake, about 10 × 30 miles, and from this the little Jordan River flows to the Great Salt Lake. At Provo is a woolen mill employing some 500 men, and at American Fork is what is said to be the largest beet-sugar factory in the country. The line passes the junctions of several branches to coal and gold mining districts (including that of the Salt Lake & Mercur Ry., described and illustrated in Engineering News, July 2, 1896), to the soda beds at Manti, to the rock salt deposits at Salina, and to the deposits of gypsum and potters' clay. The Mercur gold mining district is spoken of as a rival of the Cripple Creek district in point of importance, but I learned that considerable difficulty has been and is being experienced in satisfactorily extracting the precious metal from the ore. The cyanide process is used, with some modifications. After all these places the railway enters Salt Lake City, which I reached about 1 p. m. on July 10.

Salt Lake City.

It must be acknowledged that this city is somewhat disappointing in its first appearance, and hardly comes up to one's expectations. The streets are wide, but not in very good repair on the whole, and are very dusty. The irrigation ditches along the streets are either lined with cobblestones or overgrown with rank grass, and even the grass along these ditches is yellow, burnt and dusty in July. Nevertheless, the city is certainly imposing, and from a little distance one realizes that it actually is an oasis in the flat valley, few trees being seen outside of the irrigated limits.

The city is 4,228 ft. above sea level, and has a population of 50,000. It was laid out by the Mormons in 10-acre squares (666⅔ ft. square), with streets 132 ft. wide, every street having a stream of water flowing along each side (either in a ditch or in an ordinary gutter), and most of the streets having plenty of large trees. There are many modern office buildings, and the municipal and county offices are in a handsome structure known as the City and County Building, shown in the accompanying illustration. It is of Utah stone, from Kyune, and is 160 × 273 ft., 250 ft. high to the top of the dome. The two wonderful buildings here are the Tabernacle and the Temple, both situated in Temple Square, together with the Assembly Hall. The square covers ten acres, and is surrounded by a high stone wall. The Tabernacle is an oval building, 150 × 250 ft., with an elliptical domed or "turtle-back" roof, 100 ft. high at the center. This roof is composed of wooden arch trusses, as shown in Engineering News of Oct. 5, 1895, the top chord of which carries the outer covering or roof, which is of tin roofing, while the lower chord carries the smooth turtle-back ceiling, the trusses being entirely concealed. The building will seat 12,000 persons, but its acoustic properties are wonderful, owing largely to the peculiar form of the ceiling. The Temple is a fine stone structure, 100 × 200 ft., with three towers at each end. It was commenced in 1853, but was not completed and dedicated until 1893. Its cost aggregated nearly $5,000,000, and it is said to be the costliest ecclesiastical structure in the United States, with the single exception of St. Patrick's Cathedral in New York city. It is an imposing structure, but does not in reality appear so large as it appears in the accompanying picture, a remark which will apply equally to the Tabernacle. The general dimensions of the Temple are as follows:

Length		200 ft. 0 ins.
Width		100 ft. 0 ins.
Height:		
Central west tower	204 ft.;	with spire, 219 ft. 0 ins.
Central east tower	210 ft.;	" " 222 ft. 6 ins.
Side west towers	182 ft.;	" " 194 ft. 0 ins.
Side east towers	188 ft.:	" " 200 ft. 0 ins.
Height to top of main walls		167 ft. 6 ins.
Thickness of walls, bottom		9 ft. 0 ins.
" " top		6 ft. 0 ins.
" buttresses		7 ft. 0 ins.

Business is dull now, and there is but little engineering work in progress. Several water power and electric power schemes are projected to utilize the water powers available in the mountain canyons, and two or three important ones are already in operation, notably those of the Pioneer Power Co. and the Big Cottonwood Power Co., noted in Engineering News, Oct. 1. It is not easy to see, however, that a sufficiently wide field is open for the application of the power when generated. On one hand it is stated that some of these projects are planned now so as to get control of the water rights, while the extremely low rates for machinery, supplies and labor are favorable to carrying on the work of construction. On the other hand it is argued that the promoters would hardly be likely to sink money in such plants without having some definite idea as to the application of the power to be generated. Irrigation works are somewhat numerous in this state, and one important enterprise—that of the Mount Nebo irrigation system—will shortly be described and illustrated in this journal. Mr. O. R. Young, the engineer for these works, has prepared a somewhat novel set of earthwork tables, which give closely approximate quantities for slopes read off on the clinometer. They are thus specially advantageous for preliminary estimates, and it is believed that they are the only tables of the kind which have been prepared.

City Engineer's Department; Salt Lake City.

The office of City Engineer was only created on April 1, 1890, Mr. A. F. Doremus, M. Am. Soc. C. E., being appointed to that position for a term of two years, and then reappointed. On Feb. 13, 1894, Mr. Doremus was appointed chairman of the Board of Public Works, and Capt. Willard Young was appointed City Engineer. Mr. Doremus resigned his position on the board on Aug. 8, 1896. Mr. F. C. Kelsey was appointed Assistant City Engineer on April 5, 1890, and served in that position until March 11, 1896, when he was appointed City Engineer (to succeed Captain Young), which position he now holds. It is only within these past six years that there has been a systematic surveying and monumenting of the streets and lots, this work having been inaugurated by Mr. Doremus. The main part of the city has now been most carefully surveyed, and the surveys have been plotted in beautiful shape in record books, strongly bound in canvas boards. In carrying out this work, a standard of length was first established, and a very substantial system of monumenting was adopted. The street monument used is a stone post set in concrete, and having its top (with the center mark) covered with a cap to protect it and afford easy access. These and other details will be given in a separate article. The engineer department has large and attractive offices in the City and County Building, and on the wall is an immense blueprint map of the city, together with a set of blueprint block plans of the city, showing by colors and symbols the paving, water mains, sewers, electric lights, street railways, contract work, etc., and being exceedingly convenient for reference. Adjoining the office is a very large fireproof vault for the records, drawings, etc.; a large table is provided so that the books or drawings can be consulted and examined without taking them out of the office. All the original field books are kept here. There is also on one side of the vault a long set of large shallow drawers for tracings, etc., which are all systematically arranged, indexed and labeled. A wedge-shaped cleat is attached to each side of each drawer, and a square stick extending across the drawer is slipped under these, so as to hold the tracings down and keep them from curling or from shifting about. Records of paving work and contracts, with prices of work are kept in a special book, with the style of construction drawn on one page, and the records and statement of cost on the opposite page.

THE CITY AND COUNTY BUILDING, SALT LAKE CITY.

The system adopted for lettering plans is specially interesting. All ordinary notes, explanations, etc., are written by hand, the Reinhardt style of lettering being adopted, but for large titles, etc., Ockerson's hand stamps, with ordinary printing type, set in a frame are used. The largest stamp will print a title 6 ins. long at one impression. A plain open type of letter is used, and for the smaller sizes a type as near as possible to the Reinhardt style is adopted. A special ink is used, being a printing ink with plenty of dryer in it. Great care is taken in the proper placing and printing of the titles, and very good work is done, with much greater rapidity than might be expected, while the saving in time over the hand lettering of large titles is very considerable. One boy, at $30 per month, does all this and looks after the type, ink, stamps, etc., and the result is that the work is done quicker and better than by an ordinary draftsman at higher salary, besides insuring greater uniformity. This plan was adopted partly on account of its efficiency, and partly on account of the difficulty in getting draftsmen who could do rapid plain lettering in large sizes.

The city has a considerable amount of asphalt paving, but it is hardly recognizable at first, on account of the dusty condition of the streets, the care of the streets being under the charge of a political non-technical office. The pavement laid with asphaltic sandstone mined at Santa Cruz and San Luis Obispo, Cal., is the best asphalt paving in the city, and some of it which has been in use for five years has cost very little for repairs. Some portions of the pavement laid with Utah asphalt are in first-class condition, while others are badly cracked and show signs of disintegration. This would appear to indicate that the material makes a good pavement if properly manipulated. The Salt Lake Stradamantic Asphalt Co. paved one intersection to introduce its material, which it called stradamantic asphalt, but the pavement was a failure, and the company failed to repair it when requested to do so. The following statement shows the amount, kind and cost of asphalt pavement contracted for up to the present time; the contract prices include grading, except in the case of the last contract for 1896; this contract was awarded on Aug. 25, 1896, and the work is to be completed by Nov. 1:

Year Laid.	Area. Sq. yds.	Asphalt.	Thickness. ins.	Concrete foundation. thickness.	Contract price. Per sq. yd.
1891	2,343	Cal. asphaltic sandstone...	2½	6-in.	$2.99
1891	1,100	Stradamantic asphalt	2	*4-in.	3.24
1892	14,989	Cal. asphaltic sandstone...	2½	6-in.	3.24
1892	2,871	Utah asphaltic limestone..	2	5-in.	2.90
1893	23,886	Utah asphaltic limestone..	2½	6-in.	2.79
1893	15,100	Cal. asphaltic sandstone...	2½	6-in.	2.97
1896	3,900	Utah asphaltic sandstone..	2½	6-in.	2.74

*Asphaltic cement concrete.

On several of the business streets, the gutters and sides of the street are paved with red sandstone, while asphalt is laid between the street-car tracks and from the outside of these tracks to the block paving. The street railway company paves its portion (along the tracks) by separate contracts from those for the rest of the street. In these business streets the irrigation water flows down the ordinary gutters, special covered crossings being provided at street intersections.

The water supply system of the city comprises some very heavy and interesting works, which will be described and illustrated in this journal shortly. One of the most important recent works is the sewage farm, for treating the sewage from the gravity outfall sewer described in Engineering News of Jan. 4, 1894. The sewage was first turned into the sewer and main ditch on July 11, 1896, on which date I had the pleasure of visiting the farm in company with Mr. Kelsey.

Railways.

There are several railways projected in the neighborhood of Salt Lake City, but most of them are short lines to mining districts. The most important of the projected lines is the Utah & California Ry., which is to give Salt Lake City direct communication with the coast towns of southern California, and thus avoid the present roundabout route over the Southern Pacific Ry. by way of Sacramento. The line will run south over the Frisco branch of the Union Pacific Ry. to Milford, 221 miles; will then follow about 125 miles of roadbed graded in 1890 by the Union Pacific Ry. (and which can be put in condition for about $500 per mile); and will then strike across the lower end of Nevada into California. The southern terminus is not yet definitely decided upon, but the line may make connection with the Atchison, Topeka & Santa Fe Ry. at Barstow, thus getting direct access to Los Angeles. The total distance from Salt Lake City to Los Angeles, by way of Barstow, will be about 803 miles, of which practically 488 miles are built. The distance by the present route is 1,225 miles. The line would open up a coal and iron ore district (magnetite and hematite ores), and pass through a district said to be rich in gold, silver and lead, giving a rail communication to the mining districts of Pioche, Bristol, De Lamar, etc. The maximum grade to the north is to be 79 ft. per mile, with the exception of short lengths of 106 ft. per mile, while going south the maximum grade will be 53 ft. The minimum curvature will be 8°, except for some 10° curves in getting over the edge of the Salt Lake basin. There will be very few bridges or trestles, and it is said that no very heavy work will be encountered, and that the line (including stations, water supply and shops) can be built for $14,000 per mile. Owing to present financial conditions the scheme is temporarily shelved, and all field parties have been called in, but representatives of the company have been in the east trying to negotiate for the necessary funds for carrying on the work. Mr. H. M. McCartney, of Salt Lake City, is the Chief Engineer. He is also Chief Engineer of the Salt Lake & Pacific Ry., which is intended to run southwest to the Dugway mountains, opening up a district rich in carbonate silver-lead ores and other minerals. It will cross the Sevier Desert, and will be mainly in desert country, with light and cheap construction, and maximum grades of 80 ft. per mile. All mining supplies and materials would be carried in, and water might also be hauled. Some of the mines already opened have been abandoned on account of the cost of teaming or the impracticability of teaming over a country where there is no water supply. It is not thought that this desert (which is a southern part of the Great American Desert) will ever be made available for cultivation, as there is no river available for a water supply and wells cost too much, except for irrigating fruit. Two lines of 100 miles in length have been surveyed, but further work remains in abeyance awaiting the improvement of financial conditions. The Rio Grande Western Ry. is proposing to build a line north from Provo to Park City, and to extend its Salina branch southwest to Richfield, Elsinore and Sevier, about 35 miles. The new Salt Lake & Mercur Ry. was described in Engineering News July 2, 1896. The Great Salt Lake & Hot Springs Ry., which is a steam dummy line, 15 miles long, has just completed an extension from Farmington to a new pleasure resort at Lagoon. The Chief Engineer is Mr. E. A. Vail.

STREET RAILWAY EASEMENT CURVES.

By Charles A. Alden, Steelton, Pa.

With the higher speeds and larger cars, which the advent of the electric railway brought in street railway work, the necessity of some sort of easement curve for the short radii required in street work very early became evident. The question as to its form has generally been considered as if the paths followed by all parts of the car were necessarily somewhat similar to the alinement of the track. This has led many engineers to believe that a three-centred curve was sufficient for practical purposes, besides being somewhat easier to design and calculate.

This assumption as to the path of the car is only true as to the small portion of the car which lies between the two axles or the center pins of a double-truck car. The parts of the car outside of this area describe rather peculiar paths, as is shown on the figures accompanying this article.

Fig. 1 is a case which the writer has seen repeated many times in the last few years. The curve is primarily designed to enable cars to pass each other on a double-track curve, but is also supposed to act as an easement. It will be noticed that there are four changes in the direction of rotation of the point A and also four abrupt changes in the rate of rotation of the point B.

It should be understood that the radii given for the short arcs in these paths are only given in order to convey an idea of the sharpness of curvature at these points, as these arcs would not be exactly circular, although nearly so.

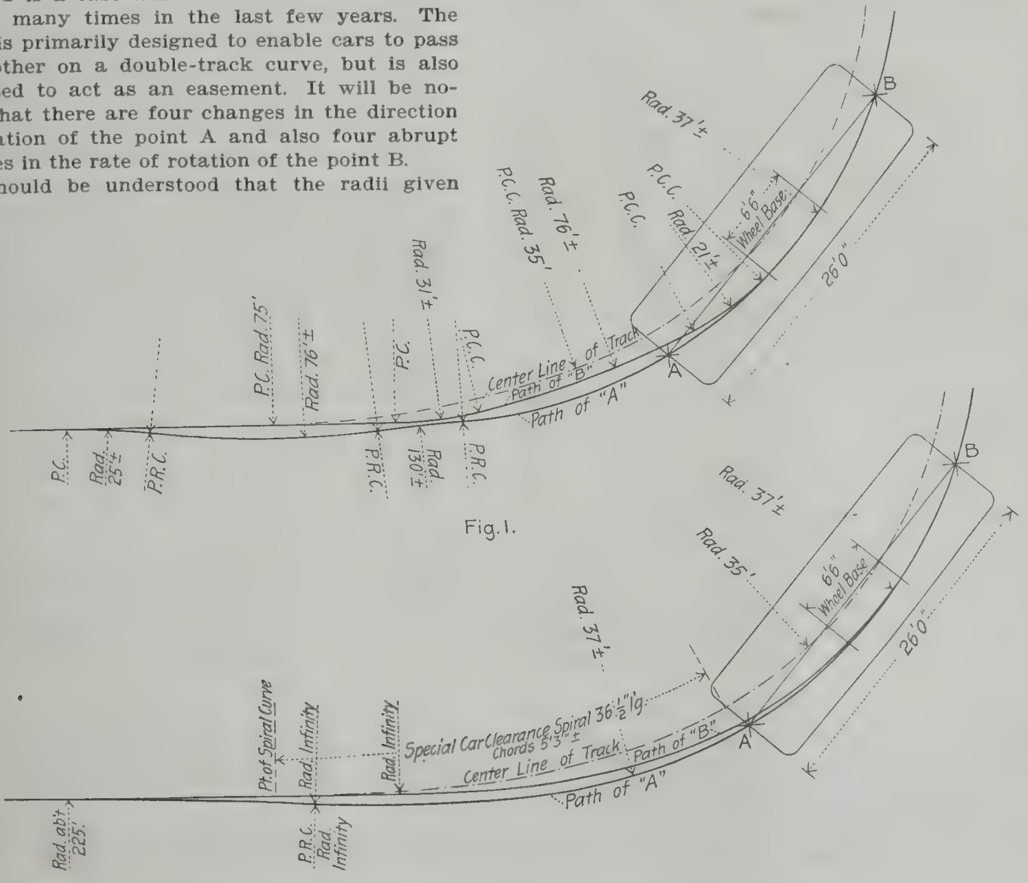


FIG. 1.—PATHS TRAVERSED BY POINTS AT ENDS OF A LONG ELECTRIC CAR IN PASSING ROUND A THREE-CENTERED CURVE.

FIG. 2.—PATHS TRAVERSED BY POINTS AT ENDS OF A LONG ELECTRIC CAR IN PASSING ROUND A CURVE HAVING SPIRALS AT ITS ENDS.

These changes of direction in the path of A will occur at any P. C. C. of a three-centred curve, if the first radius is sufficiently long to be of any use in preventing the jar of striking the P. C. of the curve. The sudden changes in the rate of rotation of the point B will be found to occur at every P. C. C. of a compound curve unless it is of the form of the railway spiral with chords of a length shorter than the wheelbase of the car.

Fig. 2 shows exactly the same main curve shown in Fig. 1, but connected with the tangent by a spiral of seven chords having the following radii: 300, 150, 100, 75, 60, 50 and 40. The "spiral" is somewhat forced on the last radius in order to keep the center of the curve in exactly the same position while at the same time maintaining the same car clearance. The track curve does not vary in position at the center of the spiral more than 4 ins. from that shown in Fig. 1.

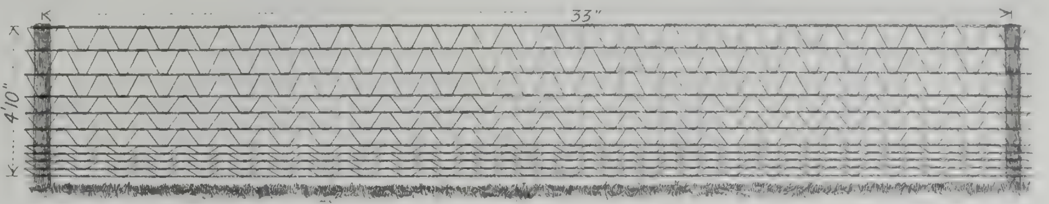
Note that there are but two changes in the direction of rotation of the point A. One of these is at the point where A leaves the tangent, from which there is a gradually decreasing curvature until it reaches the point of reverse curvature. From this point the curvature increases gradually until the point A attains its maximum rate of rotation parallel to the main curve. The rate of decrease and increase of curvature for both these arcs is somewhat less than that for the track curve. The point B also describes a curve with gradually increasing curvature until it reaches its maximum rate of rotation and follows the same path as A. The rate of increase of curvature would be somewhat greater than that of the track curve.

The car shown in these figures is by no means an extremely long car, as there are other cars known to the writer which are 30 ft. long, and others proposed which will be 38 ft. long and with only 6 ft. 6 in. wheelbase. The overhang of a double-truck car is nearly always as much as that shown in the figures. The sudden changes of motion shown in Fig. 1 exert a severe racking strain on the car framing which is particularly destructive to open cars as the connection between roof and floor framing is necessarily weak. The effect on the passengers is not pleasant, although this does not appeal so directly to the treasury of the railway.

The plan shown in Fig. 2 would cost for material just $12 more than Fig. 1, and would cost that much only for the most expensive track in use for surface roads.

The trouble involved in designing curves with spirals is very slight after adopting three or four spirals as standard suitable to the speeds of cars at the points in question. In fact, with proper formula, there is exactly the same number of operations required to solve for all the quantities that the constructing engineer needs, as there is to solve for similar quantities for a three-centred curve.

THE McMULLEN RAILWAY FENCE.



THE McMULLEN WIRE FENCE.

The growing favor with which wire fencing is being regarded by railway companies has resulted in bringing out a number of new designs of such fencing, and one of these (which was exhibited at the recent convention of the Roadmaster's Association of America) is shown herewith. The panel length, or distance between posts, is 33 ft. There are eleven horizontal wire cables, the top one composed of four No. 12 wires and the others of two No. 12 wires each. There are four lower spaces of 3¼ ins., then three of 6 ins., and three of 9 ins. The intermediate or binding wires are of No. 14 gage. This fence is manufactured by the McMullen Woven Wire Fence Co., 114 North Market St., Chicago, Ill., which also manufactures ordinary open mesh or woven wire fencing for railway and other purposes.

THE ROWAN STEAM STREET CAR MOTORS IN FRANCE

The combination steam motor cars of the Rowan system were first tried by the Paris Omnibus Co., during the Paris exhibition of 1889, four cars being used, and having a run of 1.55 miles in 10 minutes. At times each motor hauled a double-deck car seating 63 persons. After the exhibition the operation of this line ceased, but in October, 1890, the cars were put in service on the Pigalle-Trocadero line, for six months, and since September, 1891, they have been in service on the Auteuil-Boulogne line. The run of 1.86 miles is made in 12 to 15 minutes, including stops, and the three motors makes 122 trips per day, hauling a trail car on 38 trips. The motors are turned by switching on a Y at each terminus. The track is of standard gage. The following particulars are taken from an article in the "Revue Generale des Chemins de Fer."

There are six engines in operation, the two latest of which differ from the others in having double boilers. The car has an iron frame, the front end of which is carried by a four-wheel driving truck upon which is mounted the boiler (the engine and truck being detachable from the car), while the rear end is carried by a pony truck. The body of the car seats 22 persons, while 21 persons (paying a reduced fare) can stand on the two platforms, one of which is between the main body of the car and the engineman's compartment. The car is 30 ft. 6 ins. long, 6.56 ft. wide and 6.75 ft. high in the body. The distance from rear axle to center of truck is 18.6 ft. The engine consists of a vertical boiler (or two vertical boilers) mounted on a four-wheel driving truck, upon which rests the front end of the car, as already noted. The wheels are 25 ins. diameter, with a wheelbase of 5 ft. The frames are inside the wheels. The connection between the motor and car is effected by two vertical rollers at the back of the motor frame, between which slides a curved guide attached to the car frame. Side bearings are also provided, running in curved channel irons on the motor frame. To disconnect the motor it is only necessary to jack up the front end of the car until the guide is clear of the roller, then to raise the smokestack, disconnect the pipes leading to the water tank and condenser, remove the dashboard and run out the motor. The car body can thus be kept in service while the boilers or engines are being cleaned or inspected. The boiler is cylindrical, with rows of inclined water tubes passing through the upper part of the square firebox. The upper and lower parts of the shell are bolted together by outside flanges, so that they can be entirely separated for examination, which is done every six months. There are 131 tubes, 1.52 ins. diameter, with upset threaded ends screwed into the plates. The length between plates is 22.6 ins. The heating surface of the tubes is 95.01 sq. ft., and that of the firebox 17.43 sq. ft.; giving a total of 112.44 sq. ft., so that the evaporation is very rapid. The firebox is charged by means of small buckets instead of a shovel, each containing from 8 to 10 lbs. of coal. Three or four bucketsfull are thrown in, and this usually suffices for a round trip, but six extra buckets are carried for use on the road if necessary. The condenser is carried on the roof of the car. The weight of the motor is 121,000 lbs.

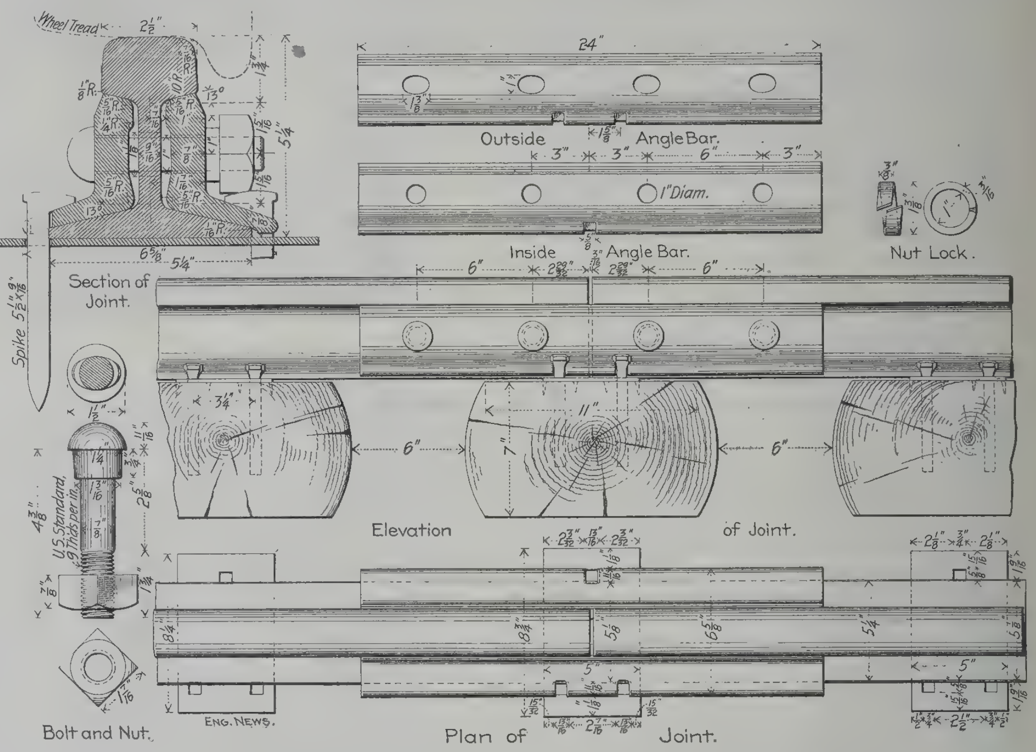


FIG. 1.—STANDARD TRACK WITH 85-LB. RAILS; DENVER & RIO GRANDE R. R.

The cylinders are horizontal, 6.6 × 13.6 ins., and drive the rear axle, which is cranked, the leading wheels being driven by coupling rods. The Winterthur valve gear is used, which resembles the Walschaert's gear. In the newer engines, the boiler has two vertical shells and fireboxes, connected by a horizontal shell of the same diameter. The rows of tubes diminish in diameter and pitch towards the top. The cylinders are inside, and slightly inclined. The valve gear is of the Stephenson link type.

The motors are fitted with brakes, operated by a treadle lever, which lever is also connected with a Lemoine brake, having belts to drums on the axle and shoes to the driving wheel tires. Trail cars have the brake mechanism coupled up to that of the motor car.

STANDARD TRACK AND THREE-RAIL SWITCH WORK; DENVER & RIO GRANDE R. R.

The Denver & Rio Grande R. R. began life as a narrow gage line laid with 30-lb. rails, but, as shown by the comparative sections of rails on this road, in our issue of Sept. 3, the weight of rail has steadily increased until now quite a considerable portion of the standard gage main line is laid with 85-lb. rails. This present standard type of track we illustrate herewith in Fig. 1, from blue prints furnished by Mr. M. H. Rogers, Chief Engineer.

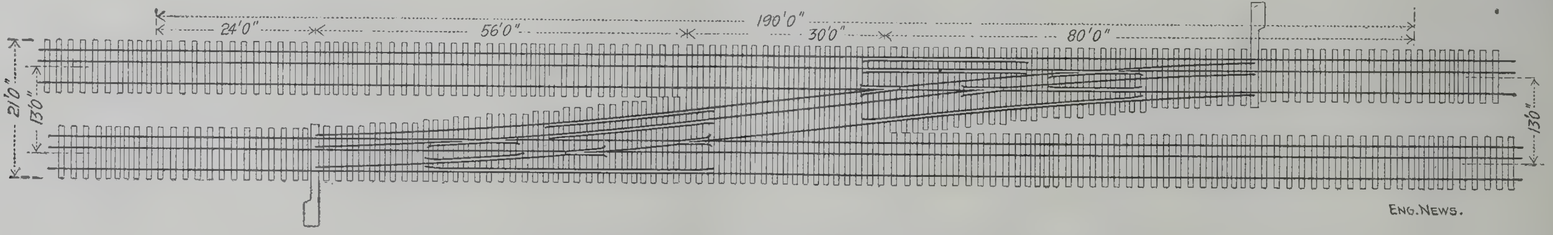

FIG. 2.—THREE-RAIL CROSSOVER; DENVER & RIO GRANDE R. R.

The rail is chefly noticeable for the roundness of its head, the top radius being 10 ins., with corners of 7-16-in. radius. The dimensions of this rail and the 85-lb. rail of the Am. Soc. C. E. section are given in the following table, and the weight of the steel of the D. & R. G. R. R. rail is taken at 10.204 lbs. for a section of 1 sq. in. one yard long:

The joint is of the supported type, with four-flanged Servis tie-plates on the joint and shoulder ties, these ties being 6 ins. apart in the clear. The the shoulder-ties are 5 × 8¼ ins. The rails are double spiked on the outside on each of these ties, the spikes being of the standard size, 5½ ins. long and 9-16-in. square. The angle bars are 24 ins. long, of heavy section in the web, the flanges being kept clear of the ties. They are of soft steel, have an area of 3.66 sq. ins., and weigh 47.6 lbs. per pair. The outer bar has oval holes, 1 × 1⅜ ins., and one spike slot; the inner bar has circular holes 1 in. diameter, and two spike slots, plates on the joint-tie are 5 × 8¾ ins.; those on the bolt holes in the rails being 1⅛ ins. diameter. The spike slots are ⅝ × 25-32 ins., with corners of ⅛-in. radius. Button-head bolts are used, ⅞-in. diameter, with oval necks 1¼ × ⅞ ins., and having nuts 1 7-16 ins. square and ⅞-in. thick. The nuts are put on the inside or gage side of the rail, with Verona nutlocks between the nut and angle bar. The bolts are 6 ins. c. to c. In laying track the expansion spacing at the joints is regulated as follows, according to the temperature:

102° F..........	1-16-in.	24° F..........	¼-in.
76° F..........	⅛-in.	— 2° F..........	5-16-in.
50° F. (normal)	3-16-in.	—28° F..........	⅜-in.

Dimensions of 85-lb. Rails.

" in base, per cent.	36.28	37

This road is notable for having a considerable mileage of three-rail track, extending from Denver to Pueblo and Leadville, so as to accommodate the passenger trains of standard gage and the trains of narrow gage cars of ore from the mining branches to the smelters at Pueblo. Some notes of this track have been given in the article on the D. & R. G. R. R. rails in our issue of Sept. 3, and in the transcontinental notes in our present issue. This arrangement of tracks makes the switch and turnout work somewhat complicated, and we illustrate in Figs. 2 and 3 a crossover and a turnout on the three-rail track. The crossover is for tracks 13 ft. apart c. to c., while for tracks 12 ft. c. to c. the only change is that the center distance between frogs is 22 ft. instead of 30 ft., making the total length over heel joints of switch rails 182 ft. instead of 190 ft. The turnout requires four guard rails, one of 45 ft., two of 26 ft. and one of 15 ft. in length, the flangeway for these being 2 ins. Stub switches are used, with 30 ft. switch rails, having 24 ft. of their length unspiked, the unspiked portion being connected by four tie rods and a head bridle rod, and conforming to a curve of 8° 26′ when thrown for the turnout. The main frog of the turnout shown is No. 8½ (angle 6° 44′), with a No. 10 frog for the narrow gage turnout rail and No. 1 or No. 2 double-point or crossing frog for the narrow gage main line rail, as shown by the diagram. There are 14 sawed ties for the moving portion of the switch rails; the headblock is of two pieces, 15 ft. and 4 ft. long, and beyond these headblocks are 40 timbers or ties. All the timbers are 7 × 9 ins., except the first two (headblock timbers) which are 9 × 12 ins.; the timbers aggregate 464 lin. ft., and 2,507 ft. B. M. The bill of timber is as follows:

1 piece	..15 ft. 0 ins. long.	3 pieces	..........11 ft. 6 ins.
1 "	.. 4 " 0 " "	2 "	..........12 " 0 "
4 pieces	.. 8 " 6 " "	3 "	..........12 " 6 "
5 "	.. 9 " 0 " "	3 "	..........13 " 0 "
3 "	.. 9 " 6 " "	3 "	..........13 " 6 "
3 "	..10 " 0 " "	2 "	..........14 " 0 "
4 "	..10 " 6 " "	2 "	..........14 " 6 "
3 "	..11 " 0 " "		

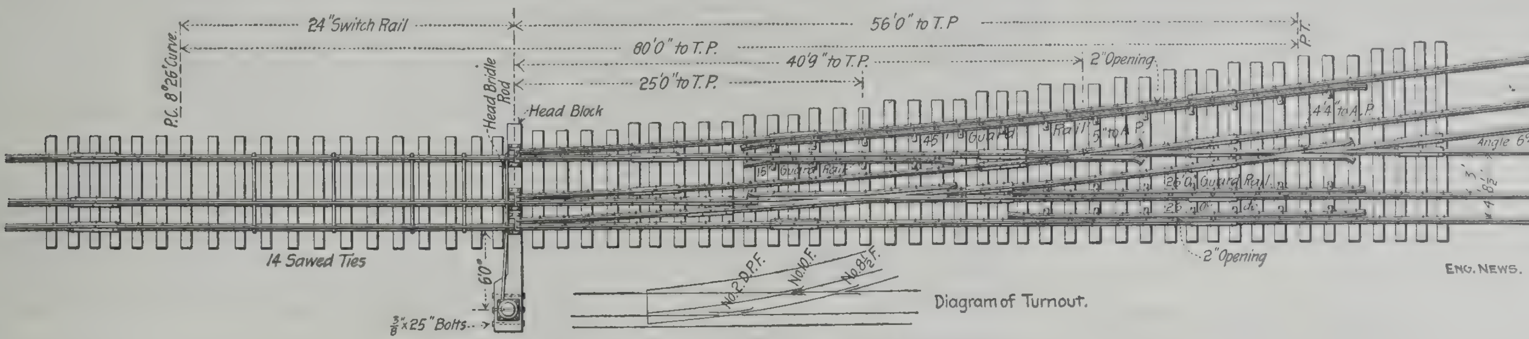

FIG. 3.—THREE-RAIL TURNOUT; DENVER & RIO GRANDE R. R.

PROGRESS IN THE EQUIPMENT OF CARS WITH AIR BRAKES AND AUTOMATIC COUPLERS.

In our review last week of the statistical report of the Interstate Commerce Commission, just issued, we gave particulars of the progress thus far made in the equipment of railway rolling stock with air brakes and automatic couplers. In addition to those figures we present a summary, abstracted from the report of the number of couplers of each special make in use, as reported to the Commission. The figures represent the total number of cars and locomotives of all classes, equipped with automatic couplers as reported to the Commission. The summary is as follows:

Kind of coupler.	Total cars equipped on June 30, 1895.	Kind of coupler.	Total cars equipped on June 30, 1895.
Janney	143,726	Standard	5,947
Gould	105,725	Thurmond	5,529
Chicago	22,964	Dowling	4,908
Trojan	17,646	Tower	2,873
M. C. B.	17,591	Pooley	2,505
Miller	17,123	Williams	2,251
Buckeye	14,938	American	2,035
Safford	8,642	California	1,980
Van Dorston	7,703	Mather	1,570
Smillie	7,606	Drexel	1,039
Hinson	6,636	Blocker	1,385
Missouri Pacific	1,036		

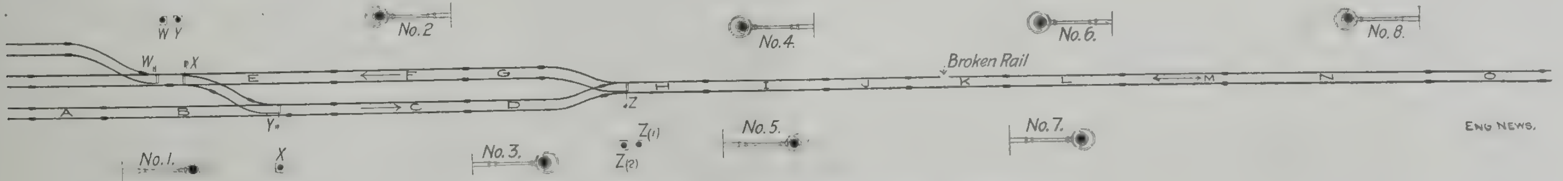
It is to be remembered that the Interstate Commerce Commission's statistics are made up from the reports furnished by railway companies, and on matters of this sort, of course, contain more or less errors. Thus the "M. C. B." couplers should be credited to the different makers, in some unknown percentage. The Miller couplers are, of course, all on passenger coaches. The automatic couplers of the link-and-pin type, which cut quite a figure in the Commission's statistics a few years ago, have, most of them, disappeared, but the Safford and Blocker couplers in the above list are of this type, and, of course, should not properly be reported.

In train brakes the "odd" brake equipment cuts a small figure. The totals given are as follows:

Kind.	Total equipment fit'd, June 30, '95.	Kind.	Total equipment fit'd. June 30, '95.
Westinghouse	345,836	Lansberg	601
New York	12,391	Haberkorn	27
Boyden	1,491	Unclassified	45

AN AUTOMATIC BLOCK SIGNAL SYSTEM FOR SINGLE TRACK RAILWAYS.

At the recent convention of the American Society of Railroad Superintendents a system of block signaling for single track lines, with automatic electric disk signals and overlapping blocks, was described by Mr. J. Schreuder, Chief Engineer of the Union Switch & Signal Co., and this system we illustrate herewith. The diagram plan represents a length of double and single track equipped with the signals, which are of the disk or banjo pattern, while the points of insulation are also marked.



AUTOMATIC BLOCK SIGNAL SYSTEM WITH OVERLAPPING BLOCKS.
Union Switch & Signal Co.

A train moving from A to O, the track being unoccupied and all switches propertly set, will find all signals clear. Signal No. 4, controlling movements from right to left, however, will be red, as it is, in part, controlled by the position of the switch Z, and will always show red while the switch is set for left to right movements.

The movement of a train from A to O, and the operation of the signals and indicators, will be as follows:

Entering A, the switch indicator Y is set to danger, thus giving warning at the crossover of the approach of a train. On entering B, indicator Y is still held red, while signal No. 1 is set to danger, thus protecting the rear of the train.

Leaving B, indicator Y is cleared, and on entering C indicator Z(2) shows red. This indicator is only operative when switch Z is set for left to right running.

Entering D, signal No. 3 is set to danger; as long as this section is occupied signal No. 1 remains red.

Entering H, signal No. 1 and indicator Z(2) are cleared, while indicator Z(1) is set to danger.

Entering I, signals No. 5 and No. 6 are set at danger. There is now no change until the train enters section K, when signal No. 3 and indicator Z(1) are cleared.

Entering L, signals No. 7 and No. 8 are set at danger.

Entering M, signal No. 6 is cleared.

Entering N, signal No. 5 is cleared.

Entering O, signal No. 7 remains at danger, while No. 8 is cleared. On leaving section O everything is returned to the normal position.

Now take a train running from right to left, with the switch Z set for the upper track, and signal No. 3 standing normally at danger. As the train enters section O it sets signal No. 7 at danger, and similarly sets signals No. 8 at N, No. 7 at M, and No. 6 at L. On entering section K, signals No. 7 and No. 8 are cleared, and at J the indicator Z(1) announces the approach of the train, signal No. 3 being already set to danger by position of switch Z.

Entering I, it sets signal No. 4 to danger, and at H clears signals No. 5 and No. 8, and continues to hold indicator Z(1) at danger.

At G, indicator Z(1) is cleared and indicators X and W are set to danger.

Entering F, it sets signal No. 2 to danger and still holds signal No. 4 red, while at E, signal No. 4 is cleared, but indicators X and W are still held red. Leaving E it clears signal No. 2 and indicators W and X.

A car on the fouling point of siding would set signal No. 2 and indicators W and X at danger; the siding switch being reversed the same danger signals would be displayed.

In setting the crossover, indicators W, X and Y and signal No. 1 would protect the movement.

A train moving from the siding to main line, single track, by way of switch Z, is protected by signals No. 4 and No. 1, set to danger by movement of switches, until it reaches C, where it sets indicator Z(2) to danger, and at D signal No. 3 is set to danger. When switches are set to their normal position all indicators are cleared except Z(2), and signals then protect the running as described in first movement.

In section K will be noticed a break in the rail. In practice the trainmen would be notified of such an occurrence by signals No. 6 and No. 5 being set to danger.

The function of the electric switch indicators, W, Y, X, Z(2) and Z(1), is to show trainmen working at a switch the condition of the track in both directions from the switch. That is, should a train be within the block in which the switch is located, the indicator will show red, thus giving notice that it would be unsafe to open switch. At each switch is placed a circuit shifting device, called a switchbox, which acts to set the signal to danger when switch is opened.

The following movements will show the protection afforded two trains traveling on the same track from opposite directions:

Train No. 1, on D, holds signals No. 3 and No. 1 at danger in rear, and signal No. 4 and indicator Z(2) ahead. Train No. 2 approaching from O, on reaching N will have signal No. 8 at danger in its rear and signals No. 7 and No. 5 in front. As train No. 1 is still in D, train No. 2 can proceed, and, on entering L will add signal No. 6 in its protection. Train No. 1 in entering H, clears signal No. 1 in rear, sets indicator Z(2) clear and Z(1) to danger, but as train No. 2, in L, is holding signal No. 5 at danger, train No. 1 is held by signal No. 5, and train No. 2 proceeds to signal No. 4 with the rear protection of signal No. 6. It will thus be seen that two trains cannot get together nearer than the distance of the overlap or the distance between two opposing signals on a single track.

This system is in use at the Pittsburg yard of the Allegheny Valley R. R.

DAMAGES FOR STREAM POLLUTION have been awarded against the Village of Saratoga Springs, N. Y., in one of the lower courts. The suit in question was one of several arising from the discharge of sewage in Kayaderosseras Creek. The decision holds that the sewage has rendered the stream flowing past the plaintiff's premises unfit for domestic use, that it has been rejected by domestic animals, and that it has caused the pollution of the atmosphere to such an extent during the warm months as to "seriously interfere with plaintiff's enjoyment of his right to live upon and occupy the said premises." Damages were ordered at the rate of $75 a year for six years or more, and it is averred that the plaintiff is entitled to an injunction to prevent the further pollution of the stream. The injunction is withheld for a year, but the plaintiff may apply to the court for continuing damages.

THE U. S. PATENT OFFICE, in the year ending June 30, 1896, received 45,645 applications for patents, reissues, designs, trademarks, etc. This is the largest number ever filed in any one year by nearly 2,000. The total receipts of the office for the fiscal year named were $1,307,090; and the total of receipts over expenditures now deposited in the U. S. Treasury to the credit of the Patent Office is $4,776,479.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; *6 months,* $2.50; *2 months,* $1.00; *Single copies,* 15 *cents. To all other countries in the Postal Union, add* $2.08 *per annum* (4 *cents per number*) *to above prices for postage. No club rates allowed. Mailing addresses may be changed at will by sending both old and new address. We shall be obliged if subscribers who fail to receive their papers promptly will notify us without delay. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number* 326 *means that subscription is paid to the 32d week (that is the issue of Aug 6) of the year* 1896; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: 20 *cents per line agate measure. Want notices, special rates, see page* 22. *Rates for standing advertisements sent on request. Changes to standing advertisements must be in hand on Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

The preservation of cross ties, and the question of the relative first cost and ultimate economy of treated and untreated ties, is a subject which comes up periodically for discussion. It seems, now, to be pretty evident that while engineers very generally recognize the practical and financial advantages of treated ties, the managers and executive officers of railways are, as a rule, able to realize only the extra first cost of the tie, and do not yet sufficiently appreciate the economies due to increased life of ties and the saving of labor in tie renewals, so that the engineers have a campaign of education to conduct before they can expect to bring about the general use of treated ties. From a detailed estimate prepared by a railway manager some months ago of the relative cost of southern pine ties the following summary is taken: For untreated ties, heart-pine or pitch-pine is usually specified, and as this is valuable for sawmill purposes, it is only the logs which are defective for such purposes which are available for ties. Thus ties of this wood cost about 55 to 70 cts. each, delivered at New York, and have a life of about 7 years in northern or 5 years in southern climates. The life is limited by rail wear and checking as well as by decay.

For treated ties, pitch pine is not suitable, as it would not absorb sufficient of the oil, and short-leaf pine is, therefore, used, which has a much more open grain. This timber is in little demand for sawmill purposes, and is, therefore, cheaper than the other, the cost at New York being about 48 to 54 cts. untreated, or 85 to 94 cts. treated, while the life is about 12 years.

Let us now take the average of these figures and see what is the actual cost per annum of each tie.

	Untreated tie.	Treated tie.
Average first cost, cts.	51	90
Average life, years	6	12
Annual interest charge on first cost (4%), cts.	2	3.6
Annual outlay for a sinking fund which will replace tie at end of its life (interest at 4%), cts.	7.7	5.6
Total cost per tie per annum, cts.	9.7	9.5

It will be seen from the above that the actual annual cost of the two ties, on a road which can borrow money at 4%, is practically the same. With interest at 6% the treated tie would be more expensive than the other by 0.36 cts. per annum. On roads where the above conditions prevail, therefore, the economy in the use of treated ties will arise in the economy of labor expended in track maintenance, rather than in the cost of the ties themselves. But on roads located in warm climates, where ordinary ties have a short life, or those located in regions so remote from a timber supply that ordinary ties are very expensive, there may also be a saving in the cost of the ties themselves. As a matter of fact the railway companies which have done most in the way of tie preservation are those which are located in the far South or on the treeless plains of the West. In view of the labor and expense of replacing ties in street railway tracks, it may well be expected that the street railway companies will soon find it to their advantage to adopt treated ties for their lines.

For some years past State Engineers and others interested in irrigation engineering and the general development of several of the far-Western states have been urging the U. S. Geological Survey to permanently mark upon the ground the elevations obtained in connection with its surveys. It was pointed out that without such permanent record of easy reference, much of the work performed by the survey was valueless, except for mere map-making purposes; and as the monuments used were of a very temporary character, all local traces of the survey were soon obliterated, and it was practically impossible to identify upon the ground the points and elevations marked upon the finely engraved maps which the Survey publishes. Prominent among the advocates of this much-needed reform was Mr. Elwood Mead, M. Am. Soc. C. E., State Engineer of Wyoming, and it is pleasing to note that the labors of himself and his associates are bearing fruit, and the order has been issued to begin the new plan of monumenting in the State of Wyoming. A former assistant of Mr. Mead, Mr. McFarlane, is now running a line of levels from the Union Pacific railway, at Cheyenne, as a base, to an undeveloped irrigation district in and about Laramie County. Iron monuments are to be set at the township corners and their exact elevation established and permanently marked upon these monuments upon brass plates. Another party has commenced a similar work in the Big Horn, and a portion of the Shoshone basins. The subject of the monumenting of the Government surveys was discussed in our issue of Feb. 27, 1896.

A question of engineering ethics which frequently comes to our attention relates to the credit which an engineer who actually carries out a piece of work should give to a predecessor who has been connected with it in its preliminary stages. The obvious answer is, give exactly the credit due by stating the facts in the case. There may be exceptional circumstances which appear to demand a variation from such a rule, but on the whole it seems to be the only right course to follow. The main reasons which might be urged for pursuing a contrary course are: (1) That where an engineer designs and carries out work with practically no reference to previous reports or plans, or even when following only their general outlines, there is no reason for sharing with another the credit for the work; and (2) that an engineer in relating how he stepped in where another had begun may seem to be exulting over his predecessor. The answer to such arguments is that giving due credit never hurts any one in the long run, even when given with more generosity than the bare facts require, and that the facts in these cases are seldom such that they cannot be stated without giving any real cause for offense.

A case in point has recently come up in connection with the water filtration plant at Lambertville, N. J., described in our issue of July 2, 1896. The writer of the article, Mr. Churchill Hungerford, stated that he was the engineer for the plant and made no reference to the connection of any other engineer with the work. Our attention having been called, later, to the fact that Mr. J. B. Rider had something to do with the work at the start we addressed him on the subject and submitted his reply to Mr. Hungerford, who in turn has stated his case and supplemented it by a letter from one of the directors of the Lambertville Water Co. The whole correspondence on the subject is too lengthy and of too little interest to our readers to warrant its publication. We therefore present instead the main facts in the case as we gathered them from the letters submitted as follows: Mr. Rider made a report recommending sand filter beds, prepared designs for them and set some stakes for cuts and fills. He prepared to take the contract for the work and Mr. Hungerford was, apparently, on the ground to serve as his assistant, when on account of financial conditions Mr. Rider was unable to close the contract. The water company then engaged Mr. Hungerford as engineer and constructed the beds on its own account.

The general plan recommended by Mr. Rider was followed, but it was varied in its details. Of the most important modifications both parties agree that Mr. Hungerford made some, and Mr. Rider claims that some had been previously discussed by him and the water company. Both engineers undoubtedly deserve credit for their connection with the work.

Promotors of ship canals and possible investors in canal securities would do well to closely study the experience of the builders of the Manchester ship canal. The Cotton Association of that city now admits that if those interested could have anticipated all the difficulties that have been encountered, it is safe to say, that the canal would never have been built. The cost was just about double the original estimates, though these seemed very reasonable at the time, and the chief object for which the canal was constructed, that of transferring the great cotton market from Liverpool to Manchester, has not been realized. But while the canal shares return no dividends to those who supplied the funds actually used in construction, the City of Manchester incidentally derives benefit from the reduction in port dues and railway rates caused by the competition of the canal and by the rapid increase in the direct shipment of goods of all kinds from Manchester. The two things made plain by this enterprise are that preliminary estimates of cost and revenue are often misleading, and that it is an exceedingly difficult task to attempt to change the location of a long and firmly established trade. The existence of the canal is doubtless indirectly beneficial to Manchester; but this benefit has cost the canal shareholders about $70,000,000, and they must find what profit and satisfaction they can in thus doing good to some one else. This is not, however, the class of dividends they were led to expect by the original promoters of the scheme; and it is still a question whether like results to Manchester might not have followed the investment of the same sum in other directions and for other purposes, with some profit to those who took the risks of the enterprise.

THE STREET RAILWAY TRACK OF THE FUTURE.

Ever since the electric motor began to displace the horse as a motor for street cars, the managers of street railways have been engaged upon the problem of how to make a durable track, and in their study of it have expended sums reaching into millions of dollars. The old-fashioned horse cars cheerfully bounced along over the old flat rail laid on a stringer; and at the speeds at which they ran, the rough joints and the rattle and noise of the car as it passed over them were endurable. The advent of the electric car sent this type of rail out of use; it had already been discarded in progressive cities. But no one in the early days of electric traction dreamed of making a track which should exceed that of any steam railway in strength and stiffness. The old flat rail, with no pretence to longitudinal stiffness, had done duty, after a sort, so long, that a railway track with light ties, spaced rather far apart, and with rails of 50 to 60 lbs. per yd. was supposed to be ample for the heaviest street car traffic. But there were several things that were not taken into account. The first of these was the weight of the motor, resting directly upon the axles, and producing a hammer blow at every joint; the second was the high speed of electric cars, and the third was their great weight compared with the weight of horse cars. The combined effect of these factors was to make life a burden for the engineer responsible for track maintenance on electric railways. It was seen very soon that an electric railway required a heavier track than that above described, and the laying of girder rails was begun. The depth of these went from 5 ins. up to 6 ins., 7 ins., even to 10 ins., and the weight was proportionally increased. Of course with every increase in depth of rail an increased depth of foundation became necessary, which meant more excavation and placed the ties further underground. The net result is that the track of a street railway, which, in the old horse-car days, was a very light and inexpensive structure, is nowadays an exceedingly heavy and costly construction; and notwithstanding this, proves by no means so durable as was hoped when the heavy girder rails were first introduced

It is difficult to understand why electric cars should be so severe on the track, and especially upon the rail joints. This is usually ascribed to the electric motors, which were formerly mounted directly on the axles. Nowadays it is customary to support as much of the weight of the motor as is practicable from the truck frame; but with the increase in size of electric motors there is still complaint that the rail-ends are pounded down. Why should an electric car be more severe on the rails than a steam locomotive? Take, for example, a modern high-speed steam locomotive for heavy service. There is the driving wheel, 6 ft. or more in diameter, the weight of half the driving axle, and one eccentric, the weight of the axle-box and part of the spring, and finally the weight of the parts attached to the wheel, which, in case of the main driver are the crank-pin, counterbalance weight, half the weight of the parallel rod and more than half the weight of the connecting rod. When we have summed up all these weights, we find a total load on the rail not supported by springs which may equal or exceed the load that is not spring-supported on an electric car-wheel tread. Further the electric car may run at an average speed of 8 or 10 miles per hour, while the locomotive averages three or four times this; why, then, should not the locomotive be more severe upon the tracks than the electric car? Again, it is to be remembered that the cable railways also experience more or less trouble with their track-joints, though not as much as the electric lines. It would appear from this that the conditions under which street railway track is laid and maintained, may have something to do with the joint difficulties. Perhaps the fact that on a railway in a paved street the joints are let alone until their condition becomes so bad as to compel the removal of the paving to make repairs, has something to do with the troubles experienced. On steam railway lines, as is well known, the way to keep track in good condition is to constantly take the "stitch in time" that saves nine.

A very good proof of the serious nature of the joint problem on street railways is furnished by the radical treatment that has been accorded to it. The possibility of the use of continuous rails on steam railways was broached years ago; but it remained for the street railways to actually test the idea and prove its practicability.

At present there are in use in this country from 150 to 200 miles of street railway track, the joints of which have been all welded, either by the electrical or the "cast-welding" system, so that the rails are actually continuous. As to the success of this system, the testimony is rather conflicting; but the fact appears to be that the difficulties encountered have been no more serious than might naturally be expected to accompany so novel a departure from usual practice. The cast-welding system promises to supersede the electric welding system, according to our best information, because it produces as good or better results, at a less cost. Unless some further trouble should develop or those already found should prove more serious than they thus far have done, it seems quite probable that the street railway track of the future will have a continuous rail, at least wherever it is laid in paved streets.

Turning now to the foundation on which the rail rests, we find that the heavy punishment to which street railway track is subjected, is made evident here as well as at the rail joints. With heavier rails have come larger ties, more closely spaced, and of late there is a growing tendency toward the use of concrete in foundation work. All this means heavy expense; and it is a serious question whether the street railways of the country are at the present time getting the service from what we may call the sub-structure of their track that they should receive for the money they have expended upon it.

It is true in this department of engineering as in many another, that progress is in the nature of an evolution. The present street railway track has been evolved from the tracks of the steam railways. In the field of organic evolution we often see a bodily structure with members which no longer serve a useful purpose, but are traces of the structure of some ancestral race. In a similar way it is at least possible that in the evolution of the street railway track from that of the steam railway certain features have been retained which no longer serve their original purpose.

Let us see what qualities the ideal rail support on a street railway should possess. Its office, of course, is to spread the weight which it carries over a sufficiently large area to support the load without settlement. Whether in addition to this it should have a certain elasticity is a question which is undecided. There is, indeed, a general belief that the rail must have an elastic support; but it is unquestionable that the necessity for the elasticity arises mainly from the imperfections and inequalities in the foundation. Thus on cable railways the rails have been carried directly on the cast-iron yokes and no harm has resulted to either rails or rolling stock.

On a steam railway line the rail supports must fill several other requirements. They must keep the rails to gage; they must hold them from canting; they must permit the rails to be readily fastened to them; they must allow of quick repair and replacement in case of derailment or other accident injuring the permanent way. Now, all these requirements obtain in much less degree if at all, on a railway in a paved street. The paving itself holds the rails to gage and keeps them from canting, and the necessity for secure anchoring of the rail to the foundation is merely to prevent any hammering action taking place. Further, a derailment or other accident in a paved street cannot injure the rail supports.

We may now ask the question, why do we use cross-ties to support the rails of a street railway? Is it because they form the best and most economical support that could be devised, or is it, perhaps, because cross-ties have been used for rail supports almost universally since the first use of the railway? Is it not at least possible that a longitudinal system of rail supports for our street railways might prove more economical and durable, and reduce the cost and difficulty of track repairs? Again, is it necessary to bury such a large amount of wood beneath the pavement of a street railway as we do at present? Decay begins in it, we know, before it has been long in place; and with decay, settlement is inevitable, and this settlement will be by no means uniform. A rail in bad surface, and the entry of water and frost to the track foundation are the certain result.

In view of these defects of the cross-tie system of rail supports on street railways it is worth while asking whether we do well to adhere to it. Cannot a system of longitudinal foundations be designed which will give a continuous support to the rail, and which will fill all requirements better than the present system. Why not lay along the line of each rail a solid foundation of width sufficient to carry the required load without settlement, and either lay the rail directly upon it, or else, if some elasticity is found to be essential, interpose a stringer of wood as light as will give the required cushioning effect. In European practice it is very common to lay girder rails directly upon the concrete foundation of the street.

The first cost of such a system of rail supports would, perhaps, be a little greater than that of the present cross-tie system; but it seems probable that the reduced cost of track maintenance would much more than offset this. It will be apparent at once that with such a system repairs could be made on one rail of the track, or its supports, without at all disturbing the other and without removing the pavement at the center of the track.

If the street railway track of the future is to be made on the present system of cross-tie supports, it will only be because that meets the practical requirements better than any other. It is because the burying of a nearly continuous pavement of perishable and rapidly decaying wood beneath the tracks of a street railway appears to us to be an anomaly, that we have thought it wise to call attention to it, and to suggest the possibility of a better system. We know that in the process of organic evolution the organs which are inherited from former generations, but which are rendered useless by change of environment, continue for a time, and then gradually disappear. So in the case of the street railway tracks, if the system of cross-tie supports is a mere inheritance from earlier railway practice, we may expect to see it gradually disappear and something better will take its place.

LETTERS TO THE EDITOR.

Operating Steam Pumps without Oil in the Steam Cylinders.

Sir: We have recently noticed an article in your paper in regard to steam pumps operating without oil in their steam cylinders, in which credit was given to one of the manufacturers for having been the first and only company to adopt this practice. The machines referred to were very recently constructed and tested. It will doubtless be a matter of general interest to know that the Deane Steam Pump Co., of Holyoke, Mass., have built several hundred machines during the past two or three years expressly for operating without any oil in the steam cylinders. The pumps have been operating successfully and a large number of users report their operation as entirely satisfactory. The pumps referred to are all of them horizontal machines of the duplex type. Yours truly.

The Deane Steam Pump Co.
L. E. Bellows, General Manager.
Holyoke, Mass., Oct. 16, 1896.

Credit for the Johnson Electric Lighting Plant.

Sir: We have read with considerable interest your account of the electric lighting plant at Johnson, Vt., in your issue of Oct. 8. This plant was laid out by our Mr. Almon and it was on his suggestion that incandescent lamps were used rather than arc. We were the contractors for the entire electrical equipment and would have been glad to have had some mention in your article. We have also put in similar plants in Morrisville, Northfield, Bethel and Montpelier, all of which will show up very well in income and operating expenses. Very truly yours.

Almon, Sargent & Conant.
106 Equitable Building, Boston, Mass.

(Our apologies are tendered for the omission. It is the established custom of this journal to give full credit to both engineers and contractors in the description of any piece of engineering work. It was an oversight that it was not done in the above case.—Ed.)

The Weight of the Park Row Building.

Sir: In your issue of Oct. 8, 1896, in speaking of the Park Row Building in your editorial column, you say:

> "Probably the entire weight of the building when completed and occupied is not less than three times the weight of the steel in its framework, or a total of 18,000 tons."

The estimated total weights are as follows:

Weight of building	56,200	tons.
Weight of steel	9,000	"
Total	65,200	"

Yours very truly,
Nathaniel Roberts, M. Am. Soc. C. E.
Jersey City, N. J., Oct. 12, 1896.

(We thank our correspondent for the correction. Our comparison of the weight of the steel framework and the weight of the structure was really only a guess, and was purposely placed at the minimum which we thought possible, and a "slip of the pen" made the figures even less than they should have been. But the correct figures for the weight of the structure given by Mr. Roberts make still more forcible the point which we desired to make, viz.: the immense mass and weight of such a structure compared with the force which the most severe windstorm could exert against it. —Ed.)

Deep Borings for Foundations in New York City.

Sir: It may be of interest to record that a depth of 115 ft. was reached by boring on the site of the Tombs, without reaching rock. Boring was discontinued at this depth, because piling will be used in the foundations of the new prison, and we found satisfactory material for this purpose.

Another hole was driven to 90 ft., and discontinued, no rock being reached, while two others were bored to a depth of 80 ft., and were stopped by the rock. This shows the varying levels of the gneiss rock formation.

The bed of the old pond which existed formerly at this place was reached at from 30 to 40 ft., peat and other vegetable matter being washed up.

The material throughout in all test holes was gravel of a varying coarseness and sand. Particles of the old timber footings of the present prison were met with and washed up, having been cut by the pipe, and the old pine was as fresh as the day it was put in, 60 or 70 years ago.

The depth at which rock was struck in the latter holes (namely 80 ft.), corresponds very closely with the rock level met with in the borings taken not 100 ft. away, on Elm street by Mr. W. B. Parsons, Chief Engineer of the Rapid Transit Commission. This was I think about 84 ft.

Very truly yours,
F. S. Williamson, M. Am. Soc., C. E.
(Engineer to the Architects, Messrs. Withers & Dickson.)
Broadway, New York, Oct. 5, 1896.

Plants for Long Distance Power Transmission.—Correction.

Sir: Referring to your issue of Oct. 8, I find two typographical errors on page 231, in the list of plants in Dr. Duncan's address on "The Present Status of the Distribution and Transmission of Electric Energy." The line-voltage of the Pomona and San Bernardino plant is given as 1,000 volts, whereas it should be 10,000 volts. Again, the plant at Rome is credited with a distance of 188 miles, instead of 18.8 miles. When these corrections are made, the Pomona plant is seen to occupy its true position as the first plant in this country to use such a high pressure as 10,000 volts, and also to transmit power over so great a distance. The Pomona plant owed its origin directly to the success of the experimental plant temporarily put up between Lauffen and Frankfort, and was watched with great interest by engineers and investors as being the first plant in any country to commercially use such a high voltage over such a great distance. The construction and operation of this plant, of which I was engineer in charge, is fully described in the Transactions of the American Institute of Electrical Engineers in my paper on "Long Distance Transmission at 10,000 Volts." read in June, 1895.

Yours truly,
G. H. Winslow.
Lewis Block, Pittsburg, Pa., Oct. 12, 1896.

(The errors referred to were in the copy of Dr. Duncan's paper, furnished to us for reprinting. We may note also that copies of the paper by Mr. Winslow were printed separately from the Electrical Engineers' "Transactions," and we presume can be obtained by any of our readers by addressing him as above.—Ed.)

A Neat Pamphlet Filing Case.

Sir: I send in this mail a pamphlet case for engineers which I designed for my own use and had manufactured by Mr. C. A. Brackett, of this city. It is the result of considerable study, after failing to find anything in the market to suit my ideas. For municipal reports, and as a temporary binder for the Journal, it is just what I want at a moderate price, $3 a dozen, and may be desired by other engineers. Yours truly, Edward P. Adams.
53 State St., Boston, Mass., Oct. 8, 1896.

(The case sent by Mr. Adams is a neat pasteboard box, 7×9⅞×2¾ ins., inside measurement, designed to stand on end, with a flap back cover, opening up, and shutting into the case. The edges are reinforced, and the cover is entirely covered with black cloth. The cover forms the back of the case, and has printed on it in gilt "Engineering and Municipal Reports and Papers," and below, "Vol.," with an enclosed space for the number. A gummed label accompanies the case, which can be used for the volume number, or any other brief designation desired. The construction of the case renders it as nearly dust proof as possible. A number of different styles of cases are made by the Library Bureau, of 280 Broadway, New York, and with offices in Boston, Philadelphia, Chicago and St. Louis. Some of these cases are cheaper, and some more expensive, than the one described above. Most of the cases are made of wood, and thus are more durable than the one sent by Mr. Adams.

We have used for some years past filing cases about 8×10½×4 ins. of ordinary pasteboard, made up with black cloth, and having white paper pasted over the whole back, for titles. These boxes have no covers, and cost only some 5 cts. apiece. Similar ones can be obtained, we suppose, from any manufacturer of paper boxes.—Ed.)

Railway Commissions and the Issue of Stock and Bonds.

Sir: I read with much interest in Engineering News of Sept. 24 your notice and editorial comment on the late hearing of the Maritime Coast Company's application for the approval by the Massachusetts Railway and Harbor Commission of $6,000,000 stock and $6,000,000 bonds.

Your remark that Massachusetts is far in advance of other states in her laws regulating the issue of stocks and the marketing of bonds, while perhaps correct, should have included a notice of the Texas Stock and Bond Law of 1892, which antedates the Massachusetts law by two years, and which, judging by your synopsis of the proceedings referred to, seems to be identical in intention and effect. Texas has been more than generous to railway corporations during the past 25 years, and yet has incurred the pretended ill will of interested promoters and anti-promoters on all sides for her simple and statesmanlike regulation of the issue of bonds by both municipal and railway corporations. Permit me to refer you to your appreciative review of the operation of the latter laws in your issues of March 7, 1895, and April 23, of this year.

Just as ever, opinions depend very greatly on whose ox is being gored. I dare say that the Massachusetts folk consider their law a patriotic advance in statemanship, and yet from that same neighborhood has come the cry against "legislation inimical to capital," which has been alleged, without the slightest foundation in fact, against the fair name of our state.

It is gratifying to see that technical papers of your standing are taking the just position in the public interest which your remarks indicate. "Engineering" takes the same view of the question, and particularly as it relates to our state. The subject was discussed at length in the issue of Feb. 14 of the current year.

Yours respectfully, C. Corner,
Assoc. M. Inst. C. E., Assoc. M. Am. Soc. C. E., Expert Civil Engineer R. R. Com. of Texas.
Austin, Tex., Oct. 3, 1896.

(We owe our apologies to the Railroad Commission of Texas, for our omission to include that state with Massachusetts in the list of those seeking to reform past methods in the issue of stocks and bonds. Our editorial of March 7, 1895, treating of the Texas law and referred to by Mr. Corner, plainly sets forth our position upon the general question.—Ed.)

Experiments on Pumping from Artesian Wells at San Jacinto, Cal.

Sir: The writer was engaged during the winter of 1896 in the construction of a water system at San Jacinto, Cal. The supply was taken from three 7-in. artesian wells, located in the artesian belt which extends from near the mouth of the San Jacinto River canyon northwesterly a distance of several miles. The deepest well was 350 ft. and pierced alternate layers of clay, gravel and sand. The wells were cased with two thicknesses of riveted pipe, and the pipe was cut after the fashion of the region, in all water bearing sand, by a series of gashes, ⅛ to ¼-in. wide by 8 to 12-in. long, four in a ring, and the rings 12 to 16 ins. c. to c. The total thickness of water bearing sand in which the pipe was cut was about 170 ft. in the three wells.

The pump installed was a compound, duplex Worthington, with 12-in. plungers. The wells were about 50 ft. apart, each having a 6-in. suction pipe lowered into it about 30-ft. below the pump, all three being connected to a 10-in. suction main from the pump. A vacuum gage was attached to the vacuum chamber near the pump. At the time the pump was started the water would rise about 5 ft. above the pump and the three wells flowed at the ground surface about 50 gallons per minute. Readings were taken simultaneously of the vacuum gage and the speed of the pump and plotted after adding the head of water above the pump.

The result shows that the yield increased very nearly in proportion to the depth to which the water was lowered below level at rest, until the limit of suction was approached. A similar result was obtained with a centrifugal pump on a single well. The yield of the three wells was about 1,100 gallons per minute, as a maximum, with suction about 23 ft. below the pump.

The effect on nearby wells was noted as follows: A well 200 ft. away was lowered 3.1 ft. after five hours' pumping, the pump taking water 22 ft. by gage. A well 1,800 ft. away, across the drainage lines, fell about 0.1 ft. in one hour and 0.45 ft. in a little over three hours, and the greatest noted difference was 1 ft. after four hours' pumping. A well 700 ft. away, up stream, fell 1.7 ft. after five hours' pumping. A well 3,600 ft. away showed a decrease of flow in about five hours after the pump started, but no measurements were made.

Apparently the water pressure was lowered over a large area and the water slope to the well was very flat. After a day's run the water would stand about 3 ft. lower than at the start, the same as the amount of fall in a well 200 ft. away, and the conclusion reached was that the flow was limited, not by lack of water in the ground, but by want of sufficient entrance area into the pipes or by a clogging by sand near them. A twelve-hours' stop would bring the water back to its former level, save that the general level was falling about 0.5 ft. each month.

E. F. Tabor.
Escondido, Cal., Sept. 30, 1896.

A Schedule for Engineers' Charges.

Sir: I have read with interest the recent discussion concerning "cheap engineers," in your paper, and not wishing to lower the profession by cutting prices below what they should be, I would be glad to see a schedule of prices for some of the more common work which an engineer might be called upon to do, in a city of 7,000 inhabitants.

What would be a fair salary for city engineer in such a town? Sewer work and paving are just commencing. About what is the charge for laying out new additions, for running sidewalk grades and for surveying lots?

What per cent is usually charged for designing and superintending a system of sewers? What on masonry and steel bridges?

What is it worth to design a grade system for a town covering 2 sq. miles of territory with the blocks about 300 ft. square? The town is slightly rolling, with a stream through the center about 20 to 50 ft. below the land on either side.

If you will kindly answer these questions you will confer a great favor upon me, and doubtless upon many other young engineers, who, though they are competent to handle the work they undertake, often do it too cheaply simply because they do not know how much to charge for it.

Very respectfully,
———, Iowa, Oct. 3, 1896. O. E.

(Our correspondent's query is certainly a pertinent one. If cutting prices below what they should be is to be condemned by the profession, it is proper to inquire what prices should be asked for engineering work. There is no schedule of fees in general use by engineers, and the great difference in conditions between the engineer working in a small country town and the engineer working in a large city make the preparation of a schedule that would be of general application difficult or impossible.

In general the engineer in fixing a price for his work should consider two things. First, what is it actually worth to the party for whom it is done? The answer to this question will fix the maximum price that could be asked for the work. Second, what does the work actually cost the engineer, in time, expenses, tools, assistance, etc.? This should fix the minimum. Of course the answer to both these questions will vary greatly in different parts of the country, in places of widely varying population, or when the same piece of work is concerned, the question would be answered differently by engineers of varying experience, reputation and commercial push. If any of our readers can furnish answers which will better meet the needs of our correspondent, we shall be pleased to hear from them.—Ed.)

The Sewerage and Sewage Disposal Systems of Plainfield, N. J.

Sir: Referring to the article entitled "The Sewerage and Sewage Disposal Systems of Plainfield, N. J.," in your issue of Sept. 10, may I ask you or some of your readers the following questions:

(1) If "self-cleansing" means to carry off all solid matter which may enter sewers; is a grade of 1 in 1,200 for a 24-in. sewer, 1 in 900 for an 18-in. sewer, etc., self-cleansing? (2) Are not 6-in. branches for house connections better practice than 4-in. branches? (3) Are not the distances between the manholes, for the size and grade of sewers mentioned, too great?

Being familiar only with the combined system of sewers, the grades and distances between manholes on such small sewers appear strange to me.

Respectfully yours,
South Norwalk, Conn., Oct. 5, 1896. B.

(Familiarity with the combined system, only, doubtless accounts largely for the raising of the above questions, as our correspondent himself suggests. It is explained in the articles that the minimum grades adopted for main sewers were chosen in order to serve as large an area by gravity as possible. The grades were not selected arbitrarily and numerous flush tanks have been provided on the system. To put it strongly, the only reason for making ordinary house connections larger than 4-ins. is to give more leeway for careless servants and householders in the use of the sewerage system for the disposal of garbage, old clothes and waste metal. While larger house connections lessen the danger of stoppages by such matter they increase the deposits of organic matter by reducing the depth of flow in the sewer. Some engineers prefer 6-in. house connections, and a compromise is sometimes made at 5 ins.

The distance between manholes is given in the article as, in general, 400 to 500 ft. on mains and 700 ft. on laterals, with lampholes 200 to 300 ft. apart between the manholes on laterals, but with the important statement that manholes are placed at all junctions, changes of grade and alinement. In a separate sanitary sewerage system, properly designed in other particulars, it would seem that manholes placed as at Plainfield ought to be ample. There should be practically no deposits of organic matter and no foreign matter of sufficient size to make a stoppage should ever reach the sewer. As the stoppages must almost inevitably come from the houses, one advantage in having the house connections small is that it is then possible to determine who is responsible for stoppages, and provide and inflict a punishment to fit the crime.—Ed.)

◆

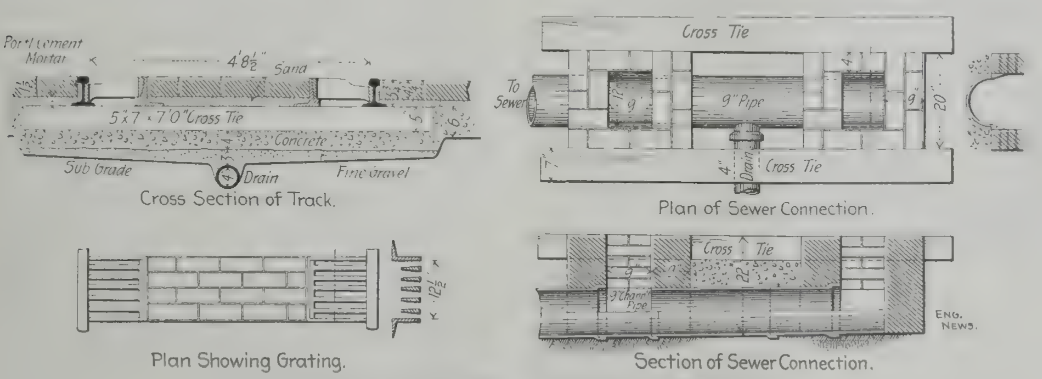
Hydrographic Surveys on the Outer Bar of Brunswick, Ga

Sir: In your issue of Oct. 1 there appears an article entitled "An Experiment in Dredging with Dynamite," in which I am quoted as "an engineer employed by Mr. Goodyear" in such a way as might give the inference that the results of my investigations on Brunswick Bar were on that account prejudiced in favor of the contractor. It appears also that the conclusions reached in the article referred to are the results of an investigation of only a part of the facts. It seems to me, therefore, that it is due to your readers, who I may presume are largely the civil engineers of this country, that you should publish the other side of this matter, and I therefore send you herewith a copy of my report on this subject with the hope that you will deem it of sufficient interest to your readers to publish it in full.

I would also beg to remind you that when this matter was before the River and Harbor Committee during the last session of Congress in which Captain F. V. Abbot was present and attempted to defend the report of the Board against adverse criticisms, it was the unanimous vote of the committee to ask the Honorable Secretary of War to reconvene the Board for the purpose of reconsidering its conclusions. It would, therefore, seem evident that your conclusions in this matter are not the result of a full investigation of all the facts. Very respectfully,

Galveston, Tex., Oct. 6, 1896. H. C. Ripley.

(We certainly did not intend to convey the impression that Mr. Ripley's survey and report on the depth of water on the Brunswick Bar was prejudiced in favor of the contractor. Nor did we intend to enter at all into the differences between the survey made by the Board of Engineers and that made by Mr. Ripley. Our conclusions as stated in the article were reached from a careful examination of a large mass of papers and documents furnished to us by Mr. Goodyear. If there are other facts more favorable to his process than those which he furnished us, we shall be pleased to have them presented to us.



Cross Section of Track.

Plan Showing Grating.

Plan of Sewer Connection.

Section of Sewer Connection.

TRACK DRAINS FOR STREET RAILWAYS; RICHMOND, IND.

The report of the Board of Engineers which made the survey of the bar and the report of Mr. Ripley upon his own survey and in criticism of the methods and results of the Board are very interesting documents but are, we regret to say, too long for reprinting in our columns. We advise any of our readers interested in hydrographic surveying, however, to secure copies of these reports, which we presume they can obtain by addressing Mr. Ripley as above, or Col. C. P. Goodyear, Brunswick, Ga. We may remark, as a matter of interest, that Mr. Ripley enumerates eight common sources of error in making soundings, and discusses the influence of each in the case under consideration.—Ed.)

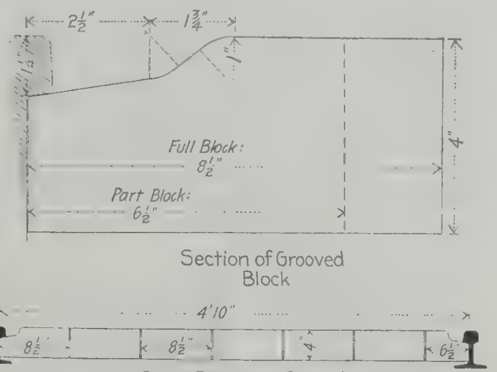
◆

A VITRIFIED BRICK PAVEMENT, on McDonough St., in Brooklyn, is to be torn up and replaced by asphalt, in response to continued complaint of the great noise resulting from traffic over this particular street pavement. Other streets in Brooklyn are paved in a similar manner, but are used without the peculiar "roaring sound" complained of by the residents of McDonough St. As these pavements, we understand, are laid on concrete with a sand cushion between the concrete and the brick, there seems to be no evident cause for the noisy quality objected to. It would be interesting to note whether a similar cause of complaint has been found in other cities and we would be pleased to hear from readers having any such experience. Cheapness, smoothness and a practically noiseless roadway, as compared with stone blocks, are the chief advantages claimed for vitrified brick pavements; and for use in thickly-built-up cities the third claim is a very important one.

◆

PAVING ALONG STREET RAILWAY TRACKS.

The method of paving a street at Cortland, N. Y., so as to leave a flangeway for the wheels of electric cars running on a track laid with T-rails, was shown in our issue of Sept. 3, and this has brought us some communications on this subject of paving street railway tracks. Mr. H. L. Weber, City Engineer of Richmond, Ind., has sent drawings showing the track construction and special brick or block for T-rail track, as used in that city. The special brick are of different lengths, consequently all joints are broken. On the outside of the rails Portland cement mortar is filled in under the head, so that the paving next to the rail has a full bearing, the same as at the curb. The special blocks form a groove along the rail and if the track work is properly done this is considered as desirable as the grooved head. The street surface is as continuous as it is possible to make it with a railway track upon it. The track drains are placed at intervals of 400 ft. and at points of break of grade.



Section of Grooved Block

Cross Section of Track.

Brick Paving For Street Railway Tracks; Richmond, Ind

Mr. H. P. Jones, of Steelton, Pa., writes as follows, in regard to the article in our issue of Sept. 3:

> The suggestion of the molded brick is excellent, but would be a useless expense to incorporate in the Cortland plan, where every rail chair is in practice a water conductor to the reservoir which in six months' time will be formed under the concrete at the ties, and finally extending under the entire track system. It does not require a scientifically-trained mind to forecast the result when this reservoir becomes frozen solid.
>
> The first intimation to be had that the foundation will give way, will be that the bricks next the gage side of the rails will have a tendency to stand on end; the patrons of the railway will be treated to a very unpleasant sensation while riding, and the stockholders will be wondering why the management is continually purchasing new wheels. The chief advantage of a concrete base for a pavement, over any other kind, is its stability, making maintenance and renewals a minimum cost. When that end is not attained, the money has been thrown away. I do not believe the Cortland plan is based on engineering principles.

◆

ELECTRIC LOCOMOTIVE ON THE MANHATTAN ELEVATED RAILWAY.

As stated in our issue of Oct. 8, a trial of electricity is being made on the 34th St. branch of the Manhattan Elevated Ry., in New York city. The line is only a few blocks in length, extending from the Third Ave. line to the Long Island Ferry.

The motor car was designed by Mr. J. B. Entz, representing the Storage Battery Co., of Philadelphia. The trucks are from a dummy engine, the drivers being 28 ins. diameter. The body of the car is 18 ft. long, and 8 ft. high, in the center, where the motorman's cab is placed. From the cab the roof slopes in either direction to a height of 3 ft. at the ends. The weight is ten tons. A 400-volt current is supplied from a third rail, of T section, placed on the outside of and at an elevation of about 10 ins. above the track rails. Contact is made by two cast-iron sliding shoes, hanging loosely from the front and rear axle bearings of the trucks. The idea of the two shoes, as explained by Mr. Entz, being to fortify against breaks in the contact, which might occur by the jumping of a single shoe.

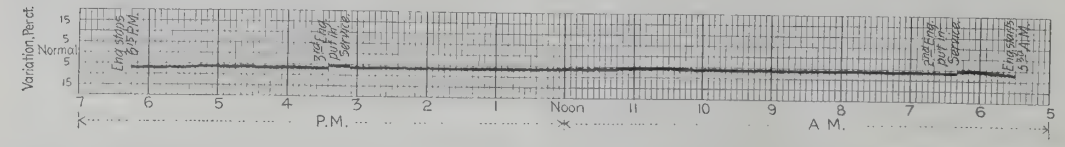
The electrical equipment includes two General Electric motors, each of 125 HP., and storage batteries of 256 cells, weighing 80 lbs. each. These cells are constantly in parallel with the power-house circuit and are intended to equalize the load. When no power is needed, as on a down grade, the current is consumed in charging the batteries; when the load is heavy, the extra current required is supplied from the storage batteries. This has the effect of making the dynamo load more uniform, or of maintaining a constant load on the generators, independent of the variable current required by the locomotive. This permits the use of smaller machines at the central station, and a consequent saving of coal. The location of the batteries in the power-house would in the same way equalize the central station load, but the fluctuations would still be felt in the distributing conductors. By placing the storage battery on the locomotive at the exact point where the sudden fall of potential occurs at the time of heavy demand for power a steady current is maintained in the line conductors; a sudden demand, as in starting, for a large amount of current is supplied by the battery and no additional demand is made upon the current conductor; both pressure and current remaining constant. In the old system of distribution both machines and conductors must be made large enough for the maximum demand; and the drop in voltage, which occurs at a distance from the power-house, causes the motors to work inefficiently just when the demand for power is greatest. By this method the feeders and conductors can be designed to carry the average load. The conductor at a long distance from the power-house could also be made smaller, the small current in the line being reinforced automatically by the battery.

This system also allows the third rail to be discontinued at crossovers, the load at such places being imposed upon the batteries. The batteries alone will supply sufficient power to operate a train for 15 to 20 miles at a speed of 25 miles per hour.

The first cost of the electric locomotive is said to be slightly above that of the steam locomotives now in use.

AN EXAMPLE OF GOOD SPEED REGULATION BY A LARGE ENGINE.

We reproduce herewith, on a reduced scale, a diagram made by the Moscrop speed recorder of a 13 hours' run of the No. 4 engine at the power house of the People's Traction Co., Beach and Green Sts., Philadelphia. The engine is a twin tandem compound, direct coupled, built by the Edward P. Allis Co., of Milwaukee, Wis. The cylinders are 24 and 48 ins. diameter and 60 ins. stroke. The normal speed is 65 revolutions per minute. On the diagram the distance between any two of the horizontal lines is equivalent to a variation of 5% in the speed of the engine. The autographic record shows a practically perfect regulation, the line drawn by the pencil being almost exactly parallel to the horizontal lines of the diagram. There are no noticeable deviations at any point except where additional engines were started or stopped.



SPEED DIAGRAM FROM AN ALLIS 24 × 48 × 60 IN. ENGINE AT THE POWER HOUSE OF THE PHILADELPHIA TRACTION CO., JUNE 1, 1896.

NOTES FROM THE ENGINEERING SCHOOLS.

Columbia University, New York City, entered upon its 143d academic year on Oct. 5. This will probably be the last year that it will occupy the present buildings, as it is likely that in another year the new buildings on the new site on Riverside Drive will be ready for occupancy. Increases in all departments of the University are reported. Mr. Chas. C. Worthington, M. Am. Soc. C. E., has offered to equip a laboratory of hydraulic engineering in the new School of Mechanical Engineering. The gift is to be made in the name of his father, the late Henry R. Worthington. The following additions have been made to the faculty: Adolph Black, tutor in civil engineering; Chas. Durleth, assistant in civil engineering; Heinrich Ries, assistant in mineralogy. A notable change has been made in regard to the old School of Mines, which will hereafter no longer be known by its old name, but by the name of the School of Applied Science, while the School of Chemistry, the School of Architecture, and the School of Engineering will be set apart as distinct schools, all four schools being under the charge of one faculty, known as the faculty of Applied Science. In his address at the opening of the new year President Low declared that the move toward establishing a school of mechanical engineering was a most important one, since the city of New York was the greatest manufacturing center in the country. He said: "I think it may be said that the removal of the University may take place next year as has been proposed. To facilitate our removal we greatly need at once the gift of a building for physics, costing $250,000; a building for engineering, costing $250,000; a gymnasium, costing, with apparatus, $375,000."

The Missouri Military Academy, at Mexico, Mo., was burned to the ground early in the morning of Sept. 24, while 80 cadets were asleep in the building. About twenty of these were more or less severely injured in jumping from the windows. The loss is estimated at $70,000, of which $40,000 is covered by insurance. The Academy was opened in 1890, and the building was one of the most complete in the State. There is a suspicion that the fire was the work of an incendiary.

The Oregon Agricultural College, at Corvallis, Ore., began its year's work on Sept. 17, under the management of a new president, Mr. H. B. Miller, of Grant's Pass, Ore., who succeeded Mr. John M. Bloss, resigned. Prof. F. Birchtold, of the Department of Physics and History, has been appointed Dean of the College, a newly created office. An "Insectory" has been built for the Entomological and Botanical departments, to aid in the study of the habits and life of injurious insects and fungous diseases. The Experiment Station, so far as possible will bend all its energies along one line at a time, all the departments taking up their phase of the same subject. This year "the Prune," Oregon's great industry, will be given special attention. The mechanical course has one young lady taking all the work of the course, and doing work equal to that of any of the young men.

The University of Wisconsin, Madison, Wis., has a College of Mechanics and Engineering, which offers three separate systematic courses, viz.: civil, mechanical and electrical engineering. Special encouragement is given to those students who can afford the time to graduate in a collegiate course before entering the course of engineering. By electing the mathematics required of engineers during the collegiate course the degree in engineering can be obtained in two additional years. Greater satisfaction and profit is gained from the study of engineering when the student has already acquired a broad and thorough general training. The staff of instruction in the engineering college, including professors, assistants and special lecturers, numbers over forty. Dr. Chas. Kendall Adams, LL. D., is president of the University.

The Newark, N. J., Technical School, which has been in successful operation for some years, will not open until some time in November, owing to delay in the construction of its new building. The school year will be extended later in the spring of 1897, to make up for the loss of time at the beginning. Prof. Chas. A. Colton, E. M., is director. Mr. Maurice A. Miller, instructor in mechanical drawing and mechanical engraving for the last few years will also give instruction in descriptive geometry, taking the place of Mr. A. W. Jacobi, resigned.

The Department of Engineering of the University of Michigan, Ann Arbor, Mich., has issued an annual Announcement and Register of Alumni for 1896-7. The Register contains a list of Alumni, dating back to 1860.

The University of Nebraska, Lincoln, Neb., issues a brief Announcement of its School of Mechanic Arts, with photographic illustrations of the exterior and interior of its mechanical and electrical laboratory. Primarily the school is intended for those young men who expect to enter some one of the mechanical trades, although it is hoped that the stimulus given by this school will, in many cases, be such that a collegiate course in one of the engineering groups will be pursued. Tuition in the school is free, and other expenses are remarkably low. Prof. C. R. Richards is the director of the school.

Brown University, Providence, R. I.—The annual report of the President, together with the reports of professors in charge of the departments, have been published in a pamphlet of 80 pages. From the President's report we learn that increased expenditures for needed improvements and apparatus caused a financial deficit in the past year, to make up for which it has been necessary to reduce salaries and to discontinue the services of four professors in the departments of Germanic Languages and Literature, Biology, Philology, and Architecture. There are 35 students in the University pursuing courses in mechanical engineering and 38 in civil engineering. Mr. Edward C. Burnham, B. S., formerly instructor in mechanical drawing and engineering, has been made Associate Professor of Mechanical Engineering.

The Michigan State Agricultural College boasts of being the oldest agricultural college in the country, having been established in 1857, or five years before the passage of the Morrill Land Grant Act, by the U. S. Congress, which brought about the establishment of most of the agricultural colleges. The college is steadily increasing in prosperity and in influence. Five years ago a mechanical engineering department was established, which is under the direction of Prof. Chas. L. Weil, with Prof. P. M. Chamberlain as assistant in charge of shops. It is equipped with foundry, machine pattern and forge shops. The college receives a good income from the investment, the proceeds of its land grant; and an annual appropriation from the state.

From Rensselaer Polytechnic Institute we learn that Prof. James McGiffert, Jr., C. E., Assistant in Mathematics, has obtained leave of absence for one year in order to study pure mathematics at Harvard University, and to obtain the degree of Ph. D. His place has been filled by William E. Whitney, C. E. Benedict Papot, professor of French, has resigned, and Arthur de Pierpont has been appointed in his place.

At the New Hampshire College of Agriculture and the Mechanic Arts, Durham, N. H., recent new appointments to the faculty are: Joseph H. Hawes, instructor in free-hand drawing; George H. Furbish, foreman of woodwork; Clement S. Morris, actuary and purchasing agent.

At the Polytechnic Institute, Brooklyn, N. Y., the Institute course in civil engineering, the graduates from which have received the degree of B. S., has been extended by a year of post graduate work, and those completing the course will receive the degree of C. E. This work will be under the direction of Profs. Plympton and Kimball, assisted by Richard L. Russell, B. S., who, since his graduation, has been employed in the city Board of Public Works. The graduates of the civil engineering course have so far taken the positions in every civil service examination held in Brooklyn, over all competitors.

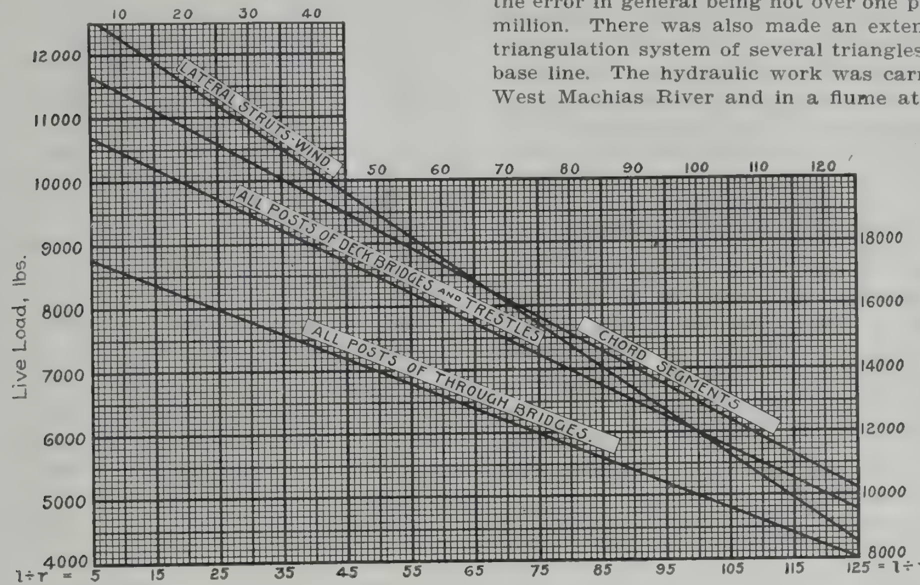
The Florida State Agricultural College, Lake City, Fla., is prospering under the management of its president, Oscar Clute, who was formerly president of the Michigan Agricultural College. The department of mechanics, while not having as complete an equipment as many of the Northern schools, is yet doing good and efficient work, both in theory and practice. During the vacation two of the graduates have set up without any outside help a complete electric plant, with a 100-HP. engine and two 1,000-light dynamos. Mr. N. H. Cox, one of the graduates of the school, has been elected assistant in mechanics. Prof. H. C. Powers is in charge of the mechanical department.

At the Michigan Mining School, Houghton, Mich., the following appointments have been made for the year 1896-7; Louis M. Hardenburgh, A. B., E. M., instructor in chemistry; Albert J. Houle, E. M., instructor in civil and mining engineering; Mr. George Wass, instructor in pattern shop; and Mr. Nathan S. Osborne, assistant in the physical laboratory. The school opens this fall with a large attendance. In September, 1895, the change from the rigid course to the elective system was made after much deliberation, and good results have followed. The entering class this year is larger than at any time since the organization of the school, ten years ago. The standard of work required has not been lowered, but the student is allowed freedom of choice to take the work best suited to his needs. An interesting paper on the "Elective System in Engineering Colleges," was read before the last meeting of the Society for the Promotion of Engineering Education, by M. E. Wadsworth, Ph. D., Director of the School, who perfected the system as used in the mining school.

At the Massachusetts Institute of Technology, the following is the provisional list of appointments for 1896-7; Associate Prof. C. Frank Allen has been appointed Professor of Railroad Engineering; Associate Prof. A. E. Burton, Professor of Topographical Engineering; Associate Prof. Dwight Porter, Professor of Hydraulic Engineering; Associate Prof. Peter Schwamb, Professor of Mechanism and Director of the Workshops; Assistant Prof. Linus Faunce, Associate Professor of Drawing; Mr. W. H. Lawrence, Assistant Professor of Architecture; Mr. A. G. Robbins, Assistant Professor of Highway Engineering; Dr. J. J. Skinner, Assistant Professor of Mathematics; Mr. G. H. Barton, Assistant Professor of Geology.

The school year opened on the 30th of September, and the preliminary registration shows a slight increase over the registration at the same period in 1895. Should the final registration bear the same relation to the preliminary this year as it did last year, the number of students will slightly exceed 1,200.

The increase in the number of students taking the course in Organic Chemistry has rendered imperative an increase in the floor space devoted to this laboratory. The necessary accommodations have been obtained by the removal of the chemical library from the fourth to the third floor of the Walker Building, and the conversion of this room into laboratories.



UNIT STRESSES ALLOWED IN COMPRESSION MEMBERS OF MEDIUM STEEL BY COOPER'S 1896 SPECIFICATIONS FOR HIGHWAY BRIDGES.

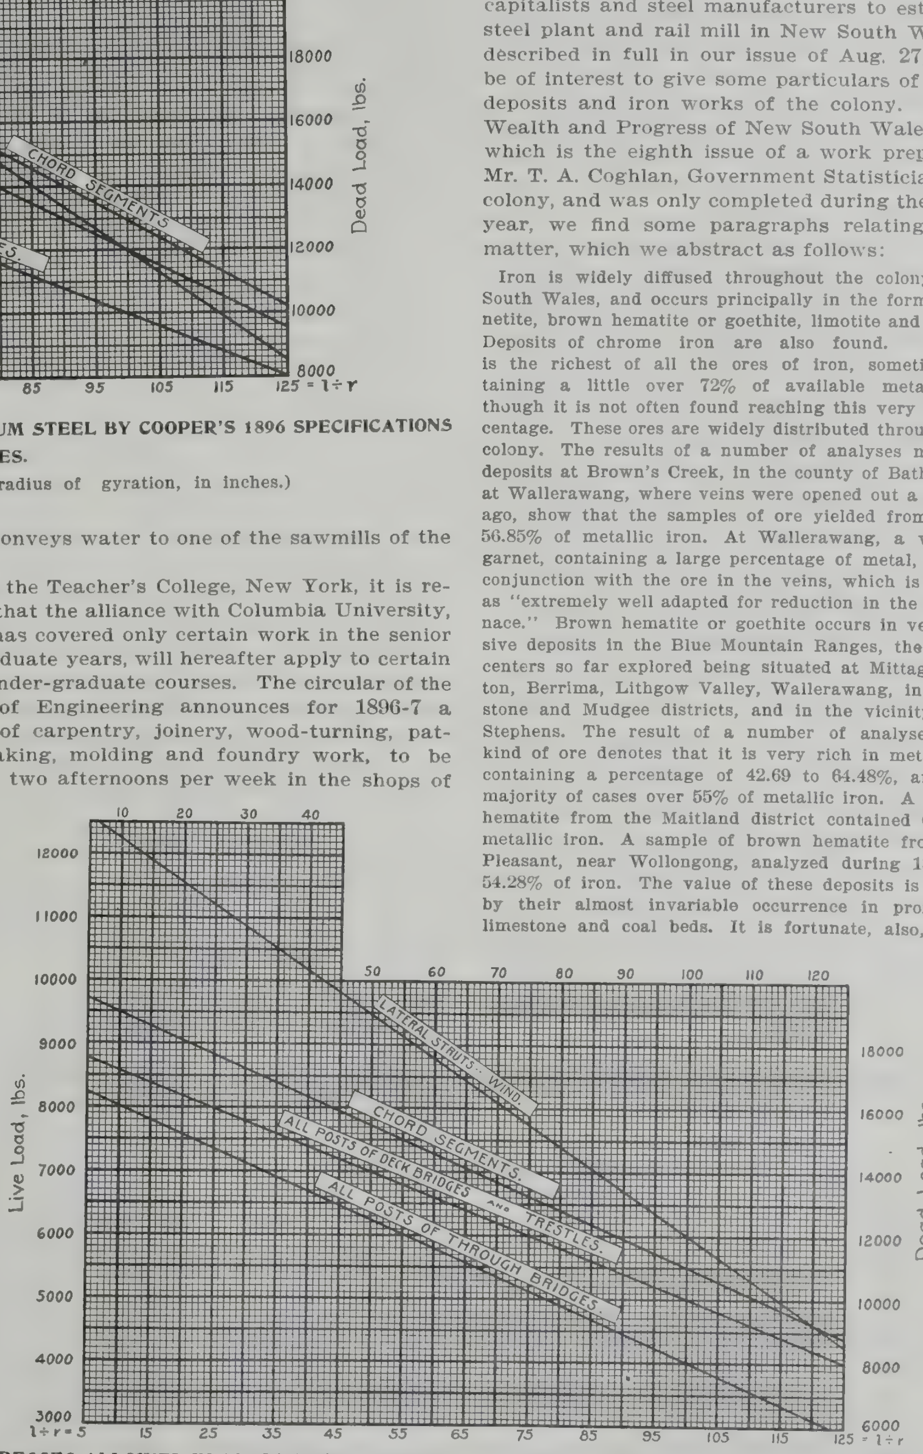
(l = length of member, in inches; r = least radius of gyration, in inches.)

The Department of Architecture has recently secured an important addition to its collection of lantern slides. During the stay of the summer school, in London and Paris, Professer Homer selected 2,600 views of buildings and cities in Europe, Russia and the East. These views will supplement the present collection of the department, and will materially assist the illustration of the lectures given by its instructors. The views of Spanish, Russian, Indian and Chinese architecture are particularly valuable as they include a large amount of material at present not available in any other form.

The season of 1896-7 of the Society of Arts, opened on Oct. 8, with a meeting in the Rogers' Building. Prof. Sedgwick called attention to certain serious practical difficulties which beset the problem of supplying large communities with wholesome milk. The recent occurrence of numerous epidemics of typhoid fever in Massachusetts and elsewhere, which have been traced directly to infected milk, has led Prof. Sedgwick, who has personally investigated several of these epidemics, to propose a reconsideration of the whole question of milk supply of cities, with reference to the sources of danger and the means of removing them. At the same meeting a notable development of the biological work of the Institute on the technicological side was brought to the attention of the society. Mr. S. C. Prescott, Instructor in Biology, and Mr. Lyman Underwood, have, for some months, been closely engaged in a study of the causes of spoiling of canned clams and lobsters. This evil has become so common as to command the earnest attention of the trade. Not only is the outright loss considerable; but the offence given by the spoiled goods is of a kind seriously to affect the market. Messrs, Prescott and Underwood, in the course of their investigation, have found that under certain conditions imperfect sterilization occurs in the ordinary processes of canning clams and lobsters, resulting occasionally in the blackening and spoiling of the entire contents. They have identified certain micro-organisms in the spoiled cans, which are peculiarly resistant to the processes of sterilization, requiring the application of exceptional means to overcome the difficulty and to insure the safety of the foods in question.

The Institute's Summer School of Civil Engineering was held at Machias, Me., during the month of June. The members of the institute faculty in charge were Professors Alfred E. Burton, Dwight Porter and A. G. Robbins, and they were aided by Mr. H. K. Barrows, assistant in the department. Fourteen students of the third year made up the rest of the party. The work of the school is of an advanced nature, and only students who have finished the third year are admitted. The work was entirely in the field, and was in three parts, topographical, geodetic and hydraulic. In the geodetic work, a base line over half a mile in length was measured, with extreme accuracy, the error in general being not over one part in one million. There was also made an extension of a triangulation system of several triangles from the base line. The hydraulic work was carried on in West Machias River and in a flume at Machias, which conveys water to one of the sawmills of the town.

From the Teacher's College, New York, it is reported that the alliance with Columbia University, which has covered only certain work in the senior and graduate years, will hereafter apply to certain other under-graduate courses. The circular of the School of Engineering announces for 1896-7 a course of carpentry, joinery, wood-turning, pattern-making, molding and foundry work, to be held on two afternoons per week in the shops of Teachers' College under the instruction of members of Teachers' College staff.



UNIT STRESSES ALLOWED IN COMPRESSION MEMBERS OF MEDIUM STEEL BY COOPER'S 1896 SPECIFICATIONS FOR RAILWAY BRIDGES.

(l = length of member, in inches; r = least radius of gyration, in inches.)

At the University of New York, Mr. Collins P. Bliss, recently assistant engineer in the Globe Iron Works, of Cleveland, has been apointed instructor in the engineering school. Mr. Bliss is a graduate of Princeton in the class of 1888, and of the Columbia School of Mines in 1891. His special work is to be laboratory courses in steam engineering and practical hydraulics.

A GRAPHICAL METHOD OF FINDING ALLOWABLE STRESS IN COMPRESSION MEMBERS.

The accompanying diagrams show the unit stresses in compression members of both highway and railway bridges, allowed by Mr. Theodore Cooper's 1896 Specifications. The diagrams were plotted by Mr. A. Lincoln Hyde, Assoc. M. Am. Soc. C. E., New England Building, Cleveland, O., and we are indebted to his courtesy for the privilege of reproducing them here. The diagrams explain themselves, and will, we believe, be found exceedingly convenient by those engaged in the design of structural work.

* * *

IRON IN NEW SOUTH WALES.

In view of the opportunity offered to American capitalists and steel manufacturers to establish a steel plant and rail mill in New South Wales, as described in full in our issue of Aug. 27, it may be of interest to give some particulars of the iron deposits and iron works of the colony. In "The Wealth and Progress of New South Wales, 1894." which is the eighth issue of a work prepared by Mr. T. A. Coghlan, Government Statistician of the colony, and was only completed during the present year, we find some paragraphs relating to this matter, which we abstract as follows:

> Iron is widely diffused throughout the colony of New South Wales, and occurs principally in the form of magnetite, brown hematite or goethite, limotite and bog-iron. Deposits of chrome iron are also found. Magnetite is the richest of all the ores of iron, sometimes containing a little over 72% of available metallic iron, though it is not often found reaching this very high percentage. These ores are widely distributed throughout the colony. The results of a number of analyses made from deposits at Brown's Creek, in the county of Bathurst, and at Wallerawang, where veins were opened out a few years ago, show that the samples of ore yielded from 40.89 to 56.85% of metallic iron. At Wallerawang, a variety of garnet, containing a large percentage of metal, occurs in conjunction with the ore in the veins, which is described as "extremely well adapted for reduction in the blast furnace." Brown hematite or goethite occurs in very extensive deposits in the Blue Mountain Ranges, the principal centers so far explored being situated at Mittagong, Picton, Berrima, Lithgow Valley, Wallerawang, in the Rylstone and Mudgee districts, and in the vicinity of Port Stephens. The result of a number of analyses of this kind of ore denotes that it is very rich in metallic iron, containing a percentage of 42.69 to 64.48%, and in the majority of cases over 55% of metallic iron. A sample of hematite from the Maitland district contained 60.83% of metallic iron. A sample of brown hematite from Mount Pleasant, near Wollongong, analyzed during 1891, gave 54.28% of iron. The value of these deposits is enhanced by their almost invariable occurrence in proximity to limestone and coal beds. It is fortunate, also, that the main lines of railway pass through the region where the deposits are most easily worked.
>
> Limonite (a variety of brown hematite) principally occurs at Lithgow, Eskbank and Bowenfels, in the Blue Mountains; in several parts of the Hunter River coal field; and at Bulli, in the Illawarra District. This ore is usually found very rich in metal, and contains an average of over 50% of iron; while the English clay bands, which are mostly carbonates, only contain about 30% of metallic substance. It occurs in lenticular layers of no great extent, in the coal measures. Bog-iron ore, which is impure

limonite, is principally found at Mittagong, and assays of this ore gave a percentage of metal equal to an average of over 45%.

No other colony of Australia possesses deposits of iron ore approaching in extent or richness those of New South Wales; it is, therefore, probable that at some future time this colony will become the great seat of the iron industry of Australia. As illustrating the present extent of the supply required, the value of all descriptions of iron, machinery and iron manufactures imported into New South Wales in 1894 was $5,946,245. The average yearly import for the four years 1890-1893 amounts to $13,134,755 for New South Wales, and $32,507,230 for Australasia; and the quantity of pig-iron required to produce the material represented by these values is approximately 190,000 tons and 480,000 tons per annum for New South Wales and the whole group of colonies respectively.

In a report, dated January, 1891, by the late Mr. C. S. Wilkinson, Government Geologist, it is stated that the iron deposits in the districts of Mittagong, Wallerawang and Rylstone contained in sight 12,944,000 tons of ore, estimated to yield 5,853,000 tons of metallic iron. These districts are most favorably situated for the establishment of smelting works. Some years ago public attention in England was drawn to the possibility of manufacturing iron within the colony and a mining expert was sent out from that colony to inspect the iron, lime and coal deposits and to report upon the probable cost of establishing the industry in the colony; but so far the visit has been without result.

The principal works for the manufacture of iron from the ore are situated at Eskbanks, near Lithgow, where red siliceous ore, averaging 22%, and brown hematite, yielding 50% metallic iron, have been successfully treated. Abundance of coal and limestone are found in the neighborhood. The establishment, however, has for some time abandoned the manufacture of pig-iron for which it was originally built. The work now carried on consists of the re-rolling of old rails, and the manufacture of iron bars, rods and nails and of ordinary castings. The quantity manufactured from scrap during 1894 was 2,368 tons, valued at $85,850. A successful attempt has been made at Mittagong to make gas pipes, etc., from iron smelted from the ore, and taken direct to the mold, without first making it into pig-iron. Some years ago the iron smelting works at Fitzroy, Mittagong, were established, but after producing a considerable quantity of pig-iron the operations were discontinued. Some samples of ore, coal and limestone obtained in this district, with pig-iron and castings manufactured therefrom, were exhibited at the late mining exhibition at London, and obtained a first award. In the Broken Hill district, 254 tons of iron ore, valued at $1,280, were raised during 1894, chiefly for the purpose of flux.

Deposits of manganese ore have been discovered in various parts of New South Wales. Pyrolusite, in the form of black oxide and manganese, dioxide, occurs principally in the Bathurst districts and at Bendemeer. Wide veins have also been found in the Glen Innes district, near the Newton-Boyd road. Some of the specimens analyzed have yielded a very high percentage of metal; but the demand for manganese in the colony is very trifling, and until a foreign market is found, or local manufactories requiring the metal spring up, the rich deposits of this ore will remain comparatively untouched. The ore is found extensively in conjunction with iron in coal and limestone country, and often contains a small percentage of cobalt.

DIRECT CONNECTED ENGINES FOR ELECTRIC POWER STATIONS IN GERMANY.

(With inset.)

Our inset this week illustrates three steam engines, recently installed in electric power stations in Germany, which will be interesting to American engineers in showing that the trend of practice in Germany is like that in America, toward vertical compound or triple expansion engines of short stroke, connected directly to the dynamos, while the German construction is notable for greater complexity of details and variety of forms of valves as compared with the usual simplicity of American designs. The American engine-builder is usually compelled by the high price of skilled labor and by intense competition to build an engine which has the smallest possible number of parts, and to so design these parts that they can be made in quantities by machinery with a minimum expenditure of labor. The German builder seems to be subject to no such restrictions and is able to give freer scope to his ideas in designing. The result he obtains is apt to be, as shown in these illustrations, an engine which is admirable as a piece of workmanship, fairly durable and highly economical, but one which is not apt to be copied by American builders, on account of the restrictions to which they are subjected. Among the features especially noticeable in these German engines are massiveness of frames, large extent of bearing surfaces, and comparatively low speed, the highest piston speed figured from the data given below being 512 ft. per minute. In all three engines the expansion or cut-off valve of the high pressure cylinder is separated from the main valve, and is driven by a separate eccentric, and in the two larger engines separate expansion valves are also provided for the intermediate cylinders. In the triple-expansion engine two separate admission slide valves are provided, each with means for varying the travel by hand. This would be quite unusual in an American engine as small as 700 HP. The following description of these engines, from the "Zeitschrift des Vereines Deutscher Ingenieure," has been translated by Mr. O. J. Marstrand, Assoc. M. Am. Soc. C. E.

The first engine described in the following paragraphs is installed at the electric station of New-Bydzow, Bohemia, and forms part of a plant designed for a total output of 160 kilowatts, but capable of future extension. At the present time, however, there are two of these vertical compound condensing engines of 90 HP. each, with dynamos coupled directly to the main shaft. The diameter of the high pressure cylinder is 300 mm. (11.8 ins.); that of the low pressure 470 mm. (18.5 ins.), and their stroke 350 mm. (13.8 ins.) at 220 revolutions per minute.

The high pressure cylinder is controlled by two piston valves, the main valve being made in two parts, connected by an iron pipe. It is provided with double inlet passages, and fits closely, without any packing in the bushing, which latter is held in place by three set screws. Its weight is balanced in the usual manner, by increasing the diameter of the upper part. The expansion or cut-off valve, which is made in one piece, and weighs only 5 kilos. (11 lbs.) is also fitted into the main valve without any packing. The length of these valves is reduced as much as possible. The expansion valve is operated directly, while the main valve is operated by means of an intermediate rod, which may be readily removed. The hub of the fly-wheel forms the eccentric for working both valves. The weight of the expansion valve, rods and eccentric ring, and the reduced weight of the turning eccentric are balanced by a vertical plunger, moving in the top of the steam chest. The maximum reaction on the governor becomes 2½ times as great for unbalanced as for balanced weights.

The low pressure cylinder is controlled by only one valve, which is made in two parts as above. It has a Trick passage* and is provided with packing rings on both exhaust sides.

The air pump is driven by cast-iron rods and levers, connected to the cross-head pin of the low pressure cylinder, and works noiselessly in spite of the rather high number of revolutions. The necessary steam is provided by three fire-tube boilers with 110 sq. m. (1,184 sq. ft.) heating surface, one or two of these being in use at a time, as required.

The second and third engines illustrated have lately been placed in an extension of the electric light and power station at Munich. The original station was used for the purpose of street lighting only; it was, however, recently decided to increase its capacity, and to use the increased power for the operation of a street railway. The main dimensions of the smaller engines are: Diameter of high-pressure cylinder, 510 mm. (20 ins.); diameter of low pressure cylinder, 760 mm. (30 ins.); stroke, 480 mm. (18.9 ins.) with 150 revolutions per minute. They are vertical compound engines, having the dynamo coupled directly to the main shaft. The main valve of the high-pressure cylinder is a balanced slide valve, while the expansion valve is cylindrical; the low pressure cylinder has a balanced slide valve. The engines work at an initial pressure of 9 atmospheres (132 lbs. per sq. in.), and are condensing; they can, however at any time, be changed to exhaust into the atmosphere. The normal rating is 250 HP., maximum 350 HP. Under normal loading and a steam pressure of 9 atmospheres, a consumption of 7.25 kilos. (16 lbs.) steam per HP. hour with condensation, and 12 kilos. (26.5 lbs.) without condensation is guaranteed. The diameter of the fly-wheel is 2.8 m. (10 ft. 2 ins.) and it weighs about 6,900 kilos. (15,200 lbs.). The Hartung spring governor acting upon the expansion valve, controls the speed with a maximum variation of 1% for a change of load of 25%. The coefficient of fluctuation during a uniform loading is 1-250.

The third engine is also directly coupled to its dynamo, and is a vertical triple-expansion engine, controlled by a Hartung spring governor; the piston valve of the intermediate cylinder has a Meyer cut-off, with hand adjustment, and the low pressure cylinder has two balanced slide valves, as shown in the plan, also adjustable by hand. The engines are operated at a pressure of 12 atmospheres (176 lbs. per sq. in.), and can be run as condensing or non-condensing. Their principal dimensions are: Diameter of high-pressure cylinder, 490 mm. (19.3 ins.); diameter of mean-pressure cylinder, 800 mm. (31.5 ins.); diameter of low-pressure cylinder, 1,180 mm. (46.5 ins.); stroke, 600 mm. (23.6 in.), with 120 revolutions per minute. The normal rating is 500 HP., maximum 700 HP. The steam consumption per HP. hour is guaranteed at 6.5 kilos. (14.3 lbs.) and 10 kilos. (22 lbs.), with or without condensation, respectively. The diameter of the fly-wheel is 3.5 m. (11 ft.), and it weighs 8,600 kilos. (18,900 lbs.).

Special attention was paid in the Munich engines, which were designed by Engineer Hammel, to making all the principal parts easily accessible. Their massive construction will be particularly noticed, as also the fact of the bed plates being made in one piece, and of such a depth as not to require the stone foundation to rise above the floor level. The cross-head slides on the smaller engines are made plane surfaces to allow for the expansion of the two cylinders on a single base-plate. In the larger engines the three cylinders are independent of each other, and have cylindrical cross-head slides.

The injector condensers are placed below the engines; as are also the air pumps, of which there is one to each of the compound engines, and two for the triple expansion engines; they are operated by levers, extending from the cross-heads.

Three steam boilers provide the necessary steam; the heating surface of each boiler is 180 sq. m. (19,400 sq. ft.), its grate surface 3.7 sq. m. (40 sq. ft.).

The piping is all in duplicate; the diameter of the pipes at the boilers, and as long as they run separately, is 150 mm. (5.9 in.), while they join into pipes of 250 mm. (9.8 in.) diameter. Provision is made for expansion and contraction at the joints and elbows. The boilers are supplied with about 187,000 lbs. of water per hour. The feed pipes, and the steam pipes for the feed pumps, are built in a circuit, so as to make it possible to feed either boiler by either pump.

LEGAL DECISIONS OF INTEREST TO ENGINEERS.

The Use of Sand on Track.

It is for the jury to say whether it was negligence not to have had sand on an electric car for stopping in emergencies, though it was a season when the rails were dry and dusty, where the evidence showed that the streets had been sprinkled shortly before the accident, and that the rails were slippery with thin mud; that in such cases the wheels of the car will slide, making it very difficult to stop; and that if there had been sand on the car it could have been stopped more easily than it was.—Penny v. Rochester Ry. Co. (Sup. Ct. App. Div.), 40 N. Y. Supp. Rep., 172.

Contributory Negligence of Passenger.

The Supreme Court of Minnesota holds that where a party falls and is injured by reason of getting off the car while it is slowing down for the purpose of stopping, he cannot recover, as he is guilty of contributory negligence.—Defoe v. St. Paul City Ry. Co., 68 Northwestern Reporter, 35.

Running a Dummy Engine Backward.

The running of a dummy engine, says the Supreme Court of Alabama, backward at a greater degree of speed than that prescribed by the city ordinance is a violation of same, though the speed was within the limitation for running forward, and it was safer to run backward than forward. —Highland Ave. & B. R. Co. v. Sampson, 20 Southern Reporter, 566.

---

*A passage through the body of the valve which provides a double inlet for the steam, making what is commonly known as the Allen valve in America, and as the Trick valve in Europe.

Negligence of Sub-Contractor.

Where a street car company, authorized by charter to build a car line, lets a contract for construction to an independent contractor, without any agreement as to the particular manner in which the work shall be done, it is not liable for injuries caused by a wire stretched across the road by such contractor in the course of the work.—Sanford v. Pawtucket St. Ry. Co. (Sup. Ct. R. I.), 35 Atlantic Rep. 67.

Power of Railways to Adjust their Rates.

Subject to the two leading prohibitions, that their charges shall not be unjust or unreasonable, and that they shall not unjustly discriminate so as to give undue preference or disadvantage, the laws of the United States leaves common carriers, as they were at common law, free to make special contracts looking to the increase of their business, to classify their traffic, to adjust and apportion their rates so as to meet the necessities of commerce, and, generally, to manage their important interests upon the same principles as are regarded sound and adopted in other trades and pursuits.—Interstate Commerce Commission v. Ala. Midland Ry. Co. (U. S. Cir. Ct. App.), 74 Federal Reporter, 715.

Mining: Rule of Safe Place.

The United States Circuit Court of Appeals recently said: It is a positive duty which the owner of a mine owes to his employees, after the mine is opened and timbered, to use reasonable care and diligence to see that the timbers are properly set, and to keep them in proper condition and repair, and for this purpose to provide a competent mine boss or foreman, to make timely inspection of the timbers, walls, and roof of the mine. —Western Coal & Mining Co. v. Ingraham, 70 Fed. Rep., 219.

CIVIL SERVICE EXAMINATIONS for engineering positions will be held shortly in New York and Washington. On Thursday, Oct. 22, the New York City Civil Service Commission will hold an examination for Building Inspectors, who must be either "architects, civil engineers, masons, carpenters or iron workers who shall have served at least ten years as such." On Friday, Oct. 23, an examination will be held for Inspectors of Iron and Steel, who are required to have had ten years' experience. Applications for these examinations may be procured from S. William Briscoe, Secretary of the Civil Service Commission, New Criminal Court Building, New York city. On Oct. 28, 29, 30 and 31 the U. S. Civil Service Commission, Washington, D. C., will hold examinations for positions in the office of the Supervising Architect, Treasury Department, as follows: Senior architectural draftsman (6 years' experience required, salary $1,600 to $2,000 per year); architectural draftsman (4 years, $1,200 to $1,400); junior architectural draftsman (no experience, $600 to $1,000); structural iron draftsman (2 years, $1,600); heating and ventilating draftsman (2 years, $1,200); computer (no experience, $1,200 to $1,800). Applicants must file with their applications certificates or letters from present or former employers to show that they have had the required practical office experience with some reputable firm of architects or engineers.

◆

THE EIGHT-HOUR LAW lately brought about an absurd suit in Providence, R. I., in connection with the government work on the new mortar battery at Fort Adams. The contractor for that work was sued by the Newport Trades Council for working men nine hours a day, and thus violating the United States Statute prohibiting government contractors from working their men more than eight hours per day. In the trial before U. S. Commissioner Blodgett, the charge was admitted in the case of the men named; but it was shown that it was an emergency case caused by springs breaking out in the foundation excavation. It was also pointed out that the statute provided that the law was not to apply in such cases, and the complaint was dismissed upon the ground that there was no proof of wilful intent to disregard the law, and because the time clause in the contract required extraordinary activity on the part of the contractor.

◆

A METEOROGRAPHIC KITE was sent to an altitude of 9,385 ft. above sea level, at the Blue Hill Observatory on Oct. 8, thus breaking all previous kite altitude records. This "kite" was made up of seven Eddy and two Hargrave kites, from 6 to 9 ft. in diameter, exerting a pull of from 50 to 95 lbs. upon the piano-wire employed. More than three miles of wire were paid out. The kites carried a meteorograph making its record in ink. This record showed a temperature of 46° F. at the ground and 20° F. at an altitude of 8,750 ft. The kites remained at an altitude of over one mile for three hours.

◆

THE PEARY ARCTIC EXPEDITION has returned to North Sydney, N. B., from its summer trip. The party was made up of representatives from Cornell University, the U. S. Coast Survey and the Massachusetts Institute of Technology. They bring back valuable botanical and other collections, and the U. S. Coast Survey party made a series of pendulum and magnetic observations. Lieut. Peary, who returns with the party, writes to the New York "Sun" that the result of the Nansen and Jackson expeditions proves that Greenland is the only land base for an expedition to the North Pole, and he outlines a proposed line of advance towards that point. He says that Lockwood and himself sighted the most northerly land known, extending certainly to 84° or 85° North. Lieut. Peary proposes to organize another Arctic expedition next season, associating with him the leading American geological and archaeological societies. In his absence the interior tableland of Greenland, traversed by him, has been named Peary's Land, by the American and European geographical societies.

◆

A NEW ARMOR STEEL has been invented by Samuel Maxim, a brother of Hiram Maxim, of machine-gun fame. Mr. Maxim, according to the Philadelphia "Record," claims to have simplified the process of manufacturing the famed Wootz steel of India, still made by laborious crucible methods in that country. He submits specimens which are said to cut glass with ease and says he can, by his process, much increase the resistance of armor plate while greatly reducing the thickness and weight.

◆

THE WALRAND-LEGENISEL STEEL PROCESS is meeting with considerable success in Europe, according to a paper read by Mr. George J. Snelus at the recent meeting of the Iron and Steel Institute of Great Britain. It has been adopted by two firms in France, two in Germany, two in St. Petersburg, Russia, one in Spain and one in Glasgow, Scotland, one in Erith, England (Fraser & Chalmers) and one in the United States (Potter & Hollis, Chicago). The size of the converters range from 350 kilos to 1 ton. The principal field for the process is for steel castings, which are made solid and very true to pattern, the melted metal being unusually fluid. It is also applicable to the manufacture of special steels which are required in smaller quantities than can be conveniently produced in the ordinary converter or in the open-hearth. A description of the process was given in our issue of March 19, 1896. It differs from the ordinary Bessemer process in the addition of ferro-silicon to the metal in the converter at approximately the time of flame-drop, and making an after-blow. The rapid combustion of the silicon raises the temperature most notably, and finishes the process by burning silicon to a solid (slag) instead of carbon to a gas.

◆

THE SELECTION OF THE SAVAGE RIFLE by the New York state commission appointed to test guns presented by different manufacturers and to report which one was the best for the use of the state militia, has led to a protest by the Winchester Arms Co., of New Haven, Conn., one of the rivals of the Savage Gun Co. A hearing of the protest and of the reply was held by Governor Morton on Oct. 7, and his decision in the matter is reserved. Statements have been made in the daily papers that collusion between the Savage Gun Co. and some members of the commission was charged, but in the argument before the Governor by Gen. Tracy, representing the Winchester Arms Co., he expressly disclaimed any such charge, and claimed only that the commission was not composed of either trained army officers or gun experts, and that the commissioners were not competent judges of firearms.

◆

A HEAVY EXPRESS ENGINE of the Columbia type has been built by the Baldwin Locomotive Works, of Philadelphia, Pa., for the "Black Diamond" express of the Lehigh Valley R. R., the engine having been designed by Mr. S. Higgins, Superintendent of Motive Power of that road. The engine has four driving wheels (the rear pair being the main drivers), a four-wheel leading truck and a pair of trailing wheels. It has the Wootten firebox, cast-steel driving wheel centers, steel engine and tender wheels, rods of I-section, metallic packing, and all the latest improvements in boiler fittings, etc. The boiler jacket is of steel, painted black. The general dimensions are as follows:

Driving wheels (4)	6 ft. 4 ins.
Truck wheels (4)	3 " 0 "
Trailing wheels (2)	4 " 6 "
Tender wheels (8)	3 " 0 "
Driving axle journals	8½ × 11 ins.
Wheelbase, driving	13 ft. 0 ins.
Wheelbase, total	24 " 0 "
Weight on driving wheels	81,800 lbs.
" on truck	29,100 "
" on trailing wheels	30,050 "
" total of engine	140,950 "
" tender	85,000 "
Cylinders	19 × 26 ins.
Steam ports	1⅜ × 19 "
Exhaust ports	3¼ × 19 "
Valves (Richardson balanced), travel	5¾ "
Boiler, diameter of barrel (outside)	5 ft. 1 in.
Boiler pressure	180 lbs.
Tubes (steel), 265, diameter	2 ins.
" length	15 ft. 0 "
Firebox (radial stay), length	9 " 6 "
" width	6 " 8 "
" depth, front and back	3 ft. 10¼ "
Grate area	63.97 sq. ft.
Heating surface, tubes	2,081.24 " "
" " firebox	148.98 " "
" " total	2,230.22 " "
Smokestack (taper), height of top from rail	14 ft. 10 ins.
Capacity of tender tank	4,000 gallons.
Brake fittings	Westinghouse driving-wheel brake.

◆

THE SIBERIAN RAILWAY may be built across Northern Manchuria, according to a Pekin cable despatch, which states that the Chinese government has granted right of way under the condition that China can purchase this line 30 years after completion. The same despatch says that permission to build a branch line across Southern Manchuria was refused by the Chinese. The original location of the Trans-Siberian railway departed from the present line at Lake Baikal and cut across Northern Manchuria, directly to Vladivostock, instead of following the more northerly and crooked Amoor River. The saving in distance by the southern line would be about 500 miles between Lake Baikal and Vladivostock. This is apparently the right of way referred to as granted. What Russia wants, and will doubtless somehow obtain in the near future, is a branch from this line, at about Petung, south to the Gulf of Pechili, and to a port open at all seasons. The distance from Petung to Port Arthur is only about 500 miles, or about 150 miles more than from that point to Vladivostock. This is doubtless the branch through Southern Manchuria which the Chinese refuse, for the present.

◆

THE TENNESSEE CENTENNIAL EXHIBITION, which is to be held in Nashville from May 1 to Nov. 1, 1897, has opened an Eastern headquarters at No. 229 Broadway, New York, under the direction of Mr. Algar M. Wheeler, Commissioner for the Eastern States, where intending exhibitors may obtain all necessary information. A handsome illustrated circular has been printed by the management, giving views and descriptions of the buildings, and the "Centennial News Bulletin," a finely printed four-page sheet, is issued regularly from Nashville by Mr. Leland Rankin, chief of the Bureau of Promotion and Publicity. The illustrations in the "News" of Sept. 10 show the condition at that date of a number of the principal buildings. From the appearances of the photographs we should judge it likely that the promise made by the management to the effect that all the buildings will be completed three months before the opening day will be kept. The exterior of some of the buildings is practically completed already. The most remarkable building of the exhibition will be the Fine Arts Building, which is a reproduction of the Parthenon in Athens. It will occupy the "Acropolis" of the exhibition, and the other buildings will be grouped around it.

◆

THE NEW MOGUL FREIGHT LOCOMOTIVES built by the Schenectady Locomotive Works, Schenectady, N. Y., for the New York, New Haven & Hartford R. R., are particularly noticeable for the great length of cylinder stroke (28 ins.) and the great boiler capacity, the huge wagon-top end extending nearly to the smokebox. The general dimensions are as follows:

Driving wheels	5 ft. 3 ins.
Truck wheels	2 " 9 "
Driving axle journals	9 × 12 ins.
Driving wheel base	15 ft. 2 ins.
Total wheel base	23 " 3 "
Weight on drivers	124,400 lbs.
Weight, total	144,200 "
Cylinders	20 × 28 ins.
Steam ports	1[illegible] × 20 "
Exhaust ports	3 × 20 "
Boiler, diameter of first ring	5 ft. 2[illegible] "
Boiler pressure	190 lbs.
Firebox, length	9 ft. 0⅛ in.
" width	3 " 4¼ "
Grate area	30.22 sq. ft.
Tubes; number, 312; diameter	2 ins.
" length	12 ft. 0 "
Heating surface, tubes	1,946.72 sq. ft.
" " firebox	164.38 " "
" " total	2,111.10 " "
Capacity of tender tank	4,500 gallons.
Capacity of coal space	20,000 lbs.

◆

AN ELECTRICAL OSCILLATOR has just been patented by Nikola Tesla for transforming either direct or alternating currents into electrical vibrations of very high frequency. A number of inventors have been at work along this line chiefly because a high frequency current is believed to be the main requirement necessary to make vacuum tubes of practical use in electric lighting. There are also other uses to which a successful high frequency machine can be put, such as the production of ozone and of Roentgen phenomena, and all purposes for which a Ruhmkorff coil is now employed. The "Electrical Review" publishes an interview with Mr. Tesla in which he states that the invention is for use with ordinary electric lighting circuits and that the machine is simple in construction and can be manufactured at small cost.

◆

A NEW CLASSIFICATION OF THE EARTH'S SURface has been devised by Prof. Hermann Wagner, of Gottingen, one of the most prominent of the geographers of Germany. He divides the total area of the surface of the globe, above and below sea level, into five regions, which may be tabulated as follows, using sea level as the datum:

Regions.	From.	To.	Mean elevation or depres'n, ft.	Percentage of total area.
Culminating, above	+ 3280	......	+ 7.200	6.
Continental plateau	+ 3280	— 656	+ 800	28.3
Continental slope	— 656	— 7544	— 4300	9.
Oceanic plateau	— 7544	— 16.400	— 13.500	57.3
Depressed area, below.	......	— 16.400	— 20.000	3.

He places the mean elevation of the earth's crust at a depth of 7,500 ft. below the actual sea level; and he figures that of the total area land occupies 28.3% and the sea 71.7%; or a ratio of 1 land to 2.54 water.

STEEL PORTABLE VOTING BOOTHS have been used in New York city for the last three years. They are owned by the Buffalo Steel House Co. and rented for $90 per annum; the company has to move and store the houses, keep them clean and to do all the heating and lighting. These booths measure 12 x 28 ft., weigh about 3,000 lbs. each, and have six voting compartments with all the necessary room for transacting business. They replace the old wooden booths and have given general satisfaction.

A SAMPLE WAREHOUSE, for exhibiting American products of various kinds, is to be opened at Caracas, Venezuela, under the auspices of the National Association of Manufacturers of the United States. The concession obtained from the Venezuelan government permits the entry of goods for exhibit free of duty, with the dues to be paid only in case of actual sale. The Association, with its headquarters at 1751 North Fourth St., Philadelphia, issues a circular of information describing the building proposed for the permanent exhibition, with a plan of the spaces allotted for goods; and this circular also briefly sets forth the population, area and products of Venezuela, and the possibilities of trade with that country.

THE SMOKE NUISANCE is now being attacked by the cities of Buffalo and Kansas City. In Buffalo the aldermen passed an ordinance which the mayor has vetoed on the ground that it is not effective for the purpose for which it is framed, and that it will put undue burdens upon manufacturers. He recommends that a new ordinance be framed which will better meet the requirements of the situation. In Kansas City the matter is being taken hold of by a "Smoke Abatement Association," which has framed an ordinance for consideration by the city council. It is modeled after the one now in operation in St. Louis, which has proved to be very efficacious in diminishing the smoke from large chimneys.

THE PRODUCTION OF COAL IN OHIO in the year 1895, according to the annual report of Hon. R. M. Haseltine, Inspector of Mines, showed a substantial increase over that of 1894. The report gives the year's production as 13,683,879 tons, an increase over the preceding year of 1,773,660 tons. The increase in lump coal is 1,349,231 tons; in nut coal 113,755, and in pea and slack 310,674 tons. The unusual percentage of gain in lump coal is ascribed to the increased use of mining machines and the adoption of improved methods in mining. Of the year's production, 3,120,456 tons were mined by machinery, an increase of 564,990 tons as compared with 1894.

The average time worked is given at 156 days as against 132 days during the preceding year. Four hundred and forty-seven hands were employed in operating the machines and 3,374 hands in blasting down and loading the coal after it has been undermined by the machines.

There are 1,187 mines in the State—424 employ ten men and upward and 763 employ a less number. Of the entire number of mines, 1,097 were in operation during the year. The number of persons that found employment in and about the mines during the year was 22,416 miners and 6,582 day hands, as against 25,163 miners and 6,330 day hands during 1894. Deducting from the whole number of miners employed those who were engaged in operating mining machines, there were 18,645 miners employed as pick miners, a decrease of 3,863 as compared with 1894.

BOOK REVIEWS.

A TEXT BOOK ON SHADES AND SHADOWS AND PERSPECTIVE.—Prepared for the use of Students in Technical Schools. By John E. Hill, M. S., M. C. E., Associate Professor of Civil Engineering, Brown University. Second edition, revised and enlarged. New York, John Wiley & Sons; London, Chapman & Hall, Ltd. 1896. 8vo; cloth; pp. 101, with 12 folding plates. $2.

This text book is designed to furnish a short course in shades and shadows, and one-plane perspective, for students who have studied the elements of descriptive geometry. Prominence is given to the fact that the subjects treated are branches or applications of descriptive geometry, and follow that subject in logical sequence. For this second edition the book has been thoroughly revised and in the main re-written. We believe it will be found a very satisfactory text book for technical schools. The author's style of treatment is very clear and concise, and the 52 illustrations in the folding plates are well executed.

WEALTH AND PROGRESS OF NEW SOUTH WALES, 1894.—By T. A. Coghlan, Government Statistician. Eighth Issue. Sydney, N. S. W., Charles Potter, Government Printer. 8vo.; 1,021 pp.

This document briefly sketches the history, physical geography, geology, fauna and flora, and the political, financial and commercial growth of New South Wales. The list of contents also covers mineral, agricultural, industrial and educational statistics, together with much other matter relating to progress of this section of the world. The period covered by the tables is limited to ten years; but the reader is referred to the "Statistical Register" for more detailed figures.

MATHEMATICAL TABLES.—Consisting of Logarithms of Numbers, 1 to 10,800, trigometrical, nautical and other tables. Edited by James Pryde, F. E. I. S. New Edition. New York, D. van Nostrand Co. 8vo.; 454 pp. $1.75.

This edition is greatly enlarged and the tables of logarithms of numbers, logarithmic sines, tangents and secants, and those of natural sines, cosines, versed sines and chords, tangents and cotangents, secants and cosecants, and of circular arcs, have been carried to seven decimal places and rearranged so as to be more convenient for use. The greatest care has been observed in making these tables accurate, and to secure this end they have been collated with six of the best sets of tables known. The price remains the same as for the old edition.

A DICTIONARY OF GEOGRAPHIC POSITIONS.—Bulletin No. 123, U. S. Geological Survey. By Henry Gannett, Chief Topographer, Washington, D. C., Department of the Interior, U. S. Geological Survey. 8vo.; 183 pp. $0.15.

This will be found an exceedingly useful book of reference to many engineers and land surveyors. For some years past the Division of Topography in the U. S. Geological Survey has been engaged in compiling positions determined within the United States which are believed to be sufficiently accurate for use in preparing its maps. It is placed before the public at the very modest price stated, and the list covers nearly 10,000 positions, with the latitude and longitude expressed to hundredths of a second, together with the authority. These positions are arranged by states, and within states by "square degrees," or the quadrilateral limited by consecutive parallels and meridians. But an alphabetical index covering all the positions noted enables any one to readily find those marked. A short sketch of the several authorities used in the compilating of the list is given. A dictionary of altitudes has also been compiled by Mr. Gannett, and is issued as Bulletin No. 76, and sold for 25 cents by the Geological Survey.

DES INGENIEURS TASCHENBUCH.—Herausgegeben vom Akademischen Verein "Huette." 16th edition. Berlin, 1896. Wilhelm Ernst & Sohn. 2 vols., 7 x 4½ ins.; pp. 984 and 618. Price in Germany, bound in leather, 16 marks = $4.

The standard German engineers' "pocket-book" has now grown too large for one pocket, and it has been divided into two volumes. "Huette" differs from the American engineers' pocket-books, not only in being larger, but in its methods of treatment. It devotes considerable space to descriptions of apparatus, the chapter on steam boilers, for instance, covering 103 pages, and including cuts of all the principal styles used in Germany. It is less elementary than the American books, assuming a considerable amount of mathematical knowledge on the part of the user. The subject of mechanics begins with velocity and acceleration, instead of with force, and equations involving a knowledge of the differential calculus are employed in its discussion. The second volume is chiefly devoted to engineering practice in the departments of railways, buildings, bridges, steam vessels, furnaces, flour mills, paper making, etc. The work is an invaluable reference book to any engineer who has an acquaintance with the German language.

UNIVERSAL DIRECTORY OF RAILWAY OFFICIALS, 1896.—Compiled from Official Sources by S. Richardson Blundstone, Editor of the "Railway Engineer." Directory Publishing Co., 8 Catharine St., Strand, London, England. Cloth; 8vo.; pp. 375; 10 shillings ($2.50).

This is the second edition of the directory which was reviewed in our issue of Nov. 28, 1895, and it is stated that about 150 railways and 32 pages of matter have been added in this edition. Some of the omissions and inaccuracies noted in the review of the former edition reappear now, Colombia being credited only with the Girardot Ry., and no mention being made of the newer and more important lines. Even the Panama Railway is again omitted. One of the weak points in this, as in the first edition, is the treatment of the railways of the United States, and it is difficult to understand what system of selection has been employed, several small lines being included, to the exclusion of some of the great trunk lines. It also mixes up the Knoxville & Ohio (65 miles) with the Southern Ry. (4,649 miles), by which it is leased, and gives the former little line a long list of officers of the latter line. These defects are doubtless due to a lack of knowledge of the railway systems of this country, but they greatly detract from the usefulness of the work, in fact the directory of American railway officers would be of little use in this country, where several much cheaper and far more complete and accurate directories are regularly issued. The information respecting the railways of Great Britain, the British colonies and European countries is naturally pretty complete, and in the whole the book is probably as complete and accurate as could be expected, with the exception of the United States section, the omissions in which are glaring and inexcusable. The volume is well and clearly printed on a good quality of paper (though the arrangement and type are somewhat confused in style), and it is strongly and compactly bound.

IRON MAKING IN ALABAMA.—By William B. Phillips, Ph. D. Published by the Alabama Geological Survey, Eugene Allen Smith, Ph. D., Director, Montgomery, Ala. 1896. Pamph.; 8vo.; pp. 164.

The development of iron making in Alabama in the ten years from 1880 to 1890 was one of the most remarkable events in the history of the iron trade. Not less remarkable has been the progress of the last three years in cheapening the cost of production to such a point that it has been possible when freight rates were favorable to ship a portion, although a small one, of the product of the state to England and other foreign countries to compete with English iron. The pamphlet before us was written by Dr. Phillips for distribution by the Geological Survey, and it gives a very complete account of the present status of the industry chiefly from the standpoint of the miner of the raw materials used in iron making. The growth of the manufacture of coke pig iron in the state is well shown in the following figures: Tons of 2,240 lbs.—1876, 1,262 tons; 1880, 35,232 tons; 1885, 133,808 tons; 1890, 718,383 tons; 1892, 835,840 tons; 1894, 556,314 tons; 1895, 835,851 tons. The production is now about 10% of the total iron production of the United States. The pamphlet is largely devoted to a description of the ores, fuels and fluxes found in the state, then follows a directory of the furnaces, rolling mills, etc., with a brief description of each, and a number of short papers by different writers on the grading of Southern pig iron, the market for Alabama pig, etc. The papers on the grading of pig iron should be read by all who are interested in the purchase or use of pig irons for foundry purposes. Dr. Phillips shows clearly the troubles which arise from the present method of having eleven different grades for Southern pig irons, and recommends that they be reduced to six, having chemical analyses as follows:

	Silicon.	Combined Carbon.	Sulphur.
Silvery irons.. ..	5 to 6	0.10 to 0.30	0.01 to 0.04
Soft irons..	3 to 5	0.20 to 0.60	0.01 to 0.05
Foundry irons ..	2 to 3	0.30 to 0.90	0.01 to 0.07
Gray forge..	1 to 2	0.40 to 1.25	0.04 to 0.09
Mottled..	0.6 to 1	0.50 to 1.80	0.06 to 0.11
White..	0.1 to 0.6	1.00 to 2.50	0.08 to 0.30

He strongly favors, of course, the grading of irons by analysis and condemns the old method of grading by fracture.

METALLIC STRUCTURES, CORROSION AND FOULING AND THEIR PREVENTION.—A Practical Aid-Book to the Safety of Works in Iron and Steel, and of Ships; and to the Selection of Paints for Them. By John Newman, Assoc. M. Inst. C. E. London, E. & F. N. Spon; New York, Spon & Chamberlain. 12mo.; pp. 374. $3.50.

The author appears to be a professional book-maker rather than an engineer. The title page gives the names of five other books which he has written, one of which has a rather taking title, "Scamping Tricks and Odd Knowledge Occasionally Practised upon Public Works;" the others being on earthwork slips, concrete, cylinder bridge piers, and foundations. What special qualification the author has for writing a book on the subject of corrosion is not apparent, except in the following note from the preface.

> The author, having had his attention specially directed during many years, to the subject of corrosion and fouling and their prevention, has placed his experiences on record, and that of others in all parts of the world, to whom he offers his acknowledgments, and also to the editors of the various technical journals mentioned.

From an examination of the book itself it would appear that the author's method of book-making is to have a box or drawer into which for several years he puts clippings or notes of the subject upon which it is his intention to write, and then in due time to arrange the matter into shape for publication in the best way that he can, with the least labor possible in studying the subject or in arranging the matter in logical and literary form. There is a "long-felt want" for a good book on the subject of corrosion; the author has recognized the want, and attempts to fill it with a "pot-boiler." Of course the book contains a great quantity of useful information, clipped from various sources, but the useful matter is so hidden amongst a mass of imperfectly digested, if not useless, stuff that a great effort is required to find it. For instance, in searching to find what is the author's opinion on the subject of the relative corrosibility of different grades of wrought iron, on page 31, we find:

> The greater the purity, homogeneousness and freedom from foreign matters of the metal, other conditions being similar and in accordance with specified requirements relating to strength, the less will be the corrosion.

On p. 34 we find what appears to be a contradiction of the above:

> Hard and crystalline irons are generally considered to be less oxidable than ductile or fibrous irons.

The following sentences, also from p. 34, are examples of the characteristic style of the author:

> In steel, uniformity can be approached more than in iron; however, the cinder in iron and the scale of steel are different. The former is a dielectric glassy substance and has no corrosive influence, while the scale produced in rolling steel has a very deteriorating effect, as it is a magnetic oxide negative to the steel, and therefore corrosion is rapid, as also if such scale is rolled into steel plates. Professor Kick, of Prague, after many experiments, which he only regards as indicating the probable general rule, not as proving it, with nitric, sulphuric and hydrochloric acids and their cerubinations, with mordants composed of the salts of copper, etc., found that soft and fibrous iron of good quality, also fine grained iron, when attacked by the acid, is uniformly so, and with a limited elimination of the carbon, the surface retaining a dull lustre, a few incised specks and cinder-like holes being only observable. Coarse-grained iron and hot-short iron were found to be more powerfully attacked.

THE AMERICAN TRANS-CONTINENTAL ARC, as surveyed by the U. S. Coast and Geodetic Survey, has been completed. It lies along the 39th parallel, north latitude, and extends from a point near Cape May, on the Atlantic, to a point above San Francisco, on the Pacific coast. According to the measurements made the distance, reduced to sea-level, is 2,625.8 miles; and from these measurements the radius of the 39th parallel is yet to be determined. While this survey has cost about $1,000,000 in the aggregate, the longest base-line heretofore run is that across India, about 1,000 miles long. As compared with the radius of the 39th parallel, as given by Bessel, of Germany, this arc as measured is 111 ft. in error; and according to the figures of Andrew Clarke, of Glasgow University, it is 98½ ft. in error. But the Bureau claims that these variations are due to errors in previously established standards.

COMPRESSED AIR FOR OPERATING WAR-SHIPS is an innovation; but the U. S. Monitor "Terror" is so equipped and is said to be the only war-ship in the world that uses this power for turning its turrets, working the guns and steering the ship. Compressed air has been substituted for steam, or hydraulic power, because a leak in the pipes is not dangerous, and no exhaust pipes are required, as with both of the others. The "Terror" has two air-compressing engines, which can, singly or together, supply sufficient air at a pressure of 125 lbs. per sq. in. to operate both turrets. The air is carried to engines in each turret having 8-in. cylinders and 14-in. stroke, of about 40 HP. each. The shell-hoist is operated by another pneumatic cylinder, and the ramming is done by the same power. Compressed air also elevates or depresses the gun, and two pneumatic cylinders control the recoil. A similar engine is connected with the steering-gear, though a 5 HP. electric engine is also fitted for the same purpose. The "Terror" has passed her trial stage and the machinery operated by the compressed air has been found to work satisfactorily.

THE USE OF ELECTRICITY ON THE "FRAM," Nansen's exploring ship, is noted by the "Elektroteknish Tidsskuft," of Christiania. The dynamo was operated by a windmill and every puff of wind was utilized to load the accumulators. The current generated was used for incandescent and arc-lamps, and for firing the mining shots in clearing the "Fram" from ice. In extremely cold weather the solution used in connection with the accumulators froze solid, but the acid-blended ice was still useful in operating the accumulators and the cells were used until the cog-gearing in the windmill wore out.

THE WAR DEPARTMENT ESTIMATES, for the next fiscal year aggregate $52,875,638. The chief items in this estimate are as follows: Pay of army, $13,522,880; army subsistence, $1,659,837; quarter-masters' supplies, $2,200,000; army transportations, $2,500,000; clothing, $1,100,000; ordnance department, $1,131,000; military posts, national cemeteries and national parks, $1,558,380; national soldiers' homes, $3,443,214; rivers and harbors, $5,349,000. In regard to coast-defences, Secretary Lamont reports as follows: Within the last four years, 17 out of 21 12-in. emplacements, 55 out of 60 10-in. emplacements, 20 out of 25 8-in. emplacements, 14 out of 16 rapid-fire gun emplacements, and 92 out of 156 12-in. mortar emplacements, have been entirely provided for; while much work has also been done in the same time on those previously provided for. As nearly as can be gathered from the report, the government has now completed, or under construction, 71 12-in., 112 10-in. and 88 8-in. modern breech-loading rifled guns, and 109 12-in. rifled mortars, besides smaller guns. The all important question of gun-carriages has been practically settled and disappearing and non-disappearing carriages of an acceptable type are being furnished.

A SWORD FISH pierced 13 ins. of Oregon pine, forming part of the hull of the brigantine "Irmgard," on the late passage of that ship from Honolulu with a cargo of sugar. The sword passed through the 5-in. planking on the port bow and the 8-in. skin planking behind it, protruding 1 in. into the hold of the vessel. The planks were split for about 1 ft. each way, causing a leak. We give the above on the authority of the San Francisco "Examiner."

STEEL FERRY-BOATS, with twin-screws at both ends, are being built for the Pennsylvania R. R., to ply on the North River, from Jersey City to 23d St., New York city. The first of these boats, the "Pittsburgh," was launched from the Cramp shipyard on Oct. 17. The dimensions are—length over all, 206 ft. and 184 ft. between rudder-posts; moulded beam, 46 ft., and over guards, 65 ft.; average depth of hold, 15 ft. The hulls are made of steel with water-tight compartments, and there are two 3-cylinder compound engines with cylinders of 20, 32 and 32 ins. diameter and 24-in. stroke. Each engine will operate two screws 8 ft. 3 ins. in diameter on a continuous shaft. Water-tube boilers are used, with a working pressure of 200 lbs. A sister boat, the "St. Louis," will soon be launched from the yard of B. Hillman & Co., in Philadelphia.

THE MOST SERIOUS RAILWAY ACCIDENT of the week was a head collision of passenger trains on the Florida Central & Peninsular R. R., at Swansea, Ga., Oct. 14. The southbound train had orders to pass the northbound train at Swansea, but the engineman read this as Sweden, a station 30 miles beyond. When the conductor found the train was running past Swansea he started to signal the engineman, but just at that time the collision occurred. Both engines were wrecked and the combination mail and baggage car of the southbound train was overturned and set on fire. The baggage master and mail clerk were burned to death and a brakeman who was crushed between the cars was also burned to death.—— In a collision between a locomotive and an electric car at Hazleton, Pa., Oct. 14, three men were killed and nearly 30 injured, some fatally.

THE LOSS OF THE STEAMER "ARAGO" occurred Oct. 20 at the entrance to the harbor of Coos Bay, Oregon, during a heavy fog, and 12 persons (passengers and crew) were drowned. The vessel was owned by the Oregon Coal & Navigation Co., and was a steel steamer built by the Union Works, of San Francisco. It was 200 ft. long, 30 ft. beam, 16 ft. deep, of 947 tons gross tonnage.

THE FALL OF A CONCRETE DOME ROOF at the University of Virginia, Charlottesville, Va., on Oct. 19, resulted in the death of two men and the serious injuring of three others. The roof was a new one and the men were removing the falsework.

THE COLLAPSE OF A BRIDGE under a 15-ton steam roller occurred Oct. 14 at Watertown, N. Y. The engine was crossing the Knowlton bridge over Black River, when the bridge broke and the engine fell 30 ft. to the ground below, killing the engineman.

THE FLOOD PROTECTION DIKE at Corning, N. Y., has proved its efficiency during the recent freshet in the Chemung River. There were three unfinished places in the dike, but the Ferguson Contracting Co. kept gangs of men at work all night to fill the gaps. It is said that this is the first time that the Fifth Ward has not been flooded in time of high water.

EXCESSIVE SPEED OF ELECTRIC CARS is causing trouble at Hartford, Conn., and the Hartford Street Ry. Co. has been notified of the following results of an investigation made by Mr. A. W. Gilbert, City Electrician:

	No. of Readings.	Per cent of total No.
Under 8 miles per hour..................	5	3.0
8 to 10 " " "	14	8.6
10 to 12 " " "	47	29.0
12 to 14 " " "	35	21.6
14 to 16 " " " "	36	22.2
16 to 20 " " "	17	10.5
Over 20 " " "	8	4.9

THE BOSTON SUBWAY is to be leased to the West End Street Ry. Co., at an annual rental of 4.75% on its cost, which is not to exceed $7,000,000, the lease extending for 20 years. As the city pays a considerably less rate of interest (between 3 and 3½%) the difference between rentals and interest charges will constitute a sinking fund which will eventually pay off the capital borrowed by the city for the subway construction.

THE POWER OF LABOR UNIONS over public officials has recently been shown in Detroit. The board of supervisors is about to erect a new county building, and it received a letter from Mr. Garland, president of the Amalgamated Association of Iron and Steel Workers, asking that the contract for the iron and steel work be kept from the Carnegie Steel Co. In his letter he says:

> Since the memorable struggle with the company they have been cutting wages of the men in their employ and the market price of the material, and thereby making it harder for us to secure fair wages from union manufacturers. Even now they have demanded a reduction of their men, to take effect January 1. At the same time they are enjoying the benefits of a trust and holding up the price to $4 over a normal profit.

There appears to be a contradiction between the two statements that the company "is cutting the market price of the material" and that it is "holding up the price to $4 over a normal profit," but if so the supervisors seem to have overlooked it and they passed a resolution to the effect that none but union-made iron and steel work be used in the county building.

EIGHT DYNAMOS OF 560 K-W. each have been erected and started in the power-house of the Niagara Falls Hydraulic Power & Mfg. Co. in the gorge below the Falls. A description of this plant was given in our issue of March 26, 1896. The eight dynamos are driven by four Leffel turbines. The company expects to deliver power to the new aluminum works of the Pittsburg Reduction Co. in about two weeks.

BELGIAN PAVING BLOCKS to the number of about 15,000 have been imported by the New York Department of Public Works for use upon some streets of heavy traffic. The claim is made that they are more homogeneous in structure and wear better than blocks of native stone.

SEWER FLUSHING AT ROCHESTER, N. Y., has been discontinued. It seems that the work was at one time done by the Board of Health, which for some reason discontinued it. The Executive Board then took up the work, although not coming within its domain. Money for the work not being provided by the Common Council the Board has been obliged to discontinue the flushing.

LIMITATIONS OF THE CITY ENGINEER of Providence, R. I., are being considered by the Board of Aldermen of that city. It is proposed to restrict the engineer from doing outside work. The matter has been laid over until the last of October.

THE DRAWBAUGH TELEPHONE AND TELEGRAPH Company has applied to the Board of Electrical Control, of New York city, for a franchise to establish a telephone system. This company, of which Mr. J. R. Bartlett is president, contested for years the validity of the claims of Alexander Graham Bell as the inventor of the telephone and it is still engaged in legal controversy. As all attempts failed to establish Daniel Drawbaugh as the prior inventor, a bill is now before Congress, but not yet passed, asking that the Drawbaugh Company be permitted to use similar appliances to those now claimed by the Bell Company. It is in the hope that this bill will be favorably acted upon that the present company was incorporated on July 25, 1895.

INCRUSTATIONS IN WATER-PIPE, says "Le Genie Civil," were recently removed by fire, at Setif, as follows: Three pipes had been reduced in diameter from 1½ to 2¾ ins. by incrustation, and immersion in a bath of diluted hydrochloric acid had failed in useful result. Finally two lengths of pipe were placed on the ground parallel to each other, and 6½ ft. apart, and on these layers of 15 pipes were placed, each layer at right angles to the one below it, until there were 7 or 8 layers. Combustible material was filled in between the pipes and fired; and when the pipes were cooled they were easily scraped out and cleaned. Out of 137 pipes only 6 developed defects causing their rejection after the firing process, and the cost was about 3 cts. per lineal foot of pipe.

AROUND THE WORLD IN 33 DAYS is the possible pace set by Prince Hilkoff, the Russian Imperial Minister of Ways and Communication, now officially studying American railway methods. To make the circuit in this time modern fast ships and railway trains are alone considered; but with these available on the routes specified he gives the time as follows: New York to Bremen, 7 days; Bremen to St. Petersburgh by rail, 1½ days; St. Petersburgh to Vladivostock, by rail at 30 miles per hour, 10 days; Vladivostock to San Francisco, via Hakodate Straits, 10 days; San Francisco to New York, 4½ days. The present shortest time for circuiting the globe is given as follows: New York to Southampton, 6 days; Southampton to Brindisi, via Paris, 3½ days; Brindisi to Yokohama, via Suez, 42 days; Yokohama to San Francisco, 10 days, and San Francisco to New York, 4½ days, or 66 days in all.

THE WATER SUPPLY SYSTEM OF SALT LAKE CITY, UTAH.

By W. P. Hardesty, C. E.

(With inset.)

Salt Lake City is exceptionally well situated to secure a good supply of pure water at moderate cost. The Wasatch Range of mountains lies close to the city on the east, and all along its western slope issue streams of pure mountain water, well fed by the snow, which lies on the highest peaks of the range till far into the summer. The creeks immediately contiguous to the city, and which were naturally first turned to for water, are:

(1) City Creek, which comes in from the northeast and enters the city and flows through the north side. (2) Emigration Creek, which comes in from the east. (3) Parley's Creek, which issues from the mountains southeast of the city. These creeks flow naturally westward through the city, emptying into the Jordan River, but their channels have been greatly changed and converted into irrigation canals, flumes, etc.

The water from all these creeks can, within a short distance from the town, be diverted so as to secure an all-gravity supply with an almost unlimited pressure. On account of the range of elevation, the north central, northeast and east central parts of the city naturally compose a zone for a high-line system, while the remainder can be covered by a low-line supply.

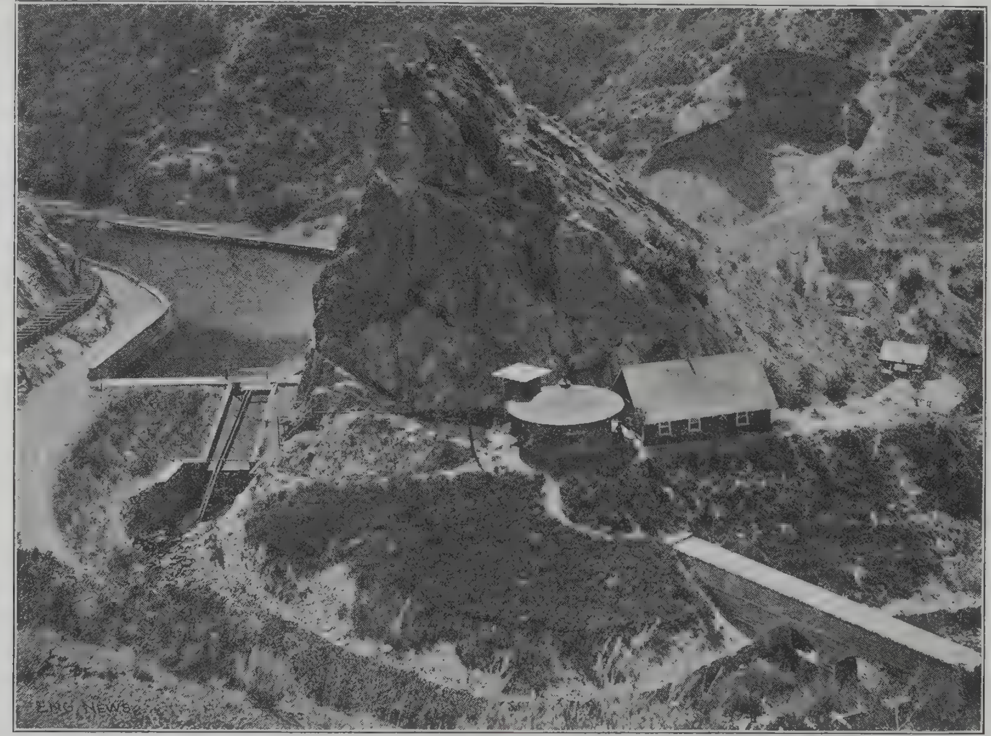

FIG. 1.—VIEW OF DAM, SCREENING TANK AND CULVERT AT HEAD OF PARLEY'S CREEK CONDUIT, SALT LAKE CITY.
A. F. Doremus, M. Am. Soc. C. E., Engineer.

The water supply system has always been owned by the city. The population of Salt Lake City increased from 20,768 in 1880 to 44,843 in 1890, and is now estimated at 50,000.

City Creek Supply System.

This creek, being much the nearest and most available stream, was naturally turned to first for water for irrigation as well as domestic use. Indeed, the Mormons tapped this creek with a small irrigating ditch on the very day they arrived in Salt Lake Valley, July 24, 1847. All water brought by the city for domestic use came through open ditches, or from wells, until about the year 1872, when the creek was tapped by a pipe line. Wooden pipe was proposed at first, but cast-iron was soon substituted. This cost, then, about $100 per ton delivered in Salt Lake City. A 20-in. pipe was used for 1,900 ft., and a 16-in. pipe for 1,450 ft. more, which brought the line to the center of the city, no water being then drawn from it on the way down. In 1888, a line was taken out nearly one-half mile farther up the stream. The water is diverted by a weir, and after passing through screens for excluding leaves and drift is passed by a short tunnel through a projecting ridge in the valley to a brick tank on the creek below, used for a settling basin. This tank is divided into two compartments, so that either can have the water drawn off and be cleaned when necessary. It has a capacity of 220,000 gallons. From the tank a pipe line leads down the canyon to connect with the first pipe line. About 100 ft. of this pipe is 30-in. and the rest 24-in., reducing to 20 and 16 ins. in the first line.

It is told as a fact that Brigham Young and his lieutenants gave the pipe this diminishing size, from 30 to 16 ins., with the firm opinion that the momentum of the water (it was to gradually increase in velocity) would permit of this reduction in pipe cross-section.

In 1889 the 20th Ward pipe line was built. This takes water at about 130 ft. higher elevation than the low line. It consists of a 12-in. wooden pipe, wound spirally with flat bands and well tarred. On leaving the canyon bed, the pipe is changed from 12-in. wood to a 6-in. cast-iron (which climbs the side hills and runs east on 6th St.), and to an 8-in. kalameine pipe. This pipe line supplies the district between South Temple St. and 6th St., and from State St. east.

The high line supply from City Creek is taken out about 2½ miles above and nearly 500 ft. higher than the low line, and supplies the highest part of Salt Lake. The main is of 12-in. cast-iron, and just below the brick tank of the low-line system a Y is put in and a branch run up each side of the canyon onto the high ground. The branch on the east supplies the 13th St. system, which includes the district between 6th and 13th Sts., and between State and O Sts.

The only reservoir completed and now in use on the City Creek system is the one on Capitol Hill, on the west side of the canyon, fed by the west branch of the high line. This is 100 × 200 × 14 ft., is lined with concrete and cement; cost over $20,000 and holds 2,050,000 gallons.

The capacity of the pipes taking water from City Creek is about 14,000,000 gallons daily. The average minimum flow of the creek is about 7,000,000 gallons daily, with 4,000,000 gallons as the least flow recorded, in 1889. The natural flow has been much increased since then by tunneling and developing the springs and underflow.

Great care is taken in the canyon of this stream to guard against pollution. During the summer season the creek is regularly patrolled by watchmen in the employ of the city. The creek channel has been greatly improved by straightening and by rip-rapping its banks with stone. In this manner most of the vegetable matter and the debris have been excluded from the stream. The drift that does get into the stream is regularly cleaned out each season. The water, however, is hard, on account of the carbonates of lime and magnesia, which also cause concretions, particularly in dead ends of pipes. Some of the very small mains used in this system are at an extreme disadvantage on account of these incrustations, being often nearly closed.

Emigration Creek Supply.

This creek was tapped after the city had grown beyond the capacity of the City Creek supply. In 1890 a 12 and 14-in. kalamein iron pipe was laid from the creek just above the mouth of the canyon to a relief tank on the east bench in the city. This line is over three miles long and has a fall of about 300 ft. A trench 10 ft. wide and nearly 200 ft. long was dug across the bottom of the canyon with the intention of putting in a submerged dam and raising the water to the surface. It was found that the bed-rock in the lowest part was much deeper than was expected, and after going down 27 ft. the water had increased so fast that three pumps could not handle it, so this plan was abandoned.

A supply of about 800,000 gallons daily is obtained from that portion of the underflow reaching this trench that rises to the level of the inlet to the pipe here, near the top of the trench.

The natural summer flow of this creek is quite small and is rendered impure by the many flocks of sheep driven through the canyon. As a means of increasing the flow a tunnel was driven into the hill on the south side of the canyon at this same site. This tunnel is about 4½ ft. wide by 6 ft. high, and reaches in 306 ft. It cost about $5 per lin. ft. A flow of excellent water, estimated at 800,000 gallons daily, was thus developed. To secure the underflow it is proposed to start a tunnel about one-half mile down the canyon, at the mouth, and run up the canyon to the site of the dam. A ledge of rock extends diagonally across the valley here, though rather deeply buried in the center. It is believed that by constructing the tunnel with the head on the upper side of this ledge and at a sufficient distance below its top, that the ledge, acting as a submerged dam, will collect all the water needed to be drawn off through the tunnel. Some borings have been made to define the profile of this ledge and ascertain the best location for the tunnel.

The conduit constructed is of 14-in. pipe, except about one mile of 12-in., used where the hydraulic grade is heavier. The crossing of Red Butte Creek (a small stream north of Emigration Creek) is made by laying the pipe in a box 16 ins. square inside. This box is very strongly built, and is packed with sawdust around the pipe. It spans the creek, having a mud sill as support at each end. The sides of the box are single, 8 × 16-in. pieces. The capacity of this pipe-line is about 3,000,000 gallons daily. It was built in 1890 and cost $51,000, of which the pipe and fittings cost about two-thirds, at the factory.

Parley's Creek System.

It was in 1889 that Salt Lake City took on a new growth—a genuine western boom, and it was soon seen that the water supply was totally insufficient. Both Emigration and Parley's Creeks were suggested as new sources of supply, and the construction of the former in 1890 was followed by that of the latter in 1891-92. The mouth of Parley's Creek is over two miles south of that of Emigration Creek, and as the supply lines from both run northwest to the same point, the waters could just as well be united opposite the mouth of Emigration Creek canyon, making one line serve for both from that point to the city. This was not done for the reason that there was immediate need for more water, which could be secured quickly and cheaply by constructing the Emigration Creek line, and also for the reason that it was thought that this supply would be sufficient for a while, which, however, was not the case.

The Parley's Creek conduit has a length of over five miles, and it was made of sufficient size to

carry the waters of Mill Creek, the next creek south of Parley's, The conduit can be extended on to this creek with an additional length of about two miles. This will probably be done when necessary. Parley's Creek is tapped at the mouth of the canyon, at Sentinel Rock, where the opposite walls approach and make a natural damsite. The head-works are shown by the two views, Figs. 1 and 2. The system consists of a settling basin, a stone dam, screen house and over five miles of 36-in. conduit. The conduit has a fall (of hydraulic grade line) of 0.16 ft. per 100, with a daily carrying capacity of 18,000,000 gallons.

The dam shown in detail by Fig. 3, on the inset sheet, is of concrete, with rubble masonry facing and cut stone coping, Portland cement being used. It has a water-way over its top and a 30-in. sluice underneath for passing surplus water. The crest of the spillway is 19½ ft. above the top of the foundation; its clear width is 12 ft., and the fall to the toe of the dam on the lower side is 20½ ft. Of this fall, 12½ ft. is down a 2 to 1 slope, and the balance of 8 ft. is a vertical drop, the water falling on an apron 13 ft. wide. The dam is 70 ft. long on top and the greatest width at the bottom is 34 ft., this being under the spillway.

The 30-in. sluice discharges the water near the bottom, and is controlled by a gate at the upper end. The upper side of the dam next to the spillway has a batter of 1 in 10, and the lower side of 1 in 2. The bottom width here is 18 ft., and the height, 22 ft.

The water is conveyed in a 36-in. cast-iron pipe, laid in a tunnel about 100 ft. long, and on the south side of the creek, from the upper side of the dam to the screening tank, both being at the foot of Sentinel Rock.

The tank, Fig. 4, consists of an annular settling basin, 3¼ ft. wide and 12½ ft. interior diameter, the water falling over the top of this into the circular discharge basin inside of it, the two basins being separated by an 18-in. wall, of an extra strong concrete, the parts being 1, 2 and 3. On top of this wall are the screens, through which all the water passes. This discharge basin is 9½ ft. by 16 ft. deep, and near its bottom the 36-in. outlet starts. The bottoms of both the settling and discharge basins slope in one direction toward a discharge pit, from which a 10-in. pipe leads for discharging sediment back into the creek. This pipe has a gate between the discharge basin and the pit. and one at the outlet to the latter. The screening tank is enclosed within a neat brick building.

From the discharge basin a 36-in. cast-iron pipe leads. The creek is crossed at once from south to north by a double stone culvert with 12-ft. arches, shown at the right of the view, Fig. 1. The pipe rests on concrete, which is carried halfway up its sides, the stone coping being all that is placed over its top. This pipe extends from the tank to the first manhole, a distance of 450 ft., and has a uniform ascending grade of 0.5% until the creek is crossed and then a grade of 3% to the manhole. This up grade is partly for the purpose of allowing sediment carried through the screens to deposit in the pipe, and when the inlet to the tank is closed and the discharge gate opened, the backward flow of the water in this pipe carries much sediment with it to be flushed out.

At the manhole begins the main conduit. This is a combination structure of concrete and brickwork, as shown by Fig. 5. The lower two-thirds is of concrete and the top one-third is of brickwork.

A special arch brick is used, having a depth of 6 ins., and but one ring is used. Where the conduit passes under a highway, an extra ring of common-sized brick is used over the 6-in. ring, to give added strength. The contract called for native cement for all the conduit, but after about ¾ mile had been built an agreement was made by which Portland cement was used for the concrete at the same price, the proportions of 1, 2 and 3 of the former being changed to 1, 4 and 5 of the latter. The bottom of the conduit, however, was still made with the native cement. Native cement, mostly Milwaukee or Utica, was used for all brickwork. The inside of the conduit is plastered with ½-in. of mortar of equal parts of sand and Portland cement. The maximum curvature for the conduit in the difficult work in the valley is 15°, while 3° and 4° curves are mostly used on the open ground.

Seven tunnels are used through the valley, ranging from 70 to 770 ft. in length, and with an aggregate length of 2,000 ft. These are used to go through the points of ridges. The material encountered was all earth. The summits above the tunnels range from 20 to 40 ft. The excavation was made 6 ft. high and wide enough to work in. Light cast-iron pipe is used through the two longer tunnels, amounting to 1,300 ft. in length, and the earth was backfilled around the pipe. It was deemed unsafe to use the concrete conduit here on account of a glacial movement of the earth, caused by its composition and by its being kept wet by seepage water.

Nearly one-half mile below the head is Dudler's gulch, which is crossed by a five-span arch culvert, shown by Fig. 6. Four of these are "blind" arches, and are of concrete with 12 ft. span, the arches being blinded with stone walls, while the center arch is of stone, of 14 ft. span and is open to pass the drainage.

The concrete arches are each 16 ins., and the stone arch 24 ins. thick on top, below the bottom of the conduit. The width of the blind arches is 18 ft.; the stone walls are each 2 ft. thick, leaving a 4-ft. open space between, which was filled with earth and stone spalls, well packed. The piers between arches are solid. The standard construction of conduit is used, but 18-in. stone walls are used on the sides in addition, while over the brick arch is a regular pavement of sand, concrete and cement.

The arch of the center opening, the belt courses and coping are of cut stone, the rest of the masonry of coursed ashlar, quarry-faced. Portland cement is used in all these extra structures, except for the brickwork. The conduit here is on a 15° curve. A 9-in. stone pavement is used under the center opening for the drainage.

At about three miles from the head, Emigration Creek is crossed, by an inverted siphon, shown in detail by Fig. 7. This is a 36-in. redwood stave pipe, with steel bands. It is 546 ft. long, 313 ft. of this length being under a head of 12 to 15 ft., while the crossing of the creek bed proper is under a head of 33 ft. for a distance of 87 ft. At each end of this latter crossing is a deep brick well, giving a vertical drop in the siphon of over 19 ft. Adjoining the well at the north end is a valve pit, with an outlet pipe, by means of which the well and thereby the siphon is drained off when desired. This siphon pipe is buried about 3 ft. under the bed of the creek. Red Butte Creek is crossed with a 6-ft. open arch culvert, with a grade 6 ft. above the creek, and with two 8-ft. blind arches.

At the intersection with 5th, 7th, 9th and 10th South Sts. the conduit is connected by lengths of 12-in. pipe with valve boxes, to be used for direct connection with the city pipe system when needed. The average cut made in open ground for this conduit was 8 ft., and 3 ft. is the least depth of covering over the top.

Brick manholes are placed every 800 ft. along the conduit. These have ventilators under the edges of the covers and a screen with ¼-in. meshes is placed below the cover of each manhole to prevent any large object that may get through the ventilators from falling into the conduit. The covers are provided with locks.

The ordinary sections of conduit cost $2.70 per lin. ft., while the contract price for wooden pipe, wrought-iron pipe and light cast-iron pipe were $3.45, $6.95 and $11.68, respectively, showing conclusively the economy of using the conduit in this case, to say nothing of its superior durability.

The Parley Creek conduit system was designed and built under the supervision of Mr. A. F. Doremus, M. Am. Soc. C. E., who was the city engineer from 1890 to 1894. Dubois & Williams, of Denver, Colo., were the contractors for all the work, except excavation and backfilling. In design and in the excellent and substantial character of construction, this system will compare favorably with any to be found in this country.

The entire cost of this system was $181,000, of which $34,000 went to contractors for excavation, etc., $117,000 for the masonry and constructed parts of the system, including pipes; $10,000 for engineering and $4,000 for inspection; right of way and additional work by other parties on the conduit taking up the balance.

The water from the conduit, and from the Emigration Creek pipe line, can be discharged into the relief tank, Fig. 8, on the east bench on the line of 1st South St. The pressure from the latter line must be relieved here before being turned into the low line system, as there is a fall of nearly 300 ft. from its head. The tank is 20 ft. in diameter and 14⅔ ft. deep. From the west side are projected two pipe lines, one of 24-in., leading to the 20th Ward pipe system, the other of 30-in., leading to 13th East St. reservoir, from there to be conducted into the low line supply system of the city. At present, however, water from the Emigration Creek line is not discharged into the relief tank at all, but is continued on past it and west on 1st South St. to supply the district between 8th and 13th East Sts. without relieving the pressure. An overflow pipe leads from the tank at a higher elevation than the

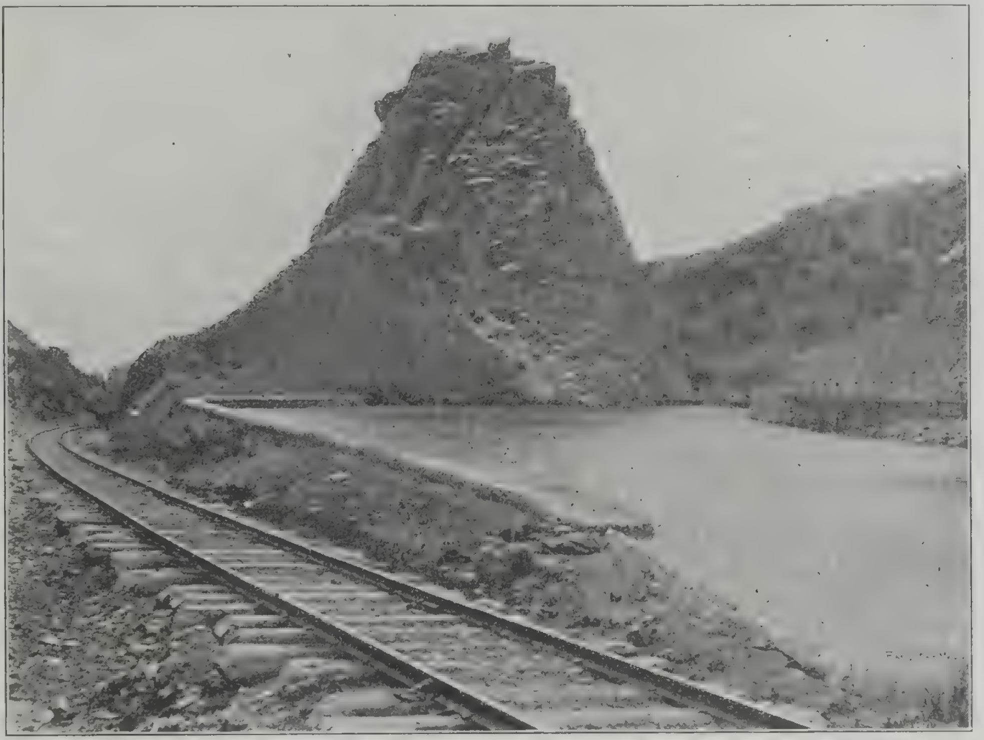

FIG. 2.—VIEW OF PARLEY'S CREEK HEAD-WORKS FROM UP-STREAM SIDE.

other pipe, for discharging surplus water into the city irrigation system, near by. The tank and valve chambers are enclosed within a neat and substantial brick house.

The 13th East St. reservoir is only partly completed. It has yet to be lined before being of any service, and it will then hold about 6,000,000 gallons. It is located about 1,000 ft. west of the relief tank and is about 130 ft. lower. The water from the 30-in. pipe from the tank discharges through an 18-in. pipe and a flume into a wooden tank set within the reservoir and with its overflow at the same elevation as the overflow of the brick tank for the low line supply in City Creek canyon. They thus do not interfere with one another by discharging into the same pipe system. The relief tank is at the same elevation as the tank house in City Creek canyon, where water is taken out for the 20th Ward, so water from these two tanks can be turned into the same system without interference.

A 20-in. main leads from the reservoir west on 1st South St., being soon reduced to 18 ins., and then to 16 ins. at 8th East St., and extending to West Temple St., or over two miles.

The water of Parley's Creek is often very muddy during fall and winter, after rain or cloud bursts, and always so in the spring. On this account it is regularly used only in the summer season, when it is more clear and when the other creeks cannot supply the demand.

Distribution System.

The greatest fault with the distribution system is the insufficient size of the mains and sub-mains. This was caused partly through ignorance of the city councils and partly because the system was built up piecemeal as the increased demand made necessary, not being planned broadly enough at the start.

On numerous streets the mains laid were only 3 and 4 ins., and from one of these as a trunk the laterals or branches would be laid. These were laid with dead ends, the system resembling a tree with projecting branches, only with the branches often larger than the parent trunk. There were 4 and 6-in. hydrants, and in one place a 6-in. hydrant was connected with a 2-in. main, the hydrant, of course, being of no use. These faults have been largely remedied during the last few years by putting in larger mains and by connecting the pipe so as to do away with dead ends as much as possible. In the 20th Ward system the mains are still mostly 3-in., and about 33,500 ft. here need to be replaced by 6-in pipe. The business part of town comes under the low line system, which supplies about two-thirds of all the water used. Following is a summary in round numbers of different sizes of pipe in the ground at this time:

Size, ins.	No. ft.	Size, ins.	No. ft.
30	110	10	3,500
24	2,620	8	33,000
20	2,400	6	341,000
18	3,700	4	138,000
16	9,100	3	61,000
14	11,900		
12	38,000	Total	644,330

or about 122 miles. Besides this there have been over 7,000 ft. of 1½ and 2-in. pipe discontinued or abandoned. There have been placed about 1,425 valves and nearly 900 hydrants. The hydrants used are the Howe, Galvin and Ludlow. The Howe is an old type of hydrant that was made in Salt Lake. Nearly all of this make have been remodeled so as to make them effective. Those of 4-in. size are single and of 6-in. are triple nozzle. The Ludlow hydrants are 6 and 4-in., and are nearly all triple nozzles. The gates or valves used are the Boston, Ludlow and Galvin. The service pipes are all of lead, and are mostly ½ in., with ⅝-in. and ¾-in. for the larger houses.

The static pressure on Main St., in the business center of town, is 100 to 110 lbs. per sq. in. With a heavy draft during the summer the pressure often reduces to 60 to 65 lbs., while 90 to 100 is the average. By turning water from the 20th Ward system into the low-line here, the pressure is increased by 50 lbs. An ample supply with a strong fire pressure is thus secured. The Emigration or City Creek high-line system would increase the pressure to 250 lbs., entirely beyond the strength of the down-town pipes to withstand.

About 5,000 acres is reached by the supply system, thus taking in not less than 80% of the inhabitants. During the summer, when there is a large amount of water used for lawn and street sprinkling, the consumption reaches over 12,000,000 gallons daily, or 250 gallons per capita. During the winter the consumption does not reach over 8,000,000 gallons, daily, and the water of Parley's Creek is not then used. A very large amount of the water of the three creeks named was formerly used for irrigation, both for public irrigation of shade trees in the city and by private parties. In order to secure a supply to meet the demand for this irrigation water the city has for several years brought water through a large canal from the Jordan River, near Utah Lake, which is the source of this river and is about 30 miles south of the city. This water is used to supply irrigators in exchange for their water rights on Parley's Creek, and for the city's own uses. The lake will in time probably be the key to the solution of the problem of an increased water supply for domestic purposes, as water from it will have to be exchanged with pure water from the other mountain streams, these already being appropriated by farmers and millers. The minimum flow from the three creeks used occurred in 1889, when it fell to 8,000,000 gallons. The flow has been much increased by development of springs and other underground sources since then.

Considering all the possibilities in the way of supply, Salt Lake City should never have any serious trouble in obtaining sufficient water, even with a population of 500,000 or more. The value of the present water supply system, as an asset to Salt Lake City, has been variously estimated at $1,000,000 to $3,000,000; $2,000,000 is probably a safe figure to put it at, and it is doubtful if it could be bought for this, even if the constitution of the state did not prohibit it, as the people are violently opposed to any private corporation ever obtaining control of it. The actual cost of the plant has been but a fraction of this, though large sums have been spent on it at one time and another; but the water-rights and privileges and the ownership of much of the land in the valleys of the creeks are of the highest value.

U. S. IMPORTS AND EXPORTS FOR 1893-1896.

U. S. imports and exports for 1893-96, inclusive, are reported upon, as follows, by the U. S. Department of Agriculture: During the ten years ending June 30, 1896, the United States exported domestic merchandise to the value of $8,207,292,566, and it re-exported articles of foreign origin to the amount of $149,785,038, making our total exports in that decade, $8,357,077,604. Our imports during the same period were valued at $7,656,127,784; and the total commerce of the United States, for the ten years 1887-1896, was thus $16,013,205,388, or a yearly average of more than $1,600,000,000. The total exports for 1896 show an increase of $75,068,773 over 1895, and the imports an increase of $47,754,709, or an increase in total commerce of $122,823,482 over 1895, or about 8%. The figures for the present fiscal year also show an upward tendency, though this is not quite so marked as was the gain in the last fiscal year.

The exports of domestic merchandise, grouped by sources of production, are given for the years 1892-1896, inclusive, together with percentages of each group, as follows:

Year.	Agriculture.	Manufactures.	Mining.	Forest.	Fisheries.	Miscellaneous.	Total for year.
1891	$642,751,344	$168,927,315	$22,054,970	$28,715,713	$6,208,577	$3,612,364	$872,270,283
Per cent.	73.69	19.37	2.53	3.29	0.71	0.41	
1892	799,328,232	158,510,937	20,692,885	27,957,423	5,403,587	3,838,947	1,015,732,011
Per cent.	78.69	15.61	2.04	2.75	0.53	0.38	
1893	615,382,986	158,023,118	20,020,026	28,127,113	5,541,378	3,936,164	831,030,785
Per cent.	74.05	19.02	2.41	3.38	0.67	0.47	
1894	628,363,038	183,728,808	20,449,508	28,000,629	4,261,020	4,400,944	869,204,937
Per cent.	72.28	21.14	2.35	3.22	0.49	0.52	
1895	553,210,026	183,595,743	18,509,814	28,576,235	5,328,807	4,171,974	793,392,599
Per cent.	69.73	23.14	2.33	3.61	0.67	0.52	
1896	569,841,714	228,480,893	20,412,153	33,718,204	6,585,814	4,152,709	863,200,487
Per cent.	66.02	26.47	2.37	3.91	0.76	0.47	

These figures show that in the fiscal year which ended last June, American farmers sold to foreign nations nearly $570,000,000 worth of their products, or about $17,000,000 more than in the preceding year. The sale of our manufactured products abroad grew faster still and their percentage of the total value of exports is now greater than for any year in the list; the gain of 1896 over 1895 being nearly $44,000,000.

The United Kingdom of Great Britain leads all other countries in exchanges with the United States. During the year ending June 30, 1896, we sold to the English speaking people of Europe merchandise valued at $406,000,000, or 46% of our total exports, and we bought from these people goods to the value of $170,000,000, or 22% of our total imports. Taking all parts of the British Empire in all continents, we find that they bought from us 58% of our last year's imports, aggregating in value $512,000,000. Next to England as purchasers come Germany, Canada, Italy, British Australia, British India, Japan, Russia and China, in about the order named. Our exports to Cuba have declined from $24,000,000 in 1893 to $7,500,000 in 1896, or only 31% of the value of the imports of 1893.

The value of imports for these six years, under the heads of dutiable and free, is thus given:

Year.	Dutiable.	Free.	Total Imports.	Total customs collected.	Per cent of free.
1891	$478,674,844	$366,241,352	$844,916,196	$219,522,205	43.3
1892	369,402,804	457,999,658	827,402.462	177,452,964	55.4
1893	421,856,711	444,544,211	866,400,922	203,355,017	51.3
1894	275,199,086	379,795,536	654,994,622	131,818.531	58.0
1895	368,736,170	363,233,795	731,969.965	152,158,617	49.6
1896	409,967,204	369,757,470	779,724,674	160,534,351	47.4

These figures show, for the year ending June 30, 1896, a gain of about $48,000,000 over 1895, and $125,000,000 over 1894, in the value of total imports. The articles that most contributed to the gain in imports last year were sugar, raw and manufactured wool, unmanufactured silk, wood and its manufactures, hides, tobacco, earthen, stone and chinaware, etc. We import most from England. As before stated we bought from her in 1896, goods to the value of $170,000,000; to this must be added the value of imports from her colonies, the aggregate being $259,000,000, or 33% of our total imports. After the United Kingdom comes Germany, Brazil, France, Canada, Cuba, Japan, China and British India, in the order named. Our imports from Cuba shrank from $79,000,000 in 1893 to $40,000,000 in 1896, and those from Mexico dropped in the same time from $34,000,000 to $17,000,000.

MOMENTUM FRICTION BRAKE FOR ELECTRIC CARS.

The design of an efficient and simple momentum brake for electric cars, such as has been used on cable cars, possesses several features of difficulty, the chief of which, perhaps, has been the limited axle space left available by the motor casings. Only about 5 or 6 ins. of the car axle is ordinarily left clear by the casing, and this affords a very contracted space in which to apply suitable mechanism, and practically excludes the screw on the axle, such as, for instance, the Johnson brake for cable cars has. In a recent invention by Mr. W. G. Price, of the Chicago City Ry. Co., of Chicago, Ill., however, the difficulty is overcome, if a successful operation of six months in actual service is a good criterion from which to draw conclusions. Through the courtesy of the inventor we are able to present illustrations of this brake, which is called a momentum friction brake.

Fig. 1 is a plan and section of a four-wheel electric car truck, showing the location of the friction mechanism and brake rigging. A friction disk A, with a suitable hub runs loose on a sleeve keyed to the car axle close to the wheel, which is of special construction, having a disk on the inside, against which the friction disk bears, as is clearly shown by Fig. 2. In the 2-in. annular recess in the friction disk hub are inserted the bifurcated ends of the levers, Fig. 3. These levers are located on the car as shown at B, Fig. 1. The operating rods C, Fig. 1, from the levers on the car platforms attach to the arm D, Fig. 1, shown in detail by Fig. 3—and this arm by its swing operates the screw, Fig. 3, so as to spread apart the lever ends resting in the annular recess, in a manner obvious from the drawing, Fig. 3. This spreading of the levers forces the friction disk, A, against the wheel, so that it turns with the wheel and winds up the chain E, Fig. 1, operating the wheel brakes, through the rigging, shown in Fig. 1.

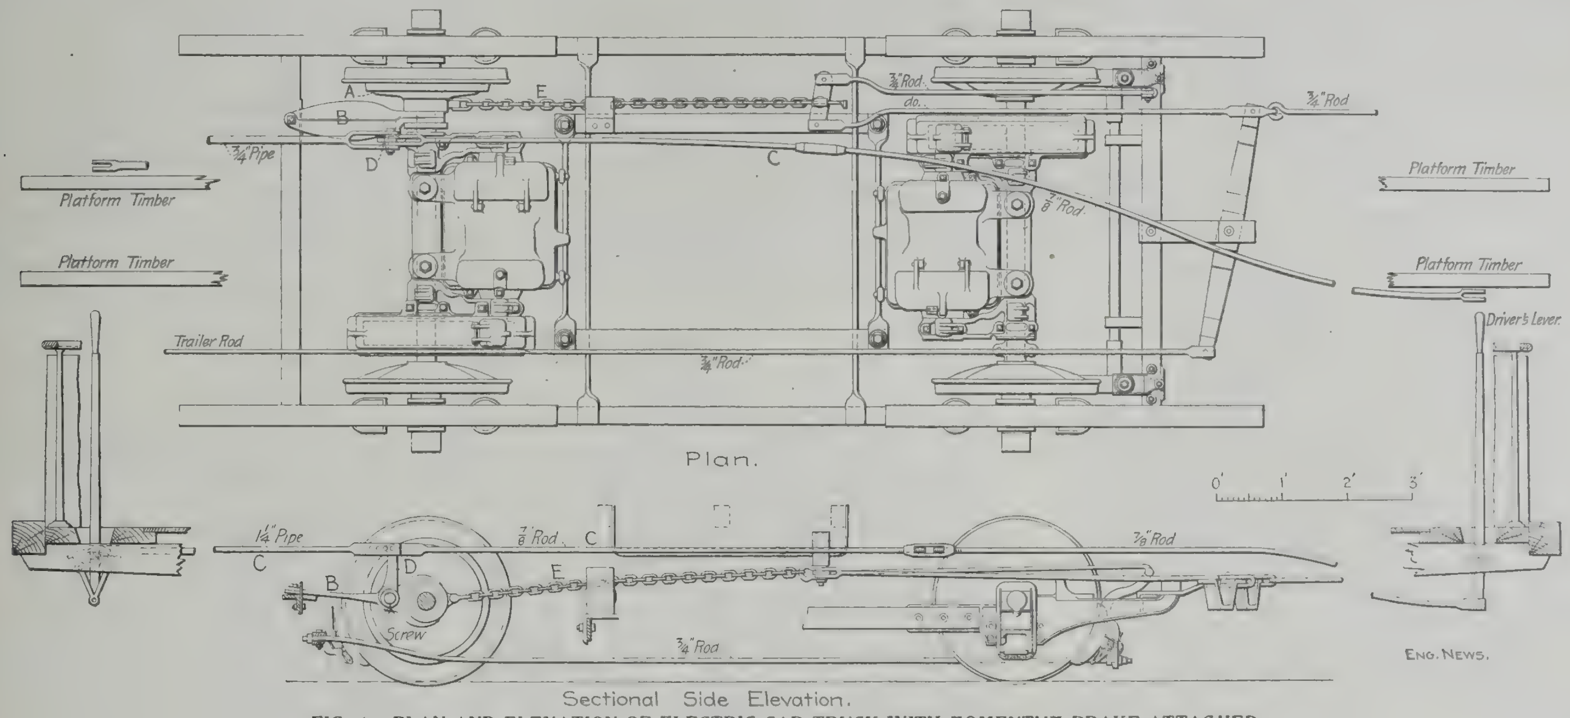

FIG. 1.—PLAN AND ELEVATION OF ELECTRIC CAR TRUCK WITH MOMENTUM BRAKE ATTACHED.
Used by Chicago City Ry. Co. Designed by Wm. G. Price.

When applying the brake the motorman pulls the lever a few inches toward him, and to release the brake he pushes it back again close to the dash of the car. When the brake shoes are properly adjusted a movement of the car of 18 ins. applies the brakes. It is adjusted by means of a ratchet on the head of the screw, and this adjustment can be done by the motorman in five minutes' time. The brake is oiled by means of an attached oil cup, which requires filling only once a week. Mr. Price states that the brake can be applied as quickly as an air brake, and works fully as smoothly by using the bend in the lever rods, as shown. Its release is instantaneous.

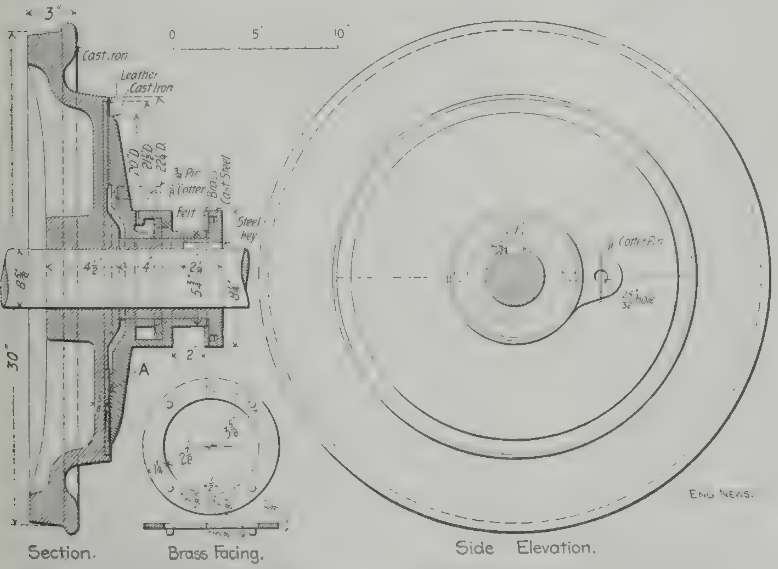

FIG. 2.—SECTIONS THROUGH CAR AXLE SHOWING FRICTION CLUTCH OF MOMENTUM BRAKE.

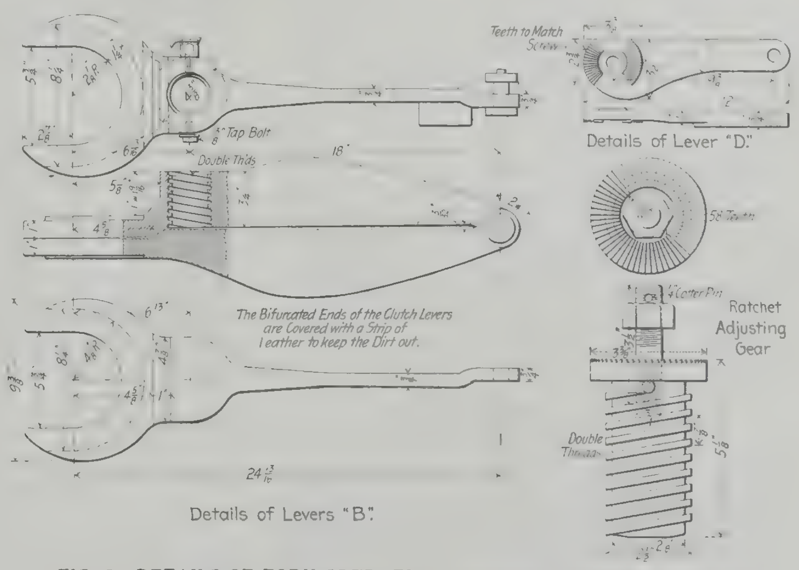

FIG. 3.—DETAILS OF FORK OPERATING CLUTCH OF MOMENTUM CAR BRAKE.

This brake has been in operation on several cars running on the Chicago City Ry. Co.'s lines for six months, and has proved so successful that it will be placed on many other cars during the winter. One of its principal advantages is the reduced physical labor required of the motorman in braking, and the reduced mental strain since he has much less fear of accidents. It is also expected to reduce the number of "slid-flat" wheels.

THE BATES THERMIC ENGINE CO.

Public announcement was made in the Philadelphia daily papers about Oct. 1, of the great success of a wonderful new engine, which, it was claimed, would save 80% of the fuel consumed by ordinary steam engines, and invitations were given to the public to see the engine in operation at No. 1040 Ridge Ave. The Bates Thermic Engine Co., 652 Philadelphia Bourse, at about the same time issued a pamphlet advertising the engine, and a circular "Prospectus," headed "A Revolution in Motive Power," "Consumption of Coal 80% less than with Steam Engines," etc. According to this prospectus the company is chartered under the laws of West Virginia; capital stock, $5,000,000; shares, 100,000 at $50 each, of which 15,000 shares are now offered for sale at $10 per share. The company owns the exclusive rights to manufacture, use and sell the Thermic engines in the State of Pennsylvania, in the State of Delaware, and in the State of New Jersey, south and including Trenton. The officers of the company are Russell Thayer, President; A. E. Kennelly, vice-president; Wm. J. Elliott, secretary and treasurer. The directors are James McManes, Edwin J. Houston, Allen B. Rorke, Henry Clay, David S. B. Chew and Geo. H. Holgate. Some of these names are well known to engineers. Mr. Thayer is a Member of the American Society of Civil Engineers and is Chief Engineer and Superintendent of Fairmount Park. Mr. A. E. Kennelly is an Associate Member of the American Institute of Electrical Engineers and one of the managers of that society. Prof. E. J. Houston is a Member and Past-President of the American Institute of Electrical Engineers, and is a scientist and an authority on electrical subjects whose fame is world-wide.

Certainly the fact that engineers of such eminence are the managing officers of a new engineering enterprise ought to be a good guarantee of its soundness from an engineering standpoint, and should therefore strongly recommend it to investors. We often hear of inventions which are to generate power with a fraction of the fuel used by the steam engine; but it is seldom that any of these new inventions are vouched for by such an array of names as that above noted.

With this in mind, we deemed it well worth while to undertake an investigation of the new motor, for which such large claims were made, and a member of the staff of this journal visited Philadelphia, examined the engine in operation and secured all the information available concerning the new motor and the company formed to exploit it.

According to the pamphlet issued by the company, the history of the motor is given as follows: M. Gardie, of Nantes, France, patented a gas engine in 1889, and assigned his patent to the "Societie Anonyme des Moteurs Thermiques Gardie." After M. Gardie's death, experiments were continued by the society for five years, under the direction of Maurice Lorois, who succeeded in perfecting the system, and patented the present engine in 1894. The Bates Thermic Engine Co., of Philadelphia, was organized, and purchased the exclusive rights under these patents for the states of Pennsylvania, Delaware and part of New Jersey, as above noted. It then made patterns from the original drawings furnished by the French company. The engine was then built by Mr. A. Falkenau, whose machine shop is at 11th St. and Ridge Ave., Philadelphia, in the basement of which the engine is now running.

We have secured from the patent office copies of the U. S. patents of M. Lorois, of which one is for a process of manufacturing gas, No. 529,453, and the other for a gas motor, No. 529,452, both dated Nov. 20, 1894. The latter patent gives a very complete description of the engine and its operation, from which we condense the following: Fig. 1 is a diagrammatic view of the engine with its appurtenances, and Fig. 2 is a front view, partly in section, of the engine.

An air pump or compressor P compresses atmospheric air to a pressure of 43 lbs. per sq. in. and upwards, into an air reservoir Z, where the water is separated from the compressed air. The compressed air passes from this reservoir through a pipe and branch pipes and into two heat interchangers or regenerators R R′, in which it is heated by the spent gases of combustion exhausted from the power cylinders C C of the engine. The heated compressed air passes from the interchanger R′ by a pipe x to the gas producer G, constructed as a cupola furnace. At the same time superheated steam is introduced to this producer as hereinafter explained, and commingling with the air flows through a mass of incandescent fuel in the producer, whereby is generated the combustible gas. This gas, being produced under the same pressure as that initially given by the air pump, passes out from the producer by a pipe and enters a dust separator N, which disengages any dust or ashes from the gas and then flows through the pipe Q′ to the inlet ports of the power cylinders C C. The compressed air which is heated in the interchanger R passes therefrom by a pipe which has branches leading to the air inlet ports of the power cylinders.

The operation of the engine is as follows: On the opening of the inlet valves the heated compressed air and hot compressed gas which until now have been separate, and which are both at the initial pressure given them by the pump P, flow in suitably regulated proportions into the cylinder, entering it at the commencement of the stroke of the piston and being ignited by contact with the walls of the cylinder and piston, which thus serve as the igniter. The gas and air being mixed in the proportion necessary to complete combustion, burn in the cylinder. The gases continue to enter while the piston moves through a portion of its stroke and up to the instant when the inlet valves are closed. Up to this time the pressure continues the same as the initial pressure given by the compressor, and which is maintained in the gas producer and all the apparatus. From this moment the expansion of the gases commences, and as the piston recedes the pressure falls, while in acting against the piston the gases develop mechanical energy, and in consequence undergo a considerable reduction in temperature. At the end of the working stroke of the piston the exhaust valve is opened, and during the return stroke the products of combustion are expelled from the cylinder and ultimately escape into the atmosphere. The pistons of the two cylinders work alternately, each developing power on its working stroke, and being driven by the other on its return stroke. The hot spent gases of combustion expelled from the respective cylinders are conducted through pipes to the two heat interchangers R and R′, through which the flow, giving up their heat to the compressed air which is flowing oppositely through these interchangers, and the spent gases being finally discharged through a pipe into the atmosphere, producing neither noise or smoke, and having given up nearly all of their heat. At the same time water is forced by a pump p, through a pipe t″, which divides into two branches, conducting the water into jackets h′ surrounding the lower portions of the power cylinders, from which jackets the water passes by pipes t‴ into jackets h surrounding the upper portions of the cylinders, these upper jackets constituting steam generators wherein by the heat disengaged in the cylinders the water first heated in the lower jackets is converted into steam, and the steam flows through a pipe s^2 to the gas producer, wherein the pipe is formed into a coil or superheater s exposed to the intense heat of the newly generated gas, whereby the steam is highly superheated, after which it is conducted through a passage s′ down through the heated brick work or lining of the producer, and commingled at the lower part thereof with the heated compressed air introduced through the pipe x.

The gas producer G is constructed to resist pressure. It has a strong outer casing or jacket of sheet steel, within which is built a fire-brick lining. It is provided with a feeding hopper on top having a tight closing lid and a delivery valve. By closing the valve and opening the lid, the hopper can be filled with fuel, whereupon by tightly closing the lid and opening the valve this fuel falls into the producer.

The operation of the gas producer under pressure in connection with the pre-heating of the air, and the superheating of the steam, enables a much higher temperature to be maintained in the gas producer than has ever been possible heretofore. The result is to furnish a gas having a high calorific power, and completely free from tar and ammonia.

A partial combustion occurs in the gas producer which is sufficient to maintain it at the high interior temperature required. The gas being free from all impurities which would necessitate the use of condensers and purifiers, permits complete suppression of such purifying apparatus with their attendant necessity of cooling the gas. The rate of production of the gas can be varied from time to time in accordance with the varying requirements of the engine, so as to allow of the complete suppression of a gasometer between the gas producer and the engine. As the fuel in the gas producer is consumed it settles to the bottom and the resulting ashes or slags may be removed from time to time through an orifice by opening a tightly closed lid or door.

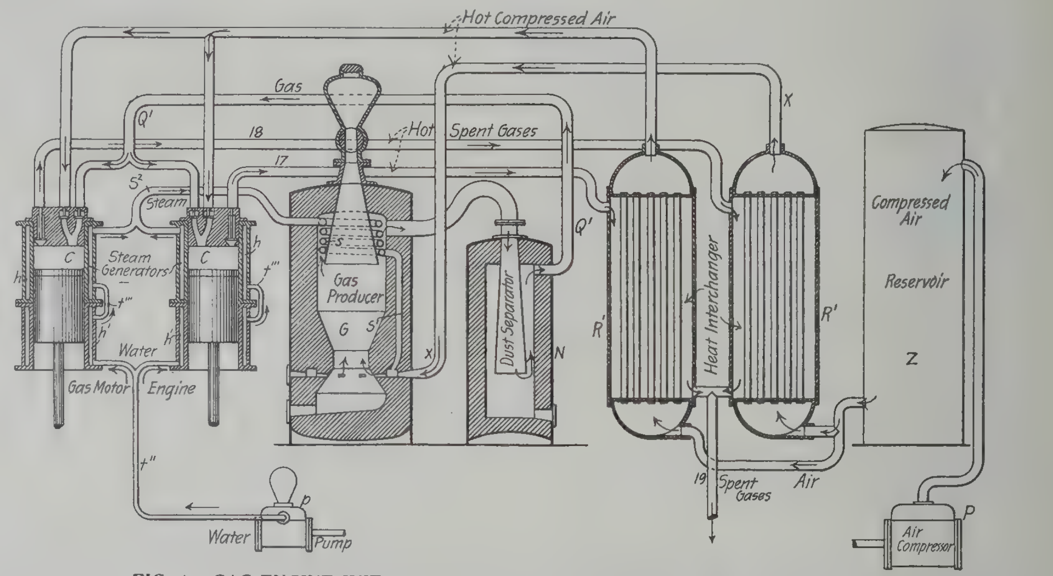

FIG. 1.—GAS ENGINE WITH GAS PRODUCER WORKING UNDER PRESSURE.
Patented by M. Lorois, Nov. 20, 1894.

The dust separator N has a strong outer shell which is protected by a refractory non-conducting lining as shown.

The heat interchangers RR′ are each constructed with an upright cylinder of sheet metal, having at top and bottom two cast domes, between which are extended numerous tubes fixed at their ends in two metallic tube sheets. The whole construction is surrounded by an independent cast jacket.

The two motor cylinders C are alike, each being single-acting. Each cylinder is divided into two parts, the upper or hotter section being made larger than the piston or plunger, while the lower or cooler section is made to fit with the piston. The upper section is provided with a non-conducting substance, and with a plate i of a suitable heat-retaining metal adapted to maintain a sufficiently high temperature for automatically igniting the gases. The piston is of considerable height, its lower part which never leaves the cooled lower section of the cylinder being provided with packing rings K. For lubricating the cylinder, oil is contained in a collar l, into which the lower flange of the piston dips. The lubrication of the piston is made possible since the temperature of the lower portion of the cylinder does not reach 60° C. The lower section of the cylinder is cooled by the circulation of cold water in the jacket h′.

The top of the piston P′ is also provided with a plate i′ of a suitable heat retaining metal insulated by asbestos. Nickel is a suitable metal for the plates i and i′. As the plates are always red hot, the combustible gas and heated air introduced through the gas and air inlet ports, mixing in the cylinder in contact with these plates, is ignited and burns without explosion while being introduced, remaining at the initial pressure of 3 kilos. per sq. cm. or upward (this pressure once determined upon remaining constant).

The diagrammatic view of Fig. 1 is a very fair representation of the system used in the engine as installed in Philadelphia. The arrangement of the parts, however, is somewhat different, thus the two heat interchangers are located so as to adjoin the two power cylinders, and the ground plan of the whole is arranged so that all the apparatus is contained inside of a floor area about 16 ft. square. The cylinders of the Philadelphia engine are each 15¾ ins. diameter and 15¾ ins. stroke.

The engine being constructed as above described, the next question likely to be asked is, what results have been obtained from it? To answer this we have recourse to the pamphlet issued by the company. It contains a report by Mr. Thomas Pray, Jr., who adds to his name the initials C. C. and M. E. These letters, we understand, do not mean that Mr. Pray is a graduate of any engineering school or a member of any society of engineers, as some readers may imagine, but they are simply an abbreviation of the words "Consulting, Constructing and Mechanical Engineer," which appear at the top of his report. Mr. Pray's report is a literary as well as an engineering curiosity, as will be seen by the extracts which we quote from it below. It is not remarkable for its brevity, covering some 28 duodecimo pages, and we have even had some difficulty in finding out from the report what economy the engine actually showed under his test. On this subject, in fact, Mr. Pray makes a charming variety of statements, some of which we quote "verbatim et literatim," as follows:

> P. 5. Your engine burns less than 1 lb. of coal per I. HP., and when delivering 100 HP. at its belt will consume less than 1.2 lbs. per HP. per hour from the data of present actual tests made.
>
> P. 9. Economy of fuel consumption for large marine engine.—This engine in large powers can undoubtedly produce its indicated HP. at less than 0.9 lb. of coal, including the power for air compressors, and the required auxiliary steam.
>
> P. 14. When the engine is in full motion doing 81.9 HP., not varying two revolutions per minute and the load running from the one just mentioned to 82.9, we have to put a hod of poor quality of PEA size coal into the gascogen once in 24 minutes.
>
> P. 19. The coal now in use is a "pea size anthracite," costing in the coal bin, $3.75 per ton, and from picking it contains 2 lbs. 5 oz. of slate in a hod of 28 lbs., or 8.3% of refuse before it goes into the gascogen for use, or we buy 91.69% of real coal, and 8.3% of waste, and from this coal the past week we find that with an indicated horsepower of slightly more than 82, that in regular operation it calls for .85367 lbs. of coal for 1 I. HP., one hour, not making any consideration of the loss of over 8% of the coal in worthless slate, but which is paid for and counted as used; if we figure the performance of the engine as we do that of the steam engine, by allowing the refuse of the coal, the result will be changed to in the last amount of .78319 lbs. of coal for 1 HP. for one hour.
>
> The amounts stated above are from the total load of the engine as it was running yesterday, September 4th, but as it is intended to not consider the air compressor as "power" and it is intended to consider the engine as indicating about 140 HP. in order to take off 100 HP. from a belt, I have estimated that "as intended" taking the actual load as above, and the results stated as actual, with a "commercial result" of taking the first actual amount of .85367 lbs. for one hour of 1 HP. and suppose your engine does its work only as efficiently as it has in the four days of this week, and your slate is as good as COAL, and 40 HP. is actually done in compressed air, and the coal is counted to do that 40 HP. but in your figuring you say the 40 HP. is not power, and call your load 100 HP. then your engine would use in one hour 119.52 lbs. of coal, which was actually 8.3104% slate, it would indicate 140 HP., but you don't credit it as power only for 100 HP., as all you get on a belt, and all this would cost you 119.52 lbs. coal.
>
> PERHAPS SOME OF YOUR BOARD KNOW OF STEAM ENGINES DOING THAT? I DON'T; and now as we are in a speculative mood we go one step farther, and take

> out the slate; and call the 40 HP., not commercial, actually indicate 140 HP., but only figure 100 as transmitted to your machinery, and we shall have for THAT train of conditions, the using up of 109.64 lbs. of coal each hour to furnish you "business men" with 100 HP. to run your looms, or spindles, electric cars, or any other purpose you may choose, and as you are figuring now, you get 100 HP., 109.64 lbs. of coal, with NO slate in it, and still get your air pumped for nothing with which to make gas.
>
> Now, in either case you will give me credit for not deducting anything for ashes, or for moisture in the coal, and the basis I have taken is that your engine has only 58% of its rated load, and you are almost at ONE pound of poor coal for 1 HP. one hour.

The above extracts give fair examples of Mr. Pray's lucid literary style, and from them we glean after considerable study that the engine has actually given one indicated horse-power for 1 lb. of coal, that it may be expected to give a brake horse-power for 1.2 lbs., and that it is believed it will show still better economy when built in larger sizes than 100 HP. An engineer reading these figures would naturally inquire, How much better is this result than the results obtained from other gas engines? Mr. Pray, C. C. and M. E., makes no attempt to answer this question in his report, but instead flourishes a comparison between the Lorois gas engine and the steam engine. The pamphlet issued by the Bates Thermic Engine Co. opens with an extract from a lecture delivered by Mr. Pray before the Franklin Institute in 1889, from which we quote as follows:

> In the ordinary form of steam engines the expenditure of 5 to 8 lbs. of coal per horse-power per hour is not considered excessive, and with the latest improved type of quadruple compound condensing stationary engines, the best results show that from 2 to 3 lbs. of coal are necessarily consumed in the production of a horse-power per hour.

With all due respect to Mr. Thos. Pray, Jr., C. C. and M. E., it must be said that a fuel consumption of 5 to 8 lbs. per horse-power hour in a steam engine is considered excessive, and that instead of a quadruple engine "necessarily" consuming 2 to 3 lbs., such engines have given on test a consumption of less than 1.4 lbs. But in any fair study of the possibilities of any new form of gas engine accomplishing a "revolution in motive power," its fuel consumption should be compared not with that of such a poor variety of steam engines that "a saving of 80% of fuel" can be shown by the comparison, but with the results which have already been obtained with other gas engines which have been on the market for years. In order to show what actual saving, if any, the Lorois engine, with its consumption of 1 lb. per 1 HP. hour and 1.2 lbs. per B. HP. hour, makes as compared with other gas engines, we quote the following from the 2d edition (1896) of Mr. Bryan Donkin's recent work on "Gas, Oil and Air Engines:"

> In the Otto-Crossley gas engine, using Dowson gas, the consumption of anthracite is from 1.0 to 1.4 lbs. per I. HP. per hour, or of coke 1.5 lbs. (Donkin, p. 91).
>
> In 1891 a test of an Atkinson gas engine at the Uxbridge Water Works, with Dowson gas, gave 21.95 I. HP., and the consumption of anthracite was 1.06 lbs. per I. HP. per hour (p. 106).
>
> In 1895 a 65-HP. Stockport gas engine, near Tonbridge, with Dowson gas gave a result of 0.93 lb. fuel per I. HP. hour or 1.6 lbs. per B. HP. hour. Another test on an engine driven by Dowson gas at Portadown gave 44.6 I. HP., the consumption of best Welsh anthracite being 0.91 lb. per I. HP. hour (p. 119).
>
> At Schwabing, near Munich, a 40 B. HP. Otto engine, worked with Dowson gas made from German anthracite gave a consumption of 1.54 lbs. per B. HP. hour (p. 120).
>
> One of the latest types of Tangye engine is a single cylinder engine of 24. ins. diam. and 30 ins. stroke, driven by Dowson gas, with a consumption of 0.8 lb. Welsh anthracite per I. HP. hour (p. 122).
>
> A simplex gas engine of 81 B. HP. tested at Aubervilliers, in France, in Nov., 1894, using the Lencauchez gas generator showed a consumption of 1.10 lbs. of Anzin coal per I. HP. hour, and 1.45 lbs. per B. HP. hour. Another simplex engine of 220 B. HP. at Pantin, France, tested in Feb., 1894, showed a consumption of 0.80 lb. Anzin coal per I. HP. hour and 1.02 lbs. per B. HP. hour (p. 483.)
>
> A Schleicher-Schumm Otto gas engine, tested by Prof. Spangler, of the University of Pennsylvania, in 1892, using the Taylor gas producer, gave 92.5 B. HP. with a coal consumption of 0.94 lb. per I. HP., and 1.30 lbs. per B. HP. hour. (Jour. Franklin Institute, May, 1893.)

It will be seen that the test last quoted was made in Philadelphia four years ago, on an engine built in Philadelphia, and it gave a result nearly the same as that now given by the Lorois engine: and yet the Otto engine has not yet proved itself a "revolution in motive power" to such an extent as to seriously interfere with the market for steam engines.

The Gardie engine (of which the Lorois engine is a later form) is referred to on p. 162 of Mr. Donkin's book as below; the Lorois engine does not appear to be mentioned:

> One of the latest developments in gas engines is the introduction of motors having gazogenes attached, in which generator or power gas is made per stroke and passes direct to the engine, without intermediate storage in a gas holder. Two forms of this apparatus have lately appeared in France, the Gardie and the Benier; the former seems to be still in the experimental stage. * * * *
>
> In the Benier engine the gas is produced automatically per stroke as required, by the suction of the motor piston; thus its quality is said to be always uniform, and being generated below atmospheric pressure, loss by leakage is avoided. As the gas is only at atmospheric pressure a pump is required to mix it with air and deliver it to the engine.

From an examination of Mr. Lorois's patent it appears that the essential difference between his and the Benier engine is the manufacture of gas in the Lorois system under high pressure, 43 lbs. per sq. in. or above. The only advantage which this method can have, apparently, is the superiority of the quality of the gas made under pressure, which is claimed by M. Lorois. The power to compress the gas and the air is exerted by a separate air compressor, while in gas engines using the Otto cycle the power is exerted in the cylinder of the engine itself during the "compression stroke." There does not seem to be any important difference as far as the power required for compression is concerned, whether it is exerted in the engine cylinder or in the compressor cylinder. The difference, if any, in the quality of the gas, in favor of the Lorois method does not give any direct advantage in fuel economy, its sole advantage consisting in the alleged freedom from tarry matters liable to deposit in the cylinder and valves of the engine, and the consequent suppression of the scrubbers and washers which are used in connection with the gas producers of ordinary gas engines. To offset this advantage the whole plant, including air receiver, heat interchangers, gas producer and dust catcher, together with the piping system, has to be built of sufficient strength to resist with abundant safety the pressure which exists throughout the plant, 70 lbs. in the engine at Philadelphia. This necessitates a somewhat expensive construction.

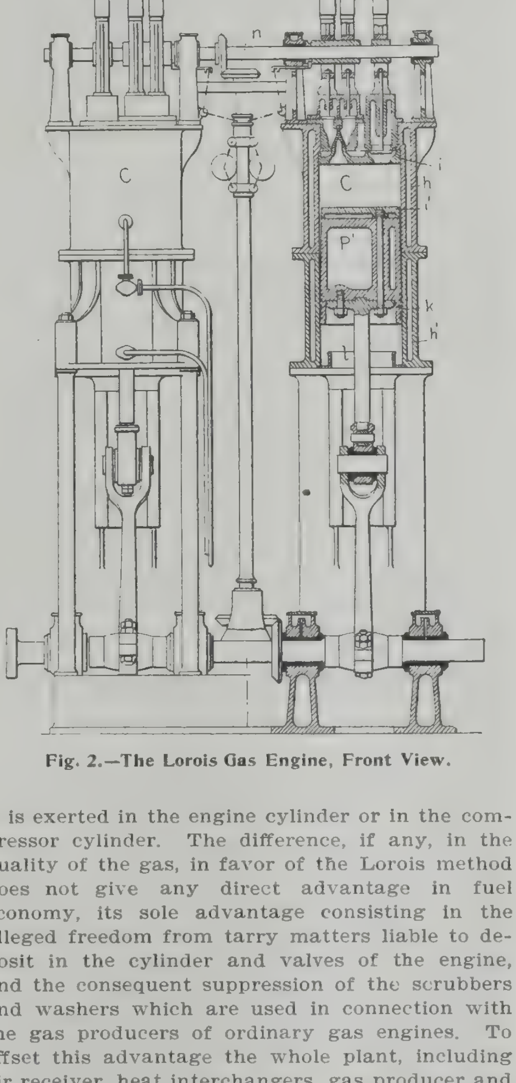

Fig. 2.—The Lorois Gas Engine, Front View.

Mr. Pray discusses a number of other features of the engine, besides its fuel consumption. His following remarks concerning the operation are interesting:

> To start the engine a small auxiliary steam boiler is required, for a short time, and so far as possible for me to say, an 8-HP. boiler would handle this 100-HP. engine, and furnish the steam required until the engine had its own steam. it is also necessary to have a dynamo of about ⅜-HP. output to run the firing wire until the plates are hot, and the dynamo in use, is used for from 55 to 70 minutes, according to pressure and load, when it is "cut out of circuit" and is of no further use until the engine is cold; this is also true of the auxiliary air compressor, a small one outside of the engine is needed, for charging to start with, but when running, if any accident to belts or machinery occurs necessitating a stop, there is no difficulty with ordinary care, in holding the pressure for some hours, and starting on as easily and with the same certainty as with half a dozen steam boilers with "steam up," for, if the air connections are tight, they will hold for ten hours or more, pressure sufficient to go on and re-heat the whole, which requires ten to twelve minutes (at proper pressure), and in that time the whole load can be taken on and run with no waiting for "steam" or pressure.
>
> When running, the proportions of air to the gascogen, and of steam, can be easily and certainly known, with the same care used or needed in operating a steam plant, but with no such waiting for "steam to get up" the fire requires constant feeding, not continual, but at stated intervals, and if it is allowed to get low and is still in the possibilities to keep at speed, you can add one or two hods (we feed 28 lbs. at a time in coal hod)—and in three minutes you can get on full, then add at stated intervals as already stated (28 lbs. in 24 minutes keeps nearly a 100-HP. going), with a surplus at the end of the day. And in its full load and speed, it will compare with the best built steam engines very favorably, as to care and the amount of work to be done on it, but it is not a machine that will run without care and attention, or by a careless man in its charge, nor will it do to put ignorant men, or cheap ones who know nothing and care less, into the care or charge of such a high speed sensitive machine, using such heat, but with the men who delight in fine running machines, ease, certainty, and fullest control, this motor will be more than welcome; it cannot be blown up, unless by criminal intention, and I do not know now how it would be possible to do that; there is not a trace of smell from the gas, and a person visiting the machine cannot tell whether it is run by one or the other force, from any smell which is perceptible in or about the room where it is.
>
> When the gas does escape, it has a smell once experienced, not forgotten, hence it is not insidious, and is so apparent that if it was poisonous it could not endanger human life, but when smelled it gives in a few moments a feeling as though a hearty dinner had been eaten, and in about six hours a most peculiar headache, in front, above and through the temples, and this is about twelve hours in leaving, after which no "after effects" are perceptible.

Mr. Pray concludes his report as follows:

> YOUR ENGINE IS THE NEAREST APPROACH TO THE DREAM OF SCIENTIFIC MEN OF MANY YEARS, BY WHICH THE ENERGY IN COAL WAS TO BE DIRECTLY APPLIED TO THE PRODUCTION OF POWER. I do not imagine that your board appreciate the value of what you have in your hands, in a strict business way. The engine has been sensitive to changes, and has in every point responded to adjustment, and shown its capacity for hard work, its beautiful regulation, and its great efficiency, ease of management, and if it is put into proper hands for future development, and conducted on lines intended, it will be the fault of whoever has it in charge, it is NOT one of the most successful business ventures attempted in the line of "prime movers."
>
> I have become more and more pleased with the splendid ability of the inventor, and the persistent patience of his French nature in putting his ideas into iron and steel for the benefit of the human race.

Our own opinion of the engine, after examining the engine itself and carefully reading M. Lorois's patents and Mr. Pray's report, is that it is a gas engine which may some day, at considerable expense, be developed into an engine which will be a commercial rival of the Otto and the numerous other gas engines that are now on the market. Its method of saving heat by means of the regenerators or heat interchangers, is not new, and they may be applied to engines of the Otto type whenever the saving of heat made by them is found to justify their cost. Whether the advantage of the manufacture of a gas which requires no washing or scrubbing, which is claimed for the Lorois system is sufficient to compensate for the increased cost of apparatus, which the production of gas under pressure makes necessary, is a question which can only be answered after long experience in practical work.

The machine embodies some interesting departures from ordinary gas engine practice, such as the igniting of the charge by the hot interior of the cylinder; but the figures of Mr. Pray's test do not show that the net results of these departures is to make the machine generate power with any less fuel consumption than is attained by other gas engines now on the market.

Perhaps when the apparatus has been further developed and perfected, better results will be shown; but after a careful perusal of Mr. Pray's report we are constrained to believe that he has said everything favorable that can be said concerning the machine in its present condition.

In view of all these facts we can see no shadow of justification for the capitalization at $5,000,000 of a company which owns not even the patents on this motor, but merely the rights for two states and part of another under patents of unknown value and has, so far as we can learn from its own published statements, no other property whatever. The capitalization of the enterprise and the valuation at which it is offering its shares appear to us to be about as exaggerated as are the rhetorical flights of Mr. Pray's report. Some other aspects of the subject we have discussed in our editorial columns.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; *6 months,* $2.50; *2 months,* $1.00; *Single copies,* 15 *cents. To all other countries in the Postal Union, add* $2.08 *per annum (4 cents per number) to above prices for postage. No club rates allowed. Mailing addresses may be changed at will by sending both old and new address. We shall be obliged if subscribers who fail to receive their papers promptly will notify us without delay. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number* 326 *means that subscription is paid to the 32d week (that is the issue of Aug 6) of the year* 1896; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: 20 *cents per line agate measure. Want notices, special rates, see page 22. Rates for standing advertisements sent on request. Changes to standing advertisements must be in hand on Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon*

According to items from the daily press now in circulation the timber dry-docks lately built at our various government navy yards are being seriously damaged by marine worms. The Bureau of Yards and Docks of the U. S. Navy Department is also credited with being inclined to favor the construction of stone docks hereafter, as being in the end more durable and economical notwithstanding their first heavy cost. This news would be important, if true; but inquiry made of the proper sources of information leads to a very different conclusion. Timber dry-docks have now been in use in the United States for over 30 years, and somewhat longer than that in England. Official inspection of the older docks in this country shows that the timber in the interior is unaffected by the teredo-navalis, as this part of the structure is empty much of the time, and it is impossible for the worm to do any considerable damage in the short working time at its disposal. But the teredo does attack the dock entrance, and the outer parts of the caisson abutments, and when made of timber these must be renewed from time to time. It is for this reason that the Puget Sound dry-dock, the latest one completed by the U. S. government, is provided with a concrete abutment lined with cut masonry, and the approach wing walls are also of concrete faced with stone. As to the general durability of timber dry-docks it is found that the timbers in the oldest one in this country are practically intact and exhibit no decay except upon a very thin outer shell. The timbers in the upper part of the dock proper, above mid-tide mark, do deteriorate in time, but these can be readily renewed at a comparatively small cost. As this part of the dock could easily be constructed of concrete, by cutting off the piles at low tide mark and capping them, it seems strange that this is not done in our government docks, especially at Puget Sound, where concrete was extensively used for purposes of protection. It is clearly demonstrated by expert examination and by actual experience with these docks for more than 30 years, that timber dry-docks are not only comparatively very cheap to construct and generally durable, but that with a little additional expense they can be protected efficiently against their worst enemy, the teredo-navalis.

When it comes to a question of comparative cost, between stone and timber docks, the advantage is decidedly with the latter. The Mare Island stone dry-dock, at San Francisco, is 513 ft. long and 79 feet wide and is said to have cost about $4,000,000 to build. The Puget Sound timber dry-dock is 650 ft. long by 97 ft. wide and cost $607,951, or less than one-sixth of the cost of the stone dock. But the timber dock is not only vastly cheaper, but is vastly more convenient for working upon the hull of a ship. There is really no comparison between the modern wide-flaring, well-lighted and roomy timber dock and the steep side walls of the average stone dock. The Mare Island dock, in this respect, compares more nearly with the timber dock, as it has a much flatter slope and is wider in proportion than any of its stone predecessors; but to build a stone dock on the generous proportions of the later timber docks would make the cost prohibitory. If the interest on the cost of the Mare Island dock is taken at 4 per cent. it will be found that this accumulated interest would build a timber dock of the Puget Sound type about every five years, even assuming that the cost of the latter was increased by a sum sufficient to replace with concrete the whole upper part of that dock now exposed to gradual decay. And this estimate does not take into consideration the fact that the timber dock was completed in 43½ months as compared with the ten or eleven years consumed in the construction of the Mare Island stone dry-dock. In view of these considerations it is not at all probable that the government engineers propose to return to the old stone type of dry-dock construction.

◆

The review of the prospectus of the Lorois gas engine, on another page in this issue, will prove interesting reading to those who are watching the progress of the gas engine in its rivalry with the steam engine for use in electric lighting and power plants. The fact that gas engines are capable of furnishing power at a fuel cost of but little over 1 lb. per brake horse-power hour, while few steam engines, even of the most expensive types, have shown a better record than 1½ lbs., should induce engineers who have anything to do with the installation of new electric plants to give the gas engine careful attention. The probability of the gas engine supplanting the steam engine to any serious extent, however, seems at present remote. Fuel economy is not the only thing to be considered in the selection of motive power, and the disadvantages of gas engines in other respects, such as high first cost, difficulty of keeping in order, expense of operating gas producers etc., which have hitherto kept the gas engine from being a dangerous rival of the steam engine, are likely for some years to come to delay its progress.

In this connection a recent experience with gas engines at Aurora, Ill., is of interest. The gas company desiring to supply electricity as well as gas light to its customers, bought a number of dynamos and had them set up in the engineroom of the Aurora Street Ry. Co., which company ran them by belt from its steam engines. The gas company, thinking it could run its dynamos more cheaply by gas engines than by rented steam power, purchased under guarantee a number of gas engines and removed the dynamos from the railway company's power-house to its own. After about two weeks' trial, the gas engines were condemned, and returned to their builder, the dynamos were set up again in the street railway power-house, and the gas company is now planning to buy boilers and engines and run its dynamos by steam in its own gas works.

◆

The common method of power transmission on board naval vessels is by steam pipes, extending from the main boilers to the various engines, and the great variety of machinery which is necessary on a modern battleship makes a great amount of steam piping necessary. This piping is objectionable for many reasons. It is bulky and takes up valuable space, when protected as it must be with non-conducting covering. The covering is subject to more or less deterioration with the vibration of the ship and the machinery. The heat from the pipes is objectionable in every closed space. The necessity of providing for the exhaust and of keeping the pipes drained of condensation is a constant source of trouble. But more than all else is the danger which exists in every such steam pipe in time of action. The cutting of any one of them by a projectile means the escape of high-pressure steam, involving in a horrible death every one within its reach.

At the International Congress of Naval Engineers at Chicago in 1893, Mr. George W. Dickie, of the Union Iron Works, of San Francisco, advocated a system of hydraulic power transmission for use on ship-board, with large pressure pumps in the engine room and Pelton wheels, hydraulic rams, etc., to perform the work of dynamo driving, hoisting, etc. The system certainly possesses many advantages over the steam distribution system, especially with respect to its freedom from danger; but the equipment which has been installed on the U. S. monitor "Terror" seems to even surpass it in efficiency. On this vessel, as described in a news note in this issue, compressed air is used for performing all the various mechanical operations on board, from moving the rudder to hoisting ammunition. That this is far superior to a system of steam pipe distribution or to the scattering of donkey boilers over various parts of the vessel, will be apparent. The only system that promises to be able to at all compete with it is electrical power distribution. It would appear that compressed air would be superior to this in simplicity for direct hoisting, while where a rotary motion is wanted the electric motor would have the advantage.

That one or the other of these systems, or perhaps both combined, are bound to displace the dangerous steam pipes wherever shot and shell can come, seems certain. If two vessels were to engage in such a naval duel as that of the "Kearsarge" and the "Alabama" for example, one equipped with steam pipes and the other with electric or compresed air transmission, it would take a great deal of superiority in armor and armament in the former to make its chances of success in the contest equal.

◆

In these days of improvements, real and alleged, those in charge of both public and private undertakings have a host of devices presented to them for examination. The advocates of these devices do not always have an opportunity to set forth the reasons for their adoption, and even when they do, the claims urged are often speedily driven from the minds of those to whom they are presented by a multiplicity of cares. If a fairly good article of a certain class is in service there is a natural tendency to continue it in use, without giving much attention to alleged improvements, urged in the ordinary manner. Numerous changes in standards are often disadvantageous, although in some lines it matters little whether a new article is like those of the same class previously used, the main object being to have the best, regardless of previous custom. In the course of a few years, often in a very few, important improvements are sure to be made in almost every line. On this account a general survey of the field is desirable now and then. Such a course gives ample opportunity for comparing various devices and settling upon the best in a truly critical manner, instead of relying upon impressions gained from time to time in a few hasty moments, and perhaps due quite as much to the suavity of a skillful agent as the merits of the device. A careful examination of one class of appliances is about to be made by the New York Department of Public Works, as noted in our news columns last week. Valves, hydrants and accessories are to be considered with care, first through the literature put forth by manufacturers and next through an exhibition, to be held Nov. 10, at the Corporation Yards, 437 East 24th St., which yards are in charge of Mr. A. G. Gear. All communications on the subject should be addressed to Gen. Chas. H. T. Collis, Commissioner of Public Works, 150 Nassau St., New York city.

◆

The separation by means of magnetic machines of materials which have hitherto been considered non-magnetic, which is described in the paper of Messrs. Wilkens and Nitze, elsewhere in this issue, is the latest novelty in metallurgical processes, and one that may some day prove to be of great importance to owners of deposits of low grade hematite iron ores. There are vast bodies of such ores in certain districts of this country which are now entirely valueless by reason of the availability of low-priced better ores in their vicinity. In other places high grade and low grade ores are found in the same mine, and the latter are now left in the ground or thrown away on the waste dump. If they can be concentrated by the new magnetic machines at reasonable cost, a notable benefit to the iron trade will result, in the securing to it a new and large supply of cheap ores.

ENGINEERS AND SPECULATIVE ENTERPRISES.

In the "Code of Ethics," which has been adopted by the Canadian Society of Civil Engineers and was printed in our issue of Feb. 13, 1896, occurs the following:

> The Civil Engineer should avoid connecting himself with schemes or projects of a merely speculative character, always bearing in mind that his professional reputation will be to a great extent judged by the inherent merits and commercial value of the undertakings with which his name may come to be associated.

If this code of ethics be considered as nothing more than a statement of general principles, which one may accept or reject as he pleases, it will yet be agreed, we believe, that no more sound and wholesome advice could be given to an engineer than is conveyed in the above.

The commonest question which is ever asked concerning an engineer is, "What work has he been connected with?" People in general judge an engineer not by his stores of knowledge, or his executive ability; not even by his professional work, so much as by the character and the success of the enterprises with which his name comes to be associated. We are speaking now, of course, not of subordinate positions, but of the engineers in responsible charge of work. No one will deny that this standard is often an unjust one. Because the financial management of an enterprise causes its ruin is really no reason why injury should be done to the reputation of the engineer, who very likely did hard and faithful work all through. But be the standard just or unjust, it is the standard which people in general accept, and the fact is one which every engineer will do well to bear in mind.

It will, of course, be understood that we are not speaking now of the reverses which may come to any buisness enterprise, though these to some extent fall under the same rule, but rather of the enterprises "of a speculative character," as the code of ethics above quoted describes them. Concerning new enterprises the code says:

> The Civil Engineer whose advice is sought in respect to the usefulness, practicability and cost of a work should, before expressing his opinion, obtain reliable information on all points involved in the matter submitted to his judgment, including the probable paying capacity of the contemplated undertaking.

No one, we presume, will question that the term "Civil Engineer" in the above quotation should be given its broadest meaning, and that the rule of conduct is applicable equally to engineers in all branches of the profession. Let us express the same thing in somewhat different words: The engineer sells advice. He is subject then to the same rules that govern all trade. If he sells good, safe and sound advice, the demand for his services will continue. But if he gives bad advice in return for his fee, either through ignorance or because he wishes to say what will please his client, he will soon find that no one wants to buy advice of that sort. Even the clients who want an engineer who will twist his report to further their ends without regard to the truth, will pass him by because they know that his word carries no weight with the investing public.

These things are not fancy or mere theory by any means. We have in mind, as we write, concrete instances. In one case an engineer's name was used in connection with a concern against which a "fraud order" has been issued recently by the Post Office Department through the efforts of this journal. It need hardly be said that nothing can ever efface the injury done to that engineer's professional reputation by that connection. Another engineer has become noted for his connection with schemes of a highly speculative character. His reports upon them, designed to attract investors, are marvels of ingenuity; but he has become so well known in this field that the mere fact of his connection with an enterprise is sufficient to make one look upon it with suspicion.

If the engineer whose ignorance or dishonesty leads him into such a course injured only himself and those who are foolish enough to rely on his opinions, his misdeeds would be of comparatively little interest to the profession at large. The punishment would fall where it was deserved. But this unfortunately is not the case. The engineer who gives bad advice or whose work fails always brings discredit upon the profession, just as surely as the engineer who succeeds in a great work raises the profession in the public estimation. And the injury done to the profession by an unworthy member is tenfold greater where it is the honesty and not merely the engineering ability that is at fault.

But it will be said that it is unfair to hold the profession at large responsible for the acts of individual members. Any one, no matter what his qualifications or lack of qualifications, may call himself an engineer and may sell engineering advice—if he can find purchasers for it. This is, of course, true; and yet, we believe that in this matter, the public is not quite so ignorant as is sometimes thought. People do understand, we believe, the difference between the engineer of character, reputation and high standing in the profession, and the ignorant and incompetent man, whose claim to the title of engineer rests on no substantial basis. It is clear then that the injury done to the profession when its members of high reputation commit unworthy acts is by far greater than can result from the acts of those hangers-on of the profession whom the public generally estimates at their real worth.

And if this is true, it follows at once that the members of the great engineering societies, and especially such members as have attained professional eminence owe to their fellow members and to the profession at large an avoidance of anything which may result in discredit to the profession. Perhaps there is no temptation which meets such engineers oftener than proposals of connections with "speculative" enterprises. We are far from saying that the engineer should on principle refuse all such offers. Every new enterprise must have something of a speculative character at the start. But it is clearly the duty of the engineer to scrutinize every such enterprise with the greatest care before associating himself with it in any capacity where the public may be led to place confidence in it by reason of his connection. The engineer who is asked as an expert to report on such an enterprise or who is offered an executive position in it must accept the responsibility that necessarily accompanies such a position. People who invest their money will do so on the strength of his opinions, and if the investment proves a loss, his reputation, and to a certain extent the reputation of the profession will suffer. The only safe rule to follow for an engineer in such a position is—to tell the truth and the whole truth. Ascertain the facts which count against the success of such an enterprise as carefully as you do those which make its prospects promising, and report them as faithfully to those who contemplate investment. This may seem Quixotic to some, but the engineer who pursues any other course is gambling with his own reputation.

What would be thought of a lawyer who in submitting a report upon the title to a piece of property included all the favorable documents and omitted any which threw a cloud upon it? Why should not the engineer be held to an equal responsibility? Is it not clear that he must be so held, if engineering is to be the honorable profession that it deserves to be?

It may be argued that investors could not be secured for enterprises if they were not painted in glowing colors. We do not believe this. Nearly every one who invests money in new enterprises would far prefer an honest, unbiased report of the prospects of failure and of success from an expert. It is not too much to say that the scheme which cannot attract capital upon a fair and impartial showing of its points of merit and of risk, ought not to succeed.

If there be any of our readers who hold that the position we have urged is too advanced for engineers, at the present day, we invite them to consider for a moment the result of taking an opposite position. Suppose, for the sake of argument, that an engineer is justified in presenting in his report only facts favorable to an enterprise. Suppose, we say that he may occupy an executive position in such an enterprise, and permit the distribution of misleading statements respecting its engineering features. If such a condition of affairs were to obtain, it is clear that engineers' reports would be worthless as a guide to investors; and we may be sure it would not take the public long to find out this fact. Would a banker be responsible if he occupied an executive position in a concern and permitted it to publish misleading statements as to its financial condition? Would an attorney be responsible, if, as one of the officers of a company, he misled investors as to its condition with respect to pending litigation? We realize well that in any such case the public would be prompt to hold such men to a due responsibility for their acts; and so in like manner does it hold the engineer responsible.

LETTERS TO THE EDITOR.

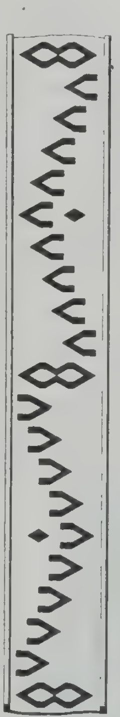
Paving Along Street Railway Tracks.

Sir: Referring to the article in the last issue of the Engineering News, entitled "Paving Along Street Railway Tracks," and the criticism of Mr. H. P. Jones, concerning the plan for paving along the street railway tracks in this village, contained therein, I wish to say that the plan covered only the paving proper and had nothing to do with the substructure of the track, the local authorities having no control over that portion of the work. Though strongly urged to put concrete under the ties, the local street railway managers refused to do so, stating that as they have to maintain the track in good order, they should have the right to choose the method of constructing it; and the village authorities are powerless in the matter as the laws relating to villages give them no control over the substructure of the tracks. I am aware that a durable or permanent street railway track can be best obtained by using a concrete foundation under the ties, but in the case noted such a roadbed cannot be secured.

Respectfully yours,
Wm. B. Landreth.

Cortland, N. Y., Oct. 17, 1896.

A New Stadia Rod Graduation.



Sir: I enclose a design for the graduation of a stadia rod which is simple and easily read. The groups of divisions for each 100 ft. are alternated or staggered, and thus at long distances the hundreds of feet are more easily counted than if they were placed centrally on the rod. Another advantage is that no black division extends entirely across the rod, so that wherever the wires may cut, the white spaces which they cross are greater than the black.

Some engineers might prefer to have distinguishing numbers for each 100-ft. interval, but I have never experienced the need of such distinctions even when working in heavily wooded territory. Mr. Kenneth Allen has advocated the use of small mirrors, inserted at certain points on the rod, as an aid in avoiding mistakes at long ranges.

To prevent the graduations on the rod from being scratched or defaced, it is advisable to have narrow projecting strips down each side, and in order to protect the rod during transportation, the upper portion should fold forward upon the lower, so that the graduations are face to face.

Yours truly,
T. J. McMinn, M. Am. Soc. C. E.
277 Pearl St., New York city, Oct. 1, 1896.

THE PROPOSED CANADIAN FAST TRANSATLANTIC STEAMER SERVICE.

Deeper canals, "fitted to handle the Western as well as the Canadian trade," are advocated by the Premier of the Dominion of Canada, and in this connection a fast Atlantic service between Canada and Great Britain is also proposed. But Mr. Sandford Fleming, M. Am. Soc. C. E., one of the most prominent engineers of Canada, has lately issued a pamphlet pointing out the difficulties of maintaining the 20-knot service on the St. Lawrence part of the route, which has been suggested. Speaking of the Belle Isle entrance he says that all winds from the southward bring up fogs, requiring the greatest caution in navigation; and for 200 miles east and 100 miles west of Belle Isle, icebergs may be encountered. Within and sometimes even beyond these limits, the track of steamers is rarely free from icebergs, and fogs are nearly always present. Mr. Fleming concludes that any attempt to establish on this route a line of steamers intended to rival in speed those running from New York, would end in disappointment; and to secure an all-the-year-round line, Halifax, in Nova Scotia, and Loch Ryan, in Scotland, present the shortest available route for fast steamers. He says that this route is 300 miles shorter than to a Milford Haven terminus; 81 miles less than to Holyhead; 90 miles less than to Southampton, and 125 miles less than to Liverpool. But Mr. Fleming believed that steamships of moderate speed could be usefully employed on the St. Lawrence route in the transport of staple products and ordinary cargo; and that steamers suitable for this trade could, at the close of navigation, in the St. Lawrence, find an open harbor at St. John, N. B., the nearest suitable Canadian seaport for the cities on the great river.

In the same connection, Mr. John Torrance, of the "Dominion Line" of steamers, at the late launch of the steamer "Canada," said that this steamer was built for a 16-knot speed, and with this speed she had a cargo capacity of nearly 7,000 tons. But if this same steamer were equipped for an 18-knot speed her cargo would be reduced to 3,000 tons; and at 20-knots, to 1,000 tons. As a consequence, he said, if a fast service is desired it must be practically devoted to passengers alone; and the freight and passenger service must be separate and distinct. He thought such a fast service would not pay commercially.

Mr. T. G. Shaughnessy, Vice-President of the Canadian Pacific Railway, answered Mr. Torrance by saying that his experience was that if business was to be secured proper facilities must be provided, and that there was a happy medium between the extremes of high speed and great freight capacity. He illustrated his remarks by saying that with old and slow boats on the China, Japan and Vancouver route, the proprietors lost $150,000 in 1888, though they received from the C. P. R. 75% on all through rates. They rarely secured more than 30 first-class passengers on a voyage, and this number was reduced to 12 or 13 in the winter months. The Canadian Pacific Ry. Co. then built ships of 16½ knots speed, with accommodation for 175 first-cabin and over 1,000 steerage passengers, and with a freight capacity of about 4,500 tons. These ships he said have been a financial success almost from the start, and they carry from 160 to 170 first-cabin passengers in summer, and rarely less than 40 in the winter.

COUPLINGS FOR MAKING LEAD AND IRON PIPE JOINTS WITHOUT SOLDER.

The accompanying illustrations show a method of connecting lead to lead, or lead to iron pipes, without the use of solder. Brass couplings are used for this purpose, and the ends of the lead pipe are swedged up to fit against rubber washers resting on corrugated cone-shaped surfaces.

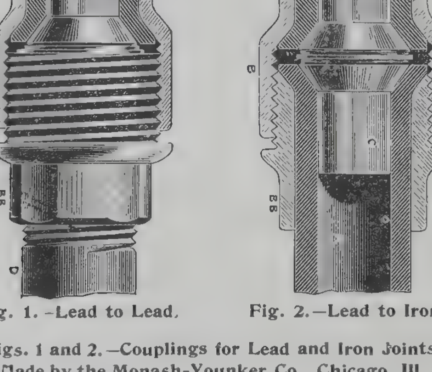


Fig. 1.—Lead to Lead. Fig. 2.—Lead to Iron.

Figs. 1 and 2.—Couplings for Lead and Iron Joints. Made by the Monash-Younker Co., Chicago, Ill.

Fig. 1 shows the lead to lead connection. To make this joint the brass parts, B and BB, are swedged onto the ends of the pipe to be jointed, making use of a swedging tool and clamp furnished for the purpose. The tubular double cone, CC, with the rubber washer pressed against each cone, is then put in place and the couplings are screwed up tight. Fig. 2 shows a lead to iron joint and needs no explanation. A variety of other joints, tees and connections can be made in the same general way.

The couplers and fittings are made by the Monash-Younker Co., successors to the Van Auken Steam Specialty Co., 201 South Canal St., Chicago. The company states that they have been in use for the past three years, and presents testimonials to the effect that they have given satisfaction in water-back connections and other places where both hot and cold water are used. It is claimed that the rubber washer, as here used, coming in contact with lead and brass, only, is not subjected to the disintegrating effect observed in iron unions, where much oxidation is going on.

As compared with the lead wiped joint it is obvious that any mechanic with ordinary tools can make these connections with ease, and it is claimed that their first cost is less and their safety and durability is greater than that of the wiped joint.

THE MAGNETIC SEPARATION OF NON-MAGNETIC MATERIAL.*

By H. A. J. Wilkens and H. B. C. Nitze, South Bethlehem, Pa.

The paradoxical title above used requires some explanation. The term "non-magnetic material" is applied to such substances as have heretofore been considered non-magnetic in the arts, more especially in the practice of ore-concentration.

Scientifically, it has been shown by Faraday, Plucker, Wiedemann and other physicists that magnetism is an inherent property common to all substances, solid, liquid and gaseous, i. e., all substances are either attracted or repelled by the poles of a magnet, although in the great majority of cases the manifestation of this force is so feeble as to be measured only by the most delicately arranged physical apparatus. The substances attracted are known as paramagnetic, and those repelled, constituting by far the greater class, as diamagnetic.

The diamagnetics show but a slight deviation in intensity as compared with air, which is the neutral substance. Bismuth is the most diamagnetic body known, and its diamagnetic permeability, expressed in figures, is stated to be 0.99982, taking air as unity. The paramagnetics, on the other hand, show a wide variation in intensity or permeability to magnetic forces.

There exists, however, a distinct and wide gap between such as are highly magnetic and such as are only feebly so, and accordingly two classes might be made, namely, such as can be and such as cannot be lifted by the common hand magnet or equivalent power. To the first class belong the metals iron, nickel and cobalt, and the minerals magnetite and pyrrhotite, and these are the only substances that are generally recognized as magnetic; while all other paramagnetics, comprising the second class possessing comparatively infinitesimal magnetic susceptibility, are regarded in the arts as practically non-magnetic. The abrupt gap between these two classes is not occupied by substances of intermediate and graduated magnetic susceptibility. It is with this second class of paramagnetic substances that we are concerned.

Faraday's list, published in 1846, includes a large number of metals, chemical salts and organic substances. It will suffice here to give the list of metals: Paramagnetic: Iron, nickel, cobalt, manganese, chromium, cerium, titanium, palladium, platinum, osmium. Diamagnetic: Bismuth, antimony, zinc, tin, cadmium, sodium, mercury, lead, silver, copper, gold, arsenic, uranium,* rhodium, iridium, tungsten.

Various attempts have been made by physical investigators in Europe, with more or less success and reliabilty of results, to determine the specific magnetic permeability of substances. To give at least some idea of the great gap existing between the commonly known magnetic and some of the other paramagnetic bodies, the following results obtained by Delesse may be cited: Taking the magnetic attractibility of steel at 100,000, he found that of magnetite to be as high as 65,000, of siderite only 120, of hematite 93 to 43 and of limonite 72 to 43.

Practical engineers and inventors have either taken for granted that the magnetic susceptibility of substances was constant, and about what was indicated by the ordinary hand magnet, or, if they were acquainted with the universal magnetic permeability of substances, they have felt that the attainment of sufficiently high power to affect the extremely low susceptibility of the paramagnetics, other than iron, nickel, cobalt, magnetite and pyrrhotite, was impracticable within the bounds of practical economy. At all events, they have been discouraged from making any attempt to design electro-magnets capable of such peculiarly concentrated and condensed a field as to attract these substances.

Even in the present case useful results were achieved only after making many experiments and actual trials, carried on in the beginning, without any knowledge of the previous theoretical investigations.

A large number of machines have been invented and perfected for concentrating the so-called magnetic minerals, that is, magnetite and pyrrhotite, chiefly the former. When it became desirable to separate other ferruginous minerals, such as hematite, limonite, siderite, etc., which were in the generally accepted sense, non-magnetic, methods for converting them into artificial magnetite were resorted to. This was done either by an oxidizing or a reducing-roasting in or without the presence of carbon-contact.

On the same general principle, Mr. G. G. Convers, designed in 1892 a process for the separation of the franklinite-ore of the Franklin mines, New Jersey. This ore is a crystalline granular aggregate of franklinite, willemite and calcite, with smaller amounts of zincite, garnet, fowlerite, tephroite, etc. It was the object to obtain the willemite and zincite as free as possible from franklinite (the principal iron and manganese-bearing mineral), thus rendering the franklinite magnetic, so that it could be separated on Wenstrom magnetic drums. This process gave good results; but the cost of roasting and the uncertainty of a uniform magnetic product led to further experimenting, and finally the method, a direct magnetic concentration of these ores, without previous roasting, was evolved by Mr. J. P. Wetherill, manager of the Lehigh Zinc and Iron Co., South Bethlehem, Pa.

Mr. Wetherill found that not only the franklinite, but also the garnet, fowlerite, tephroite and similar deleterious iron and manganese-bearing minerals could be thus eliminated.

These surprising and important results were attained by utilizing a peculiarly high magnetic power, applied in machines especially adapted for the purpose, and sufficient to act upon the comparatively almost infinitesimal magnetic permeability of these minerals, instead of attempting (as had heretofore been done) to raise this low permeability to a point known in practice as "magnetic," that is, capable of attraction by a common hand-magnet or the electro-magnets heretofore employed.

Further investigations showed that a large number of ferruginous and manganiferous minerals, such as hematite, limonite, siderite, garnet, pyrolusite, etc., besides many chemical salts of iron, manganese and chromium were affected by this extraordinary magnetic power, and were thus adaptable to this method of concentration.

Letters-patent were granted to Mr. Wetherill for his method of direct magnetic separation of paramagnetic substances of low permeability from mixtures containing the same, as well as for the machines employed to obtain this result; and these patents are now owned by the Wetherill Concentrating Co., located at South Bethlehem, Pa.*

The machines for making these separations are of two types. In the first the magnetic particles are lifted away from the original mixture. The machine consists of two magnetic cores and bobbins and four pole-pieces, which are adjustable, so that they may be moved nearer or farther apart as desired.

About each pole-piece revolves a belt.

The ore is fed from a hopper by means of a feed roller upon a belt which carries it in a thin layer, say ⅛ to 3-16-in. thick, in close proximity to the space between the poles, and the magnetic particles are withdrawn and lifted up into the highly intensified field existing at this point. They are removed by a horizontal belt and carried into a receptacle.

The non-magnetic tails fall from the belt into another receptacle.

The intensity of the magnetic attraction can be accurately adjusted by changing the distance of the feed-belt from the pole-points; or, by changing the distance between the pole-pieces, or, finally, by changing the amperage of the current.

So far machines have been used with a capacity of from ¾ to 3 tons per hour, depending upon the number of pole-pieces used, the speed of the belts and the nature and size of the material operated on. By widening the pole-pieces and the feed-belts, the capacity can be raised; but this may ultimately reach a point where it will be more advantageous to multiply the number of machines instead of further increasing their size.

The amount of amperage necessary for producing the extremely high field is comparatively small. This is due to the large-sized and correctly proportioned cores, yokes and pole-pieces employed, and the almost perfect condensation at the pole-points of the vast number of magnetic lines generated in them.

For the separation of the Franklin minerals, where the magnetic heads produced consist of franklinite, tephroite, rhodonite, garnet, etc., from 3 to 8 amperes, with from 16 to 30 volts, are necessary. In the concentration of the Clinton red fossil-ore from 4 to 8 amperes were used. For limonite and pyrolusite a somewhat higher amperage is employed, from 10 to 15 giving a good separation.

---

*Abstract of a paper presented at the Pittsburgh meeting of the American Institute of Mining Engineers.

*According to later observations of M. Verdet, uranium is paramagnetic.

*U. S. patents Nos. 555,792 (dated March 3, 1896), and 555,794 (dated March 3, 1896).

The ability to adjust delicately the magnetic intensity of these machines permits, in many cases, the practical isolation from one ore of several products showing a slight difference of magnetic permeability. For instance, in the concentration of monazite sand the pure monazite can be separated from garnet and rutile at one operation, and the latter, by a slight change in the intensity of the current, can again be separated from each other.

Aside from the separation of several minerals from one ore, the discriminating power can be utilized for the separation of a desired quantity or quality of heads, where the magnetic mineral varies in itself in permeability. For example, in the concentration of the Clinton fossil-ores, the magnetic permeability of the hematite particles increases apparently with their percentage of iron, and either a small amount of high-grade heads can be produced with a low amperage, or a large amount of low-grade heads with a higher one. From a commercial standpoint, the exact quantity or quality which it would be advisable to produce would depend upon the increase in value of the concentrates per unit.

The machines described are adapted to dry concentration. Their arrangement for wet concentration would necessitate but a slight change in some of the mechanical features.

It is difficult as yet to judge of the full extent of the field to which this method of concentration is applicable. Its original application to the franklinite ores has been mentioned above. It should supplant those operations already enumerated, in which a magnetizing roasting has heretofore been found necessary before magnetic concentration, not only on account of the additional cost which the latter entails, but also because better results may be expected from the direct treatment of the raw material. Magnetizing-roasting is attended, in most cases, with considerable difficulties, such as the sintering and slagging of the ore, imperfect magnetization, etc., which not only decrease the quantity, but may also impair the quality, of the resulting concentrates. Such difficulties were encountered in the magnetization of the red fossil-ore of the Birmingham district and in the roasting of siderite-blende ores in several European localities.

Perhaps its widest application will be in the field of concentrating iron-ores, red and brown hematites and carbonates. It is estimated that over 90% of the material charged into the blast-furnaces in this country is of these classes, and that in European countries the proportion is even larger. These ores will practically be placed on the same level with magnetite, so far as the ability to concentrate them magnetically in the raw state is concerned.

Of importance to the iron and steel industry will be the concentration of manganese-ores, with which other methods of concentration, such as jigging, have always experienced difficulty and waste.

There are no doubt many other special cases in which this process of direct magnetic concentration may become applicable.

Among the materials, besides those mentioned above, which have been treated successfully are:

1. A mixture of apatite and rutile, occurring in a deposit near Charlottesville, Va.
2. Monazite-sands from North and South Carolina.
3. Garnetiferous rocks and schists, from which it was desired to extract the pure garnet.
4. Corundum ores, from which garnet and other deleterious ferrugunious minerals were to be removed.
5. Ores containing siderite as a deleterious ingredient, as in cryolite, for instance.

In certain metallurgical operations this method of magnetic concentration may form an intermediate stage, as, for instance, in the separation of pyrite from blende, after the mixture has received a dead roast to prepare the blende for the retorts.

Its application has not been exploited as yet in the chemical and other industrial arts.

Franklinite-Ores.—The process has been in operation on a large experimental scale at the works of the Lehigh Zinc and Iron Co., South Bethlehem, Pa., for the separation of the franklinite-ores. Some 15,000 tons of material have been treated here, and, on the basis of the experience thus gained, a large and comprehensive plant has been designed and erected at the mines of the Sterling Iron and Zinc Co., Franklin, N. J. This plant, having a capacity of 400 tons of raw ore per day, is about ready to go into operation. The ore, as it comes from the mine, is dried, crushed to 10-mesh size by means of Blake crushers and rolls, and sized. The franklinite, tephroite, rhodonite, garnet, etc., are removed on the Wetherill machines, leaving, as non-magnetic tails, a mixture of willemite, zincite and calcite, from which the latter is subsequently separated by jigging. The operation of the process on this material is highly successful, as is shown by the analyses at the bottom of the preceding column.

	Per cent.			
	Wt.	ZnO.	Fe.	Mn.
Run-of-mine ore	100	31.09	20.34	9.34
Franklinite separated	56	24.38	35.50	13.62
Willemite and zincite separated	28	60.00	1.50	6.10*
Calcite separated	16	4.00	....	....

*This manganese is to a great extent chemically contained in the willemite and zincite.

Clinton Fossil-Ores.—Of more general interest, on account of the greater application of the process and the large extent of the field, are perhaps the results obtained on the red fossil hematite-ores of the Birmingham district in Alabama.

The richer, soft ores of this district, such as are used in the furnaces, average from 45 to 48% in iron, and from 30 to 24% in insoluble matter. Such ores occur, however, only in few localities, which are limited in extent, and are now almost exhausted. By far the greater portion of the leached ore-beds consists of material running from 35 to 45% in iron and from 45 to 30% in insoluble matter.

This latter class of ore cannot be used in the furnaces to advantage, and is therefore practically worthless, unless the percentage of iron be raised by concentration, and at the same time the insoluble matter be proportionately decreased.

The tests on these ores were made under the auspices of the Tennessee Coal, Iron & Railroad Co., and were in direct charge of Dr. William B. Phillips, the consulting chemist of the company, who, for the past three years, has made a specialty of the problems involved in the concentration of the Birmingham ores.

Various working-tests were made on material from a great number of localities, and the results were verified by some 500 analyses made in the laboratory of the company.

Concentration-tests on this material by the Wetherill process gave the following results (calculated on a basis of 100 tons of raw ore):

	Iron. %	Insoluble. %
Original ore	48.03	25.20
	Iron. %	Insoluble. %
57 tons of heads, containing	57.10	13.10
28 tons of middlings containing	46.20	25.40
15 tons of tails, containing	10.00	70.80

It was further found that about 20% in weight of this raw ore could be brought up to: iron, 59.15%; insoluble, 10.45%.

At the prices offered for concentrates by the T. C. I. & R. R. Co., it would be perfectly feasible to purchase this grade of raw ore at the market-price, and make the concentrates at a profit. As, however, the ore of this quality is almost exhausted, the question of concentrating it on a large scale will hardly arise.

The above results compare most favorably with those previously obtained by the magnetizing-roasting process, particularly in the proportional amount of heads that were produced and the comparatively small percentage of iron carried in the tails.

The tests by direct concentration on the lower-grade ores showed a proportionately greater increase in the percentage of iron than those on the higher-grade material. The quality of the heads was, however, not as good, which shows that the hematite matrix in the low-grade ores carries a larger percentage of inherent insoluble matter than that of the richer ores.

Among others, the following results were obtained (calculated on the basis of 100 tons of raw ore):

	Iron. %	Insoluble. %
Original ore	41.58	37.51
	Iron. %	Insoluble. %
69 tons of heads, containing	52.00	23.00
31 tons of tails, containing	18.40	70.00

About 25% in weight of this original ore was raised to: iron, 56.40%; insoluble, 17%.

Tests were also made on the so-called "hard ore," which represents that portion of the ore-bed from which the lime has not been leached. The raw ore of this character, as used at the furnaces, averages: iron, 35.50%; insoluble, 17.50%; lime, 16%. From this were obtained from 50 to 60% in weight of heads, containing: iron, 48%; insoluble, 10.50%; lime, 10%.

The cost of mining this hard ore, on account of its being underground, is far in excess of that of the soft ore. And, therefore, although the use of such concentrates as were produced would be of great advantage in the furnace, the cost of mining 2 tons of raw ore would be too great to permit the use of 1 ton of concentrates obtained therefrom at a profit under present circumstances.

The above tests must be considered to a certain extent preliminary. There is no doubt that a wider experience with this material, and, as a rule, a somewhat finer crushing and more judicious sizing, will give still better results. Experiments have gone far enough, however, to prove that this process of direct magnetic concentration is not only technically the most feasible, but also commercially the most economical one.*

Brown Hematite-Ores.—To show the application of the process to brown hematite-ores, the following results, from experiments made at the testing-plant of the Wetherill Concentrating Co., South Bethlehem, Pa., may be of interest:

Brown Hematite from Iron Gate, Va., Allegheny Iron Co.

	Percentage by weight.	SiO_2. Per cent.	Fe. Per cent.
Original ore	100	31,29	42.08
Concentrates	63.4	11.24	51.04
Tails	36.6	66.00	31.74

Brown Hematite (Washer Tailings), Barren Springs, Va.

	Percentage by weight.	SiO_2. Per cent.	Fe. Per cent.
Original ore	100	29.93	32.03
Concentrates	30	7.43	53.14
Tails	70	39.58	22.98

Jigged Zinc-Ore (Consisting of Limonite and Calamine),
Wythe Lead & Zinc Co., Austinville, Va.

	Percentage by weight.	Fe. Per cent.	Zn. Per cent.
Original ore	100	18.60	29.57
Concentrates	33	49.45	5.58
Tails	67	3.41	41.40

In the application of this process, limitations will be encountered similar to those common to other methods of concentration. The constituents of the material to be concentrated must exist in a visible mechanical mixture, so that, after crushing, each constituent may be present in separate and distinct particles. As already stated, the Wetherill machines have successfully handled material up to ½-in. in diameter, and a coarser crushing than this is seldom advisable in concentration. As a rule, finer crushing is necessary on account of the structural condition of the raw material, as in the case in the Clinton fossil ores.

The antipathy against the use of fine ores in the blast-furnace has been greatly overcome by the successful utilization of the Mesabi fine ores in the Pittsburgh district, where 33% of material, running less than 8-mesh in size, constitutes the regular furnace-charge, and as high as 60% has been used without serious difficulty. Briquetting may, in some cases, be resorted to, especially where a self-fluxing and partially self-reducing briquette can be made, and where these advantages counterbalance the additional cost of manufacture.

When the difference between the magnetic permeability of the constituents is marked, a preliminary sizing of the material is unnecessary; but this must be resorted to, and the number of sizes be proportionately increased, as the magnetic difference becomes less. The process resembles in this respect an air or water-separation. In rare instances this difference may be practically nil, and a separation may become impossible. Such was found to be the case in the attempted separation of chromite and serpentine in a certain chrome-ore, these two ingredients showing practically the same magnetic properties.

Experience has shown that the actual cost of magnetic concentration, under usual conditions, will not exceed 5 cts. per ton of raw ore. The cost of preparing the ore for the machines by drying, crushing and sizing will depend to a great extent upon the character of the ore, locality of the deposit and other conditions, and will not differ from the corresponding cost under any other method of concentration.

SUSPENDED ARCH-CENTERS AT THE PORT OF BORDEAUX.

In building the new quays at the port of Bordeaux, France, the bad character of the soil and the unstable condition of the older works founded upon piles, at that place, made it necessary that some general plan be adopted that would reduce to the lowest degree the effect of the outward thrust of the filling material. With this end in view the engineers concluded to employ masonry arches, placed at right angles to the pier-line, and to support these arches by piers founded by the use of compressed air. The reasons for the employment of this system and a full illustrated description of the construction of these quays will be found in the "Annales des Ponts et Chaussees," for June, 1896, in a lengthy and interesting paper written by Mr. A. Pasqueau, Chief Engineer. One of the most novel features of construction was the use of suspended centers for the masonry arches connecting the piers, and these may be described as follows:

The foundation soil was made up of strata of mud, from 16 to 20 ft. deep, muddy sand and gravel, from 7 to 20 ft. deep, and a compact bed of yellow marl, or clay, lying from 50 to 66 ft. below datum; and upon this latter formation the piers were founded. This quay is 4,959 ft. long and required the sinking of 93 metallic, rectangular caissons or pier-foundations, by the employment of compressed air. The datum line used was 21.55 ft. below the highest known tide, and the height of the front edge of the quay was fixed at this highest tide mark. The normal rise of the tide is 18.04 ft. The face-width of the piers was fixed at 4 m., or 13.12 ft., from the springing line of the arches to 23 ft. below datum, and 5.4 m., or 17.71 ft. wide from that point to the foundation. The general length of these piers was 10 m., or 32.80 ft., with a face batter of 1 in 10 from the top to a point 23 ft. below datum. At this latter point a horizontal step increased the bottom length to 34.44 ft. Out of 93 piers, 9 were doubled in face dimensions, or made 8 m. wide at the spring, to support heavy cranes, etc.

---

*It is regretted that business negotiations and commercial calculations are not far enough advanced to permit figures of costs and value of the concentrates to be published at the present time.

The springing line of the arches was fixed at 1.50 m., or 4.92 ft. above datum, and the normal arch span was 12 m., or 39.36 ft., with a rise of 2 m., or 6.56 ft. The width of the arch was 10 m., or 32.80 ft. Upon the completion of the arches the openings were closed by a filling of broken stone, having side slopes of 45°, and with the front-toe of the filling terminating on a line with the face of the caissons at a general depth of 23 ft. below datum. The top of this rock embankment extends up to the crown of the arches and sand was used as a back filling. The arches themselves, the face wall above them, and the front faces of the piers, to a point 23 ft. below datum, are built of cut stone.

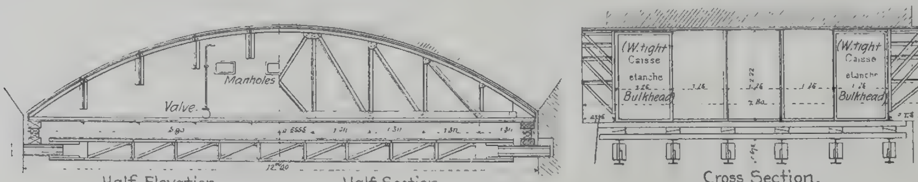
Fig. 2.—Details of Suspended Centering

The springing line of the arches was 2 ft. above the level of mean low water, or 4.9 ft. above datum, and it might have been possible to have used centering of the ordinary type; but such a center would have been very difficult to place and to strike, owing to the slight height available. In this emergency, the contractors, Messrs. Zschokke and Terrier, devised the system of suspended centers here described and illustrated.

The elevation and photographic view show the design adopted for this purpose. The contractors at first used two steel, trussed ribs, spaced 8.53 ft. apart, to support a center 16.4 ft. wide, and built the arch, which was 32.8 ft. deep, in two sections. But they later employed three ribs and built the whole arch at one operation. As shown in the elevation, these trussed ribs rested upon iron plates fixed upon the piers at an elevation of 3 m., or 9.84 ft. above datum, and, by long rods arranged normally to the intrados of the masonry arch, these trusses supported a series of metal panels, 2.88 ft. wide, forming the center desired. The stone arches were built upon this center in the ordinary manner, by leaving holes for the passage of the supporting rods. After a sufficient time had elapsed the centers were readily struck by loosening the nuts at the top of these rods and the centers were then lowered onto boats and transferred to adjoining piers by utilizing the rise and fall of the tide.



Half Elevation. Half Section. Cross Section.

FIG. 3.—FLOATING CENTERS FOR ARCHES AT THE BORDEAUX HARBOR.

Mr. Hersent, who had a later contract on the same work, preferred to use a floating center for his arches; but for those of slight span and rise he also employed the suspended centers, and he recommends them for emergencies of this character. The Hersent floating center was composed of six metal trussed ribs following the curve of the intrados of the arch and the line of the chord of the arch. The two outer trusses at each end were enclosed in plates in such a manner as to make tight boxes provided with manholes, air-pipes, valves, etc., and the upper part of this center was covered with wood for the support of the arch voussoirs. Iron-trussed beams were put in place, below the spring of the arch and between the piers, to support this floating center with its wedges, etc., as shown in Fig. 3.

The placing in position of this centering was simple. The center was floated by emptying the two tight boxes, at the ends, and was guided between the piers at high-tide; it was then settled down upon the cross beams, put in place at low tide, by introducing water into the end boxes. The water was left to circulate freely between the four middle ribs of the center. Upon the completion of the arch the wedges were struck in the ordinary manner; the end boxes were again emptied and the center withdrawn and floated to the next pier. It should be remarked that where these floating centers were employed the springing line of the arches was 8.20 ft. above datum, owing to a change in the type of the piers. The weight of one of these floating centers was about 39,600 lbs. and its cost was estimated at $1,200, not including the beams below the springing line; it drew 2.16 ft. of water with the end boxes empty The cost of handling this center for one arch was about $25, or about 20 cts. per cubic yard of arch masonry.

THE THIRD RAIL ELECTRIC SYSTEM ON THE NEW YORK, NEW HAVEN & HARTFORD R. R.

During the past summer the New York, New Haven & Hartford R. R. Co. installed the third-rail electric system on 3½ miles of the South Shore branch of the Plymouth division. This is the first surface railway that has ever operated its cars by a conductor laid upon the ground. A three months' trial has proved the success of the system for ordinary railway traffic at high speed. That part of the line where the third rail is laid is a continuation of the track on which the trolley is used. The trolley line is about seven miles long from Nantasket Beach to Nantasket Junction. At the end of this line the trolley slips from the end of the overhead wire, is pulled down and fastened and contact is made with the third rail. A knife switch under the hood of the car being closed, the current from the third rail is thrown into the motors and the operation of the train continues without interruption. The current for the third rail is brought from the power-house over two insulated feeders of copper cable laid along the tops of the poles which carry the overhead wires of the trolley division. At Nantasket Junction the feeders are dropped to the ground, and each is connected to its own third rail.

The third rail is of peculiar shape (Fig. 2), the end view resembling a flattened A; this form is used because it is cheaper than standard sections. It is laid in the middle of each track. Each section of third rail is 30 ft. long, and weighs 93 lbs. per yard. It is supported by three ash blocks to each section, the blocks being let into the ties. Before use these blocks were boiled in vacuum pans with a tar compound, and the cells thus filled with insulating and preservative material. At each rail-joint are two heavy copper bonds.

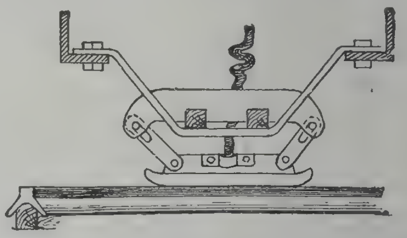

Fig. 1.—Side View of Sliding Shoe, Third Rail System; New York, New Haven & Hartford R. R.

The current is taken from the third rail by two sliding shoes (Figs. 1, 2, and 3) hung loosely from the car, one suspended between the axles of each truck by two slotted links which allow it to slide easily on the top of the third rail. The current is brought to the motors through the controllers and circuit breakers, and returns to the track rails by the wheels. The distance between the two shoes is 33 ft. No third rail is laid at the crossings, the circuit continuing between the broken ends by means of lead covered underground cables. At crossings less than 30 ft. wide, one of the shoes remains in contact, at wider ones the impetus of the moving car brings the shoes into contact again before the car can come to rest. The widest crossing which is run over in this way is 1,200 ft. Each shoe is a cast-iron plate 12 ins. long and 5 ins. wide, and weighs about 20 lbs. It is connected to the motor by a flexible cable. No difficulty has been experienced by the heating of the shoe from the friction, which is due probably in part to the air rushing past it, keeping it cool.

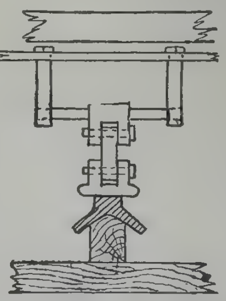

Fig. 2.—End View of Sliding Shoe, and Section of Third Rail; New York, New Haven & Hartford R. R.

The air for the brakes is supplied by an electrically driven air compressor automatically controlled by the air pressure itself. The apparatus consists of a double vertical air pump (Fig. 4) with single-acting cylinders, $5\frac{3}{4} \times 7$-in. stroke, directly connected to a series motor, the lower field of which is extended to form the base of the pump. The capacity of the pump is $52\frac{1}{2}$ cu. ft. of free air per minute, working against 90 lbs. pressure per sq. in. At this pressure the speed is 250 revolutions at 600 volts.

The air compressor is piped directly to the main reservoir, and is controlled automatically by a pneumatic governor consisting of a cylinder containing a piston working against a spring. The action of this automatic control is as follows: The pipe running from the main reservoir enters the cylinder below the piston. As the pressure rises the piston is forced upward against the spring. The other end of the piston rod carries the contacts through which the pump-motor circuit is made and broken. Any arcs that may be made when the contact is broken are blown out in a magnetic field, the coils of which are connected directly in series with the motor. As the pressure in the reservoir falls from 5 to 7 lbs., the piston is forced back by the spring, the contacts are pushed down to their seat, the circuit is closed, current flows to the motor and the compressor starts. The circuit remains closed until the pressure reaches normal when it overcomes the force of the spring, forces the piston upward, breaks the contact and the motor stops. This operation is repeated automatically, the machine requiring practically no attention. The governor can be adjusted to any pressure from 45 to 100 lbs. and works on a difference of from 5 to 7 lbs.

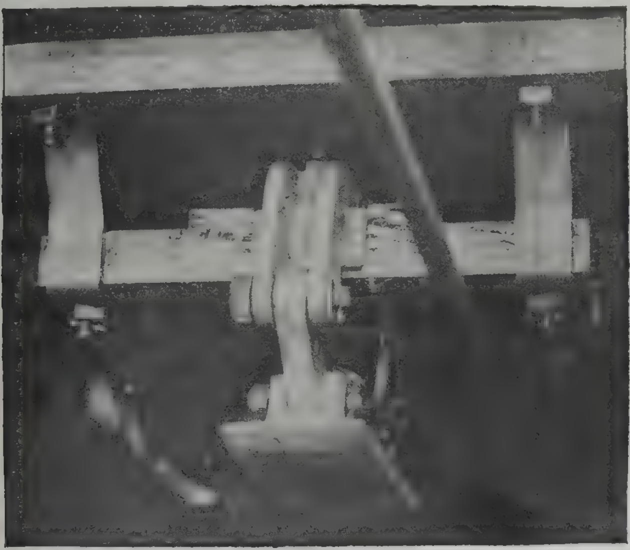

Fig. 3.—Cast-Iron Contact Shoe in Position; N. Y., N. H. & H. R. R.

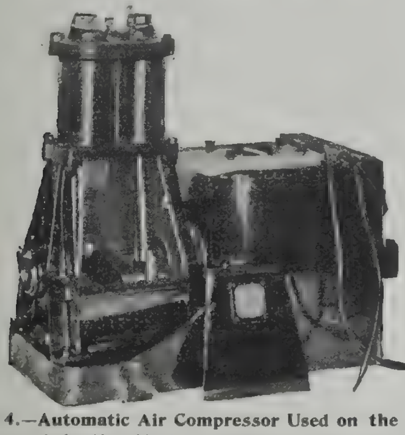

Fig. 4.—Automatic Air Compressor Used on the Electric Cars of the New York, New Haven & Hartford R. R.

Before the third rail was installed two steam locomotives were used on the $3\frac{1}{2}$-mile stretch from Nantasket Junction to East Weymouth. These locomotives burned each day four tons of coal apiece. With the new arrangement not more than four tons are used to generate power for the entire seven miles between Pemberton and Nantasket Junction. Trains have been operated at a speed of 70 to 80 miles per hour.

We are indebted to the General Electric Co. for the accompanying illustrations and the information from which this article was prepared.

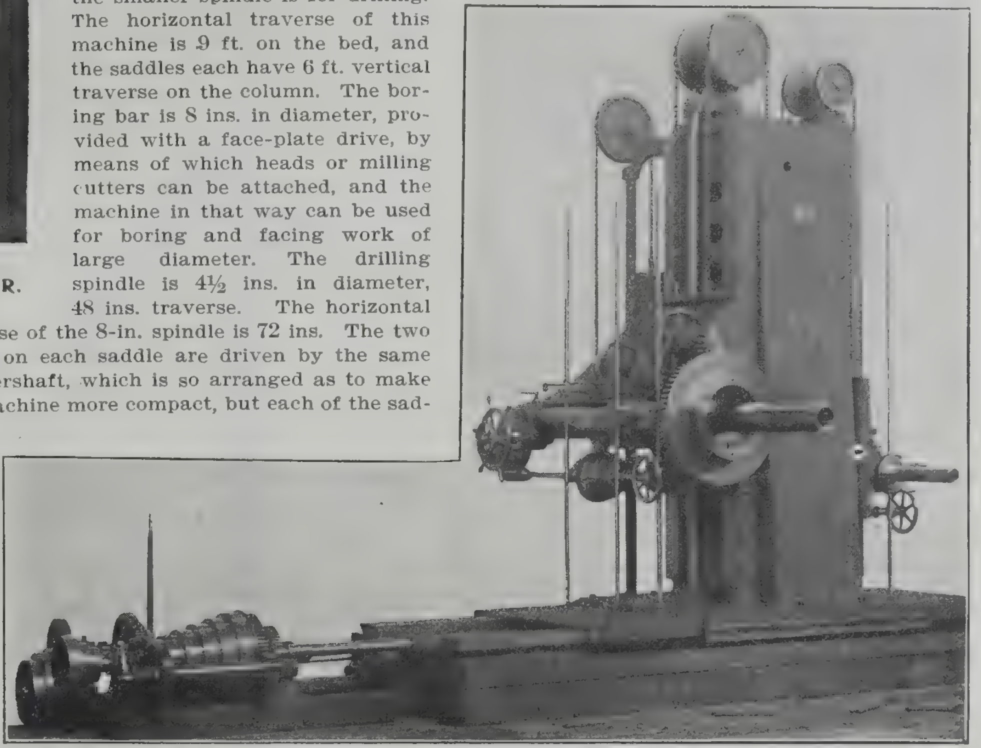
A HEAVY HORIZONTAL BORING, DRILLING AND MILLING MACHINE.

We illustrate herewith a powerful two-spindle horizontal boring, drilling and milling machine, recently built by The Niles Tool Works Co., of Hamilton, O. The cut shows the machine without the floor tables. These are attached to the bed. They are made either square, circular or rectangular in shape, as may be desired, for the particular work that is to be done on the machine.

The column is traversed on the bed, and is supplied with two saddles on opposite sides of the column. The saddle with the large spindle is for boring purposes, and the smaller spindle is for drilling. The horizontal traverse of this machine is 9 ft. on the bed, and the saddles each have 6 ft. vertical traverse on the column. The boring bar is 8 ins. in diameter, provided with a face-plate drive, by means of which heads or milling cutters can be attached, and the machine in that way can be used for boring and facing work of large diameter. The drilling spindle is $4\frac{1}{2}$ ins. in diameter, 48 ins. traverse. The horizontal traverse of the 8-in. spindle is 72 ins. The two heads on each saddle are driven by the same countershaft, which is so arranged as to make the machine more compact, but each of the saddles are independent of one another in every respect, and are so connected with the driving shaft (which is of large diameter) that either one or the other of the spindles may be thrown out at will. The driving cone is provided with six steps, and is powerfully back-geared. Each of the spindles is nicely counterweighted, and all the feeds and movements of the saddles are within easy reach of the operator, a platform being provided close to each saddle. The weight of this machine is about 80,000 lbs., without any floor plates. It is particularly adapted for large floor plates. It is particularly adapted for large engine work, electric generators, ship building, etc.



HORIZONTAL BORING, DRILLING AND MILLING MACHINE.

A DOUBLE-BLADE SEMAPHORE FOR BLOCK SIGNALING ON THE PARK AVE. VIADUCT; N. Y. CENTRAL R. R.

The new four-track steel viaduct of the New York Central R. R., in New York city, which extends from 110th St. to and beyond the Harlem River, will have a very complete system of lock-and-block equipment, and all the signaling and interlocking plant has been installed by the National Switch & Signal Co., of Easton, Pa. On this viaduct the two western tracks are used for northbound trains and the two eastern tracks for southbound trains, the trains keeping to the left on this part of the line in consequence of the arrangement of the Grand Central terminal station at 42d St. The first signal station for the viaduct line is at 110th St., and this has 12 levers, operating 4 double-blade signals, 4 distant signals and 4 torpedo signals. The station at 125th St. has 22 working levers, operating 8 double-blade signals, 6 distant signals and 4 mechanical slots. The great four-track drawbridge, 400 ft. long, which crosses the Harlem River, between 133d and 135th Sts., is protected by signals controlled from a tower at 135th St., on the north side of the river.

In designing the signal plant, one requirement to be met was that of the officers of the railway to the effect that the system of lock-and-block working which has been in operation for some time in the Fourth Ave. tunnel, should be extended as far as 135th St. Pot signals are used in the tunnel, showing three colors; green, red and white. The block instruments used to control these pot signals are double instruments controlling two levers, and since the two levers operate the same signal, it was necessary to design a movement which would permit of the two levers operating on the same line of connections to the same signal. This was successfully carried out in the tunnel, and since all the signals on the elevated structure are high semaphore signals, it became necessary to design a special signal for that work.

Before proceeding further with the description of the special form of signal designed to accomplish the desired end, it is necessary to explain the purpose of using both red and green. It has been found desirable to use the red and green in the lock-and-block system so that in case of failure of the track circuit or apparatus operating and controlling the signal preventing the giving of a clear signal, it would be possible to pass trains over the road by clearing the red (or "stop") signal, leaving the green (or "caution") signal in the horizontal position. This indicates to the engineman that while both arms are not in a clear position he may proceed since the red signal was cleared, knowing that the only reason he does not receive the white signal is that the apparatus is out of order. It might seem that this is a condition which it is hardly necessary to provide against, but owing to the enormous volume of traffic on these four tracks (which carry all the trains of the New York Central R. R. and the New York, New Haven & Hartford R. R.), it was found that notwithstanding the most careful supervision of the work there were times when trains would be delayed unless this compound signal, as it might be termed, was operated. This is not really permissive signaling, for the red signal cannot be cleared unless the section in advance is unoccupied, but it is a special system introduced in order to provide for the prompt and safe handling of a very heavy traffic. This plan, it will be seen, avoids the necessity of stopping each train while the fireman goes to the signal tower for a green caution card to allow the train to pass the red signal under "caution" as far as the next signal tower. There are two separate circuits, one for each signal (the white and the green) so that it is impossible for an operator finding he cannot give the "white," and assuming that the apparatus is out of order, to give the "green" when as a matter of fact there is an obstruction on the track.

The following rule for signalmen governing this is included in the rules issued over the signature of Mr. J. H. Franklin, General Manager of the Harlem Line:

> Give three (3) bells to get unlocked on your red signal. If advance tower fails to unlock you on red you will put your slide in normal position, which is back. Then pull your green slide in center position and give three-one (3-1) to man in advance tower, and he will unlock you on the green lever. If both fail, use the "Clearance Card" and flag the train.

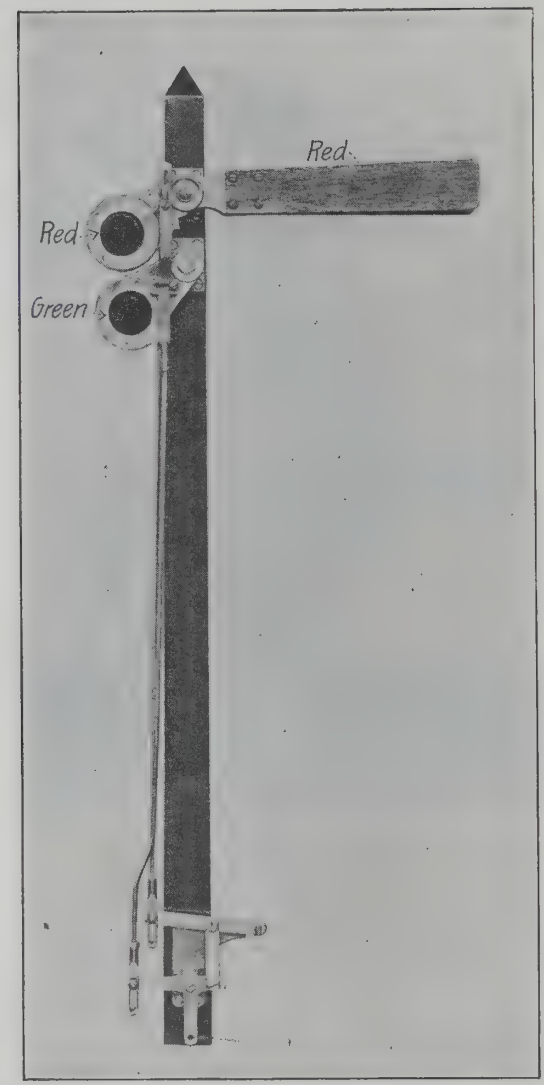

Fig 1.—Normal Position, "Danger."

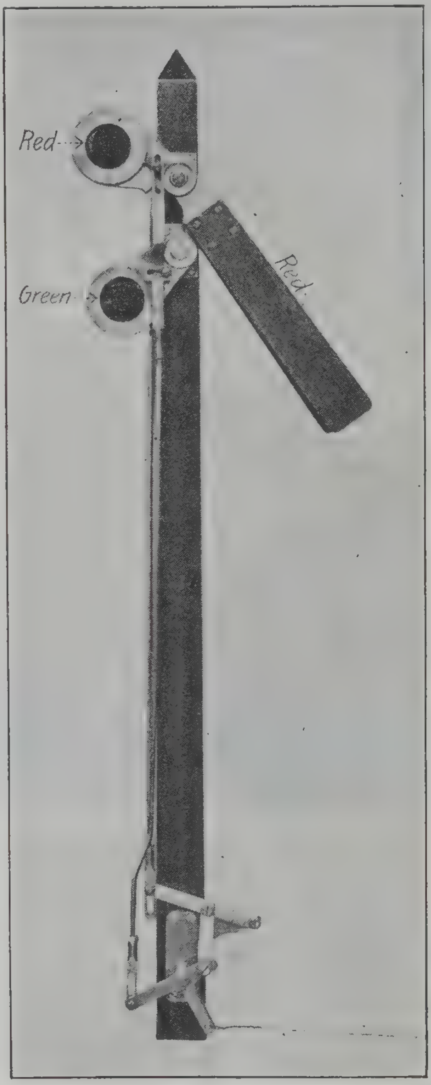

Fig. 2.—Position for "Track Clear."

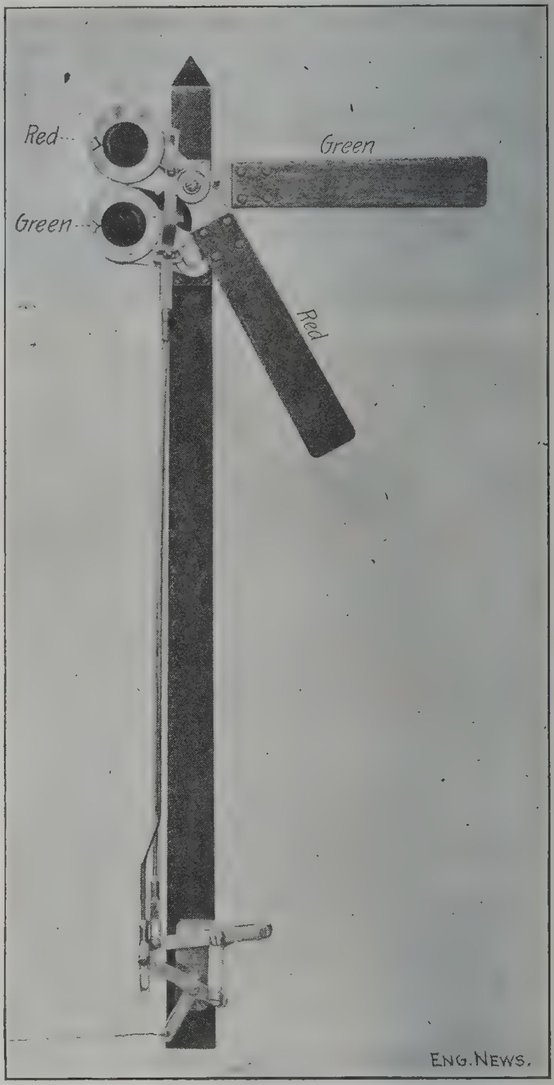

Fig. 3.—Position for "Track Clear," When Signal is Inoperative.

DOUBLE-BLADE SEMAPHORE FOR THE NEW YORK CENTRAL & HUDSON RIVER R. R.

Designed and Installed by the National Switch & Signal Co., Easton, Pa.

The style of double-bladed semaphore signal designed to meet these requirements is shown in the accompanying cuts. Fig. 1 shows the signal at the danger (or "stop") position, with but one semaphore blade visible. Below the regular blade grip will be seen an auxiliary or floating spectacle. There are two up-and-down rods, coupled onto a system of compound levers at the base of the pole. The adjustable jaws on these rods are slotted, as is the top of the outside up-and-down rod where it connects with the blade grip. The floating or secondary spectacle is actuated by a horizontal slot in this up-and-down rod. In the case of the Harlem River work the signal is operated by a single line of pipe. The interlocking machine in the tower has two levers for each home signal, one red and one green, and these levers are coupled to a compound lever below the machine, which in turn is coupled to the rocking shaft.

The normal position of the levers and signal is at danger and in case a clear signal can be given, the operator simply reverses the red lever, thereby clearing both arms as shown in Fig. 2. In case a clear signal cannot be given by reason of any failure in the apparatus, the operator reverses his green lever thereby exerting a pull on the line of connections which lowers the outside or red arm to an angle of 65°, leaving the green blade in the horizontal position as indicated in Fig. 3.

It will be seen by Fig. 3 that the floating spectacle is moved upward to a position in front of the lamp when the green lever is reversed; but when the red lever is reversed, clearing both arms, this spectacle remains in the position shown in Figs. 1 and 2, so that the white light shows between the floating spectacle and the spectacle in blade grip, as in Fig. 2. The blade grip on the green blade is not fitted with glass and simply acts as a counterweight.

Owing to the use of the slot in the adjustable jaws of the up-and-down rod, the reversing of the green lever does not actuate the up-and-down rod connecting with the green blade; while in reversing the red lever, the up-and-down rod actuating the red blade is not moved, the red blade being carried down by a lug on the blade grip of the green blade, which engages with a corresponding lug on the blade grip of the red blade, so that when the green blade is cleared it carries with it the red blade without actuating the floating spectacle.

This style of semaphore signal is applicable for ordinary permissive block signaling. In this case, however, it is not necessary to have two levers in the interlocking machine, as one lever can be made to do all the work, one arm being lowered by the half stroke, and both arms by the full stroke of the lever. This can be operated with either pipe or wire, but for block signal stations where the expense would be but little greater if pipe were used, the use of pipe is recommended as giving a more positive connection.

THE ANNUAL CONVENTION OF THE AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.

The third annual convention of this society was held in Chicago, Oct. 14, 15, 16 and 17, 1896, and proved very successful both socially and in the character and variety of the technical papers and discussions. The total attendance was about 150 members, about half of whom were in constant attendance at the meetings. Altogether 21 papers and 6 reports of committees were considered during the six working sessions, rather too large a number for the proper discussion of all, yet by grouping the reports and papers on the same subject and discussing them in a body instead of individually the time was used to the best advantage. Some time was lost in irrelevant discussion, but the presiding officers kept such discussions pretty well in hand, all things considered. The discussions also lost something in interest through the fact that the members had to base their remarks upon what they could catch from hearing the papers read. It is to be hoped that the society will be in a condition by another year to have the papers printed and distributed to the members some time in advance of the convention.

The opening session on Oct. 14 was devoted to routine business and the usual addresses of the President and others. Mayor Geo. B. Swift, of Chicago, welcomed the convention to the city with a few brief remarks. Mr. Geo. G. Benzenberg, M. Am. Soc. C. E., the president of the society, then presented his annual address. Mr. Benzenberg called attention to the fact that the society's object was not so much to secure better city government as it was to secure to the citizens and taxpayers of such municipalities the most economical and best class of public improvements obtainable. He continued in part as follows:

> Millions of dollars are annually expended in reconstruction too frequently made necessary by the introduction of improper material, imperfect plans or by the lack of information and experience of those into whose hands such work has been intrusted. It is not to be supposed that the conditions largely responsible for such state of affairs are likely to be remedied, excepting through the slow process of development towards a more stringent and accountable administration of public affairs. With such evolution, however, this society has no connection, its object being distinctly to improve our competency and efficiency in the discharge of our respective duties by the interchange of experience, by the presentation and discussion of papers, and by preserving in our proceedings for mutual reference and study such practical information as may be collected.
>
> Although meeting to-day for the third time, this society was not fully organized until at its last meeting in Cincinnati, nor were its objects fully set forth nor its work intrusted into the hands of committees until at that meeting, hence no organized work of the convention was possible until now. The faithful and arduous work of the committees, represented in their reports at this meeting, indicates what may be accomplished by systematic and careful investigation, and the numbers and subjects of the papers to be presented demonstrates clearly the interest of our membership in the questions most prominent in municipal improvements to-day. This work, however, should be expanded, taking in every kind of municipal government in all its legislative and administrative branches, uniting them all into one organization whose work could be divided into sections under each department head, considering all topics not only in the entirety but in all its details, for it is the latter that most frequently puzzle the inexperienced in our smaller cities where growth demands new improvements. The best methods of selecting paving bricks, of testing sewer pipes, paving and other cements, the most satisfactory and economical system of cleaning streets, of collecting garbage and ashes, of cleaning or flushing sewers, the best manner of regulating the too promiscuous opening of street pavements by corporations and individual property owners, of introducing protective sanitary measures in all house plumbing and draining, of securing the best railway track construction in streets, the abatement of smoke and other nuisances, the regulating of traffic by a wagon or tire tax, of providing the best kind of underground service for all classes of wires, of securing to the public a suitable return for all corporate franchises, of enforcing honest competition and honest work on the part of contractors for public works, are some of the questions in which all are interested and many of us seek the experience of other cities.
>
> The rapid development and growth of many cities make necessary that municipal improvements assume a more permanent and durable character, obviating the necessity of frequent reconstruction. Temporary expedients in municipal work are too frequently expensive mistakes and should be always discouraged. It is preferable that progress in improvements be slow so they assume a permanent character and relieve the property owner as much as possible from the burden of reconstruction. Such practice, of course, is not always in the first instance approved of by the taxpayer, but there is no lack of object lessons to demonstrate its economy. Our efforts as an organization should be exerted in that direction and its work will be more readily appreciated by the citizens when they observe that perfection, durability and economy are the motives which direct our convention labors. Much study and committee work will be required to sift out the best methods and results from the different local experiences.

The report of the Secretary and Treasurer showed the society to be somewhat in debt, but in such a condition that the coming year with its increased membership might see the debt cleared away. To provide for future contingencies it was decided to consider at the next meeting the revision of the constitution so as to increase the annual dues from $3 to $5.

In the afternoon session the business of reading and discussing the committee reports and papers was begun. These were divided under the following heads: Street Paving, committee report and twelve papers; Electric Street Lighting, committee report and one paper; Sewerage and Sanitation, committee report and two papers; Water-Works and Water Supply, committee report and five papers; report of committees upon Taxation and Assessment, and City Government and Legislation; paper on Garbage Disposal at Milwaukee. In this report of the proceedings of the convention only a brief summary of the various papers and the discussion which followed them will be given, but in future issues it will be the purpose to present some of the papers in more extended form.

Street Paving.

The consideration of this subject was opened by the presentation of the corresponding committee report by Mr. A. D. Thompson, City Engineer, Peoria, Ill., Chairman. Its substance was that the committee had deemed it best at the present session to devote its attention simply to securing papers covering different branches of the problem. Twelve such papers had been secured and would be presented.

Under the title of "Advantages of an Asphalt Testing Laboratory," Mr. N. P. Lewis, Brooklyn, N. Y., described the asphalt testing laboratory established in that city at a cost of some $2,500. Although recently installed this laboratory had shown its value in many respects and gave promise when the analyses and tests had progressed further, of furnishing much valuable data for the use of the department. A paper on "Specification Requirements for Asphalt, Asphalt Mixtures and Tests for Asphalt," by Mr. A. W. Dow, Inspector of Asphalts and Cements, Washington, D. C., was read by title and will be further considered in another issue. Two papers of a descriptive character followed: One entitled "Paving Street with Brick," by J. S. Hathaway, Chairman Street Committee, Marietta, O., and the other entitled "Paving in Nashville, Tenn.," by J. L. Kennedy, Member Board Public Works, Nashville, Tenn. Mr. F. W. Cappelen, City Engineer, Minneapolis, Minn., in a paper entitled "Modern Street Railway Track Construction on Asphalt Paved Streets in Minneapolis," described the special methods of track construction adopted in the city mentioned. Some of the particular features of this work will be presented in a future issue. The paper following was by Mr. A. D. Thompson, City Engineer, Peoria, Ill., entitled "Testing of Paving Brick," and described the absorption, transverse breaking, and abrasion tests adopted in the city mentioned and already described in Engineering News.

Two papers discussing regulations for opening street pavements were read by Capt. Lansing H. Beach, U. S. Engineer Corps, Washington, D. C., and Mr. G. D. Snyder, City Engineer, Williamsport, Pa. Capt. Beach gave in much detail the laws and regulations governing the opening of pavements in the National Capital, where the restrictions were very stringent as compared with most other cities. In Williamsport the idea followed is to anticipate future openings as far as possible by requiring all improvements to be made before the pavement is laid. When openings are necessary the permit is charged for at the rate of the original cost per square yard of the pavement to be opened. In replacing the pavement the person opening it is required to fill the trench as thoroughly as possible, and then, whatever the foundation of the original pavement, to lay a concrete foundation spanning the trench for the new pavement. This construction had been fairly satisfactory in preventing settlement.

In a paper on "Rumbling of Brick Pavements," Mr. E. Adam, Engineer Board Street Commissioners, Newark, N. J., described the troubles of this nature experienced in the city mentioned. He found that the rumbling occurred on pavements with grout filling, but not on pavements with sand filling, and was disposed to attribute the cause to expansion which raised the pavement from its foundation. A paper on "Improved Streets and Their Care," by Col. M. A. Downing, Chairman Board of Public Works, Indianapolis, Ind., followed next and described briefly the work of the city named in the matter of street paving. Practically all the work of improving streets in Indianapolis had been done within five years, and that city now had, exclusive of the work done in 1896, 28 miles of asphalt, 15 miles of brick, 5 miles of wood block and 2 miles of macadam. These pavements, except in a few suburban streets and in alleys, were laid on a 6-in. concrete foundation. In suburban streets 4 ins. of concrete were used and in alleys broken stone. Brick pavements did not find much favor, partly from the fact that poor material had been used. At present wood block pavement was favored. Yellow pine blocks, 4 × 6 × 9 or 12 ins., creosoted with 12 to 14 lbs. of creosote per cubic foot, laid on a 6-in. concrete foundation were used. The final paper on street paving was by Mr. E. B. Guthrie, Chief Engineer, Buffalo, N. Y., and was entitled "Cost of Repairing Asphalt Pavements." As the information given was largely in the form of tables it will be considered separately at a future time.

Discussion.

The discussion which took place on the papers presented was somewhat discursive, and neglecting its order of occurrence it is here collected under separate heads as far as practicable.

Asphalt Pavements.—Mr. N. P. Lewis, in response to questions, stated that chemists were not agreed as to what chemical action took place when carbonate of lime was added to asphalt. Physically it filled the voids, made the pavement harder and consequently tended to make it more slippery. The experience with the testing laboratory at Brooklyn had not yet been long enough to enable a certain determination whether a sample was lake or rock asphalt, but it indicated that the relative percentages of petroline and asphaltine might be a good determination. The use of asphalt in Brooklyn had been too short to enable a determination as to whether rock or lake asphalt was the better, but the major part of the pavements now laid were Trinidad lake asphalt. The cost, exclusive of curbing, of a pavement made up of a 6-in. concrete foundation, ½-in. cushion coat, and 2 ins. wearing surface, was $2.54 per sq. yd. for a 24-ft. roadway; cost of a 1-in. cushion coat and 2-in. wearing surface laid over old cobblestone pavement on a 34-ft. roadway, was $1.84 per sq. yd.

Mr. L. W. Rundlett, City Engineer, St. Paul, Minn., stated that the lowest cost for asphalt pavement in that city had been $1.95 per sq. yd. A five-year guarantee was required. Mr. A. D. Thompson, City Engineer, Peoria, Ill., stated that in Peoria, Ill., asphalt pavement, 6-in. concrete foundation, ½-in. binder, and 2-in. wearing surface cost from $1.84 to $1.90 per sq. yd. A five-year guarantee was required. Mr. E. B. Guthrie, Chief Engineer, Buffalo, N. Y., stated that for the last two or three years the asphalt paving in that city had cost about $2.45 per sq. yd. Mr. Geo. H. Benzenberg, City Engineer, Milwaukee, Wis., stated that pavement with a 6-in. concrete foundation, 1-in. binder, and 2-in. wearing surface, excluding curbing and deducting spaces for manhole covers, etc., but including grading, cost from $1.95 to $1.99 per sq. yd. This was pavement in streets having no street railway tracks, but in streets having such tracks, 7 ins. of concrete, 1-in. binder and 2-in. wearing surface was used, with a 20-in. brick gutter on each side, and cost $2.31 to $2.34 per sq. yd. This included laying a granite course along the inner line of tracks, stone being furnished by the railway company. The railways were also required to maintain the pavement between tracks and 1 ft. outside of outer rails. If the stone courses were not used unsatisfactory results followed. These also occurred when the cross ties and rails were not laid on a concrete foundation as the oscillation broke up the pavement.

The discussion closed with a brief consideration of what was meant by an asphalt pavement in good repair, which was called out by the fact that trouble occurred with asphalt paving companies as to the meaning of the term when turning over pavement to the city at the end of their guarantee. The opinion of those most familiar with the subject was that rigid specifications should be drawn to cover this point, and a resolution was adopted by the convention asking that a special committee be appointed to present such specifications at the next annual convention.

Brick Pavements.—Practically the whole discussion turned upon the testing of brick and the rumbling of brick pavements, the first drawing out the usual variety of conflicting opinion. Mr. M. L. Holman, of St. Louis, Mo., stated that that city had gone thoroughly into the subject of testing paving brick for the purpose of evolving a practical commercial system of testing. They had even laid pavements and driven horses and wagons over it continuously to discover the real action of traffic. In the laboratory their tests and the results from them had been as follows: The absorption had been rapid at first, but became slower the longer the time, and continuing to a small extent for some months. From the experiments, he concluded that 48 hours could be considered to give a fair test. Abrasion tests were carried out in a 26-in. × 4-ft. foundry tumbling barrel. It was found that by plotting the results a regular curve was obtained which was comparable with other curves obtained from bricks of the same manufacture but not with those of other manufacture. In cross breaking tests it was found that bricks of good quality broke at the center of the span, but poor quality bricks broke irregularly, the break following lines of defect. To determine the interior structure an apparatus had been devised to split the brick. Good quality bricks split straight, while the fracture in those of poor quality followed the lines of defect. Tests were now being made to determine the effects of freezing by artificially freezing the bricks from the top down, just as such freezing would occur in the pavement. As the result of all experiments, he had excluded all but the cross breaking and abrasion tests for practical use. He did not think that the interior of a brick which absorbed more than 2% of water was thoroughly compacted and free from laminations.

In respect to the rumbling of brick pavements Mr. N. P. Lewis stated that they had experienced trouble in Brooklyn, N. Y., and attributed it to the fact that the sand cushion contained frost when the pavement was laid, and when in warm weather the sand thawed a void was left under the pavement. His opinion had been confirmed by reports from other cities, and he could not bring himself to believe that grout filling and expansion had much to do with the trouble. Mr. A. D. Thompson, City Engineer, Peoria, Ill., considered that if the pavement was properly laid no trouble from rumbling need be had with grout filling or any other kind of filling.

Wood Pavements.—The paper describing the adoption of a wood block pavement in Indianapolis and the approval of its continued use by the Board of Public Works of that city raised a somewhat heated discussion. A number of the members were disposed to condole the city on the mistake it had made and cited numerous cases in which wood block paving had been a total failure in this country. It developed in most instances, however, that the cities having these sad experiences had adopted wooden block because it was cheap, if constructed as it usually is constructed in America, and the sand and plank foundations, untreated blocks of cedar and white pine, and improper joint filling, had worked the failure which might have been readily anticipated. In a brief discussion Mr. Geo. H. Benzenberg insisted upon the fact that such wooden block pavements as were usually constructed in this country could not be justly compared with pavements made of sound creosoted or otherwise treated blocks, laid on a concrete foundation with proper attention to joint filling, such as are laid in European cities. He, however, considered that no advantage in cheapness of cost could be expected in wood pavements properly laid. Mr. F. W. Cappelen, City Engineer, Minneapolis, Minn., considered wood block inadvisable on account of cost of maintenance. Where, however, the people were willing to stand this expense no better pavement could be desired. In Europe it was tacitly understood that the blocks were to be replaced every four or five years, but for the other advantages secured the people were willing to pay for this maintenance.

Opening of Pavements.—Although the discussion was quite voluminous on the question of regulating the opening of street pavements by persons and corporations desiring to make gas and sewer connections, etc., it consisted mostly of a relation of troubles and of stating the urgency of more stringent laws. Mr. N. P. Lewis, of Brooklyn, N. Y., stated that it was the practice of that city when about to lay a new pavement to give 15 days' notice to all persons to complete their improvements in advance. After the pavement was once laid no permits were allowed for a period of five years for asphalt and brick pavements, or three years for other kinds. This could not be enforced. At present the cost of permits for street openings is $13 from March to December and $18 for the remainder of the year. In the city of New York the least charge was $4.50 per sq. yd. and no permit was granted for less than a 4-sq. yd. opening. In further discussion it was developed that many states had laws authorizing connections to be carried to the curb lines at the time of constructing the pavement.

Electric Street Lighting.

The consideration of this subject comprised an elaborate committee report and a paper by Mr. J. A. Cabot, City Electrician, Cincinnati, O., entitled the "Municipal Control and Inspection of Electrical Construction in Cincinnati." The report consisted of a tabular statement of plant, operating expenses, cost, etc., of the electric street lighting plants in upwards of 100 American cities and will be considered in a future issue. Only a brief discussion followed the report and papers, and this consisted mostly of replies to questions regarding misunderstood points in the report and paper.

Sewerage and Sanitation.

The committee on this subject had no formal report to present but had secured two papers which were then read. Capt. Lansing H. Beach, U. S. Engineer Corps, Washington, D. C., presented the first of these under the title of "Construction of Pipe Sewers to Prevent Root Intrusion." In the city of Washington, D. C., the great abundance of shade trees had caused much trouble from the roots getting through the joints into the sewers and otherwise disturbing them, and a special construction had to be adopted to overcome the difficulty. The plan adopted was to bed the pipe in concrete on the bottom and sides and at the joints to carry a 4-in. thick ring of concrete over the top. Hub and spigot joints were not used in this construction, which had been very efficient for the purpose intended. The second paper under the head of sewerage was read by Mr. G. L. Clausen, Superintendent Sewer Department, Chicago, Ill., and described the "Sewers and Sewage Disposal of Chicago." The paper was a relation of subject matter already familiar to our readers. The discussion on the papers proper was brief and needs no extended mention. Mr. Geo. H. Frost, of Engineering News, described at some length the sewage disposal system constructed under his direction at Plainfield, N. J., and already fully described in these columns, and called attention to the fact that with the growing stringency of legislation regarding the pollution of streams, this and similar methods of disposal should be carefully studied by engineers.

Water-Works and Water Supply.

The report of the committee on this subject was read by the Chairman, Mr. H. Van Duyne, Newark, N. J., and consisted in a summary of the features particularly needing study. Among these the report mentioned particularly, growth of algae and other organisms, trouble from anchor ice at all gate houses, and sewage pollution. Four papers followed this report, of which those on "Water-Works at Nashville, Tenn.," "Filtration of Water Supply at Davenport, Iowa," and "Biology of Water, Microscopical Organisms and the Determination of Quality," covered features already made familiar to our readers in previous issues. The fourth paper was by Mr. John W. Hill, M. Am. Soc. C. E., Cincinnati, O., and took up the question of the purification of "Water Supply in Eight Cities in Relation to Typhoid." A description of the methods of water purification at Berlin, Zurich, The Hague and Liverpool was given and compared with the lack of such methods in New York, Philadelphia, Cincinnati and Chicago. Comparisons were drawn between the death rates by typhoid of these cities, in which perhaps the most notable fact was that Chicago showed the worst conditions, its typhoid death rate being for the past five years 10½ times that in Berlin. No discussion followed these papers.

Under this same head came the paper on "Method of Treating Garbage in Milwaukee," by Dr. Walker Kempster, Commissioner of Health. This plant has already been fully described in Engineering News, as has also the plants at Buffalo, N. Y., and Cincinnati, O., which were described in the discussion which followed. The discussion brought out nothing concerning these plants which we have not given in the articles mentioned.

City Government.

Under this head came two reports of committees on "Taxation and Assessment" and "City Government and Legislation," both of which were very elaborate and entered into the general discussion of broad questions of law and municipal management too extensively to be taken up here. They elicited no discussion.

Election of Officers.

The election of officers for the society for the coming year took place on the second day of the convention and resulted in the following selections: President, August Herrmann, President Board of Administration, Cincinnati, O.; First Vice-President, E. B. Guthrie, M. Am. Soc. C. E., Chief Engineer, Buffalo, N. Y.; Second Vice-President, Wm. R. Kerr, Health Commissioner, Chicago, Ill.; Third Vice-President, E. Adam, Engineer Board of Street and Water Commissioners, Newark, N. J.; Secretary, D. L. Fulton, Superintendent of Sewers, Allegheny, Pa.; Treasurer, J. L. Kennedy, Nashville, Tenn.; Finance Committee, L. W. Rundlett, City Engineer, St. Paul, Minn.; A. F. Monroe, Chairman Public Works, Omaha, Neb., and F. J. O'Brien, Superintendent Public Works, Oswego, N. Y.

Committees were appointed to report at the next annual convention upon the following subjects: Street Paving, Electric Street Lighting, Sewerage and Sanitation, Water-Works and Water Supply, Taxation and Assessment, City Government and Legislation, Disposition of Garbage and Street Cleaning, Reviews. The place selected for the next place of meeting was Nashville, Tenn.

Excursions and Entertainments.

Several excursions and entertainments were arranged by the local committees for the pleasure of the convention members. On Oct. 15 an excursion along the line of the Chicago Drainage Canal was tendered by the trustees of that work, and on Oct. 17 an excursion to the water-works intakes by boat and a coach ride through the South Side parks and boulevards took place. On the evening of Oct. 16 a banquet was tendered to the members by the local committee. These various entertainments were participated in by the majority of the delegates present and were thoroughly enjoyed.

BOOK REVIEWS.

A TEXT-BOOK ON GAS, OIL AND AIR ENGINES, or Internal Combustion Motors without Boiler.—By Bryan Donkin, M. Inst. C. E. Second edition. Revised and largely Rewritten. London, 1896. Chas. Griffin & Co., Limited. 8vo.; pp. 500; 154 illustrations.

This work, by a well-known English engineer, is the standard work on its subject. The present edition brings it up to date. It is a very complete treatise, including the history, theory, practice, bibliography, list of patents, etc., A table in the appendix contains the principal results of 147 tests of gas, oil and air engines from 1878 to 1895.

A PRACTICAL TREATISE on Segmental and Elliptical Oblique or Skew Arches, setting forth the principles and details of construction in clear and simple terms. By George Joseph Bell, County Surveyor and Bridge Master of Cumberland. London and New York. E. and F. N. Spon and Spon & Chamberlain. 8vo.; 125 pp.; 8 plates. $8.40.

The author aims to simplify the rules of construction for oblique arches, and devotes pages of text to a description of the mathematical processes to be gone through with. Close attention to these directions will doubtless enable an engineer to build an oblique arch—if he must, but the plates are chiefly elevations of plans of such arches as built and have little value to the student. It is to be regretted that the author did not indulge more in illustrative matter relating to the practical application and the appearance of the various necessary templates. The construction of arches of this type is rarely called for in the United States; and when the occasion does arise both the engineer and the stone-cutters have to be initiated in what may be simple work to Mr. Bell. This detail is just what he has omitted, and it is the only part that would warrant a new treatise on a rarely applied art, in this country at least.

ELEMENTS OF MECHANICS, including Kinematics, Kinetics and Statics. With Applications. By Thomas Wallace Wright, M. A., Ph. D., Professor in Union College. New York: D. Van Nostrand Co. London: E. & F. N. Spon. 12mo.; pp. 372. $2.50.

This book, the author states in the preface, is a completely rewritten edition of his "Text Book of Mechanics." The sections on graphical methods have been extended. Machines have been discussed in greater detail. New problems and illustrations have been added throughout. To each chapter is appended a series of examination questions on the text preceding or capable of being easily deduced from it. No mathematics has been introduced beyond the elementary principles of geometry, trigonometry and the calculus. The book is so arranged that the sections involving calculus may be omitted without disturbing the continuity, and thus a more elementary course be taken. The British and metric gravitation systems of units and also those of the C. G. S. system, with their dimensions, are all fully treated.

We find a great deal to commend in this book, and in the hands of a skillful teacher it should prove an excellent text book. The explanations are in general very clear, and the great number of practical examples for numerical computation will prove an admirable exercise for the student. We regret, however, that the author has fallen into the pitfall which has been prepared for all modern writers of mechanical text books by those scientists who have injected into the literature of the subject new terms and definitions and new methods of theorizing. With the various gravitation units, British and metric, the absolute or C. G. S. (centimeter, gramme second) and the M. K. S. (meter, kilogramme second) with their "dimensional" formulas, in which force is defined as a function of length, mass and time with a negative exponent, and with a great number of new units, such as megalergs, kines, boles and spouds, it is no easy matter for any author to steer a clear course, and at the same time make his text consistent with his definitions and clear enough to be understood without a great deal of labor. That the present author has made an earnest effort in this direction is apparent, but he has not been very successful. In his preface he tells us that he uses the term "centrifugal force," although there are objections to it, because as all engineers use the term it will not do to ignore it. On the other hand, he confines the use of the term mass to the absolute system of units only. It is not easy to see why he does not use it in the sense in which all engineers who have studied Rankin use it, namely, as the quotient of the weight of a body divided by the factor g, or the acceleration due to gravity. With the more recent writers he begins the study of the subject with velocity instead of with force. The second chapter treats of Newton's laws of motion, and in it we find his first definition of force in these words:

> From the law (Newton's first law) we also learn that by the term force is meant a cause of change in motion, not in the sense of moving agent, but in the sense of antecedent. Force is thus not to be regarded as the cause of a state of motion, but of a change of state, from rest to motion, motion to rest, or to an alteration of motion—in a word, of acceleration. Whenever force acts an acceleration of the motion of the body acted upon is produced.

To say that force is not to be regarded as the cause of a state of motion, but as the cause of a change of state from rest to motion, is a verbal splitting of hairs which is highly objectionable in a work of this kind, but the last sentence in the above quotation is unpardonable, for it is untrue except when the force is unbalanced and the body is free to move.

Under Unit of Energy we find the following:

> The unit of energy must be the same as the unit of work. In the British system the unit is therefore the foot-pound. Note that unit kinetic energy is not the energy of unit weight (1 lb.) moving with unit velocity (1 ft. per sec.), but only one-half that quantity.

The expression "unit kinetic energy" is a bad example of the prevailing tendency to define "units" of every conceivable kind, compound as well as simple. If the unit of energy, kinetic or other, is one foot-pound, and the formula for energy is $\frac{1}{2} w v^2 \div g$ then the energy of a body whose weight is 1 lb. and whose velocity is 1 ft. per second is $1 \div 2g$ foot-pound. According to the author's statement, "unit kinetic energy" is one-half of this quantity or $1 \div 4g$. No doubt he does not mean this, but this is our understanding of his language.

Further on we find this, under Conservation of Energy:

> It is perhaps more in accordance with the spirit of modern science to consider space, time, matter and energy as the fundamental concepts of mechanics rather than space, time, matter and force. * * * The latter method, which is that followed in this book, is given as being more readily appreciated by the beginner. But as it involves difficulties from which the first is free it seems likely that the notion of energy will in time be adopted universally as the fundamental one rather than that of force.

We think the author has done well in following the second notion spoken of, in considering force and not energy to be the fundamental concept. If it is "more in accordance with modern science" to consider energy as the fundamental concept, then it seems to us that modern science is science run mad. Force, defined as anything which tends to cause motion, such as a push or a pull, is a fundamental concept which can be appreciated by any student, but energy, whether defined as F S, the product of the acting force into the distance through which it acts, or as $\frac{1}{2} M V^2$, or half the product of the mass into the square of the velocity, is a compound concept, and its measure can only be given in a compound unit, such as a foot-pound. Consider one of the simplest cases of mechanical action, an apple falling from a tree. We have as fundamental ideas in mechanics the matter, mass or weight of the apple, the attraction of gravitation, or the force which causes it to fall, the space or distance through which it falls, and the time during which it falls. We cannot calculate its energy without considering at least two of these elements, the weight and the distance, or the mass (weight $\div$ g) and the final velocity.

We have expressed ourselves thus at length upon this subject because we consider it is high time that a protest should be made against one of the tendencies of "modern science," which is the introduction into literature of new and unnecessary terms, definitions which are lacking in clearness and precision, and in many cases contradict those which have been approved by the usage of generations of scholars, and "fundamental concepts" which are contrary to common sense. If there is any science which should be kept free from such innovations it is mechanics, a science which is practically as finished and unprogressive as geometry. No new facts are likely to be developed in it in the next century, and the method of presenting it which was in use 20 years ago can scarcely be improved on. The only change that can be made is that which is attempted by some writers who are introducing the innovations, and are apparently trying to make mechanics not a useful tool for engineers, but a branch of metaphysics, in which discussion of "concepts" takes the place of exemplification of facts.

LETTERS TO THE EDITOR.... ....281, 282
- A New Mississippi River Dredge—Correction—The Cement for the Melan Bridge at Topeka, Kan.—Noisy Brick Pavements.

THROUGH TRAINS OVER THE BROOKLYN BRIDGE, connecting with the elevated railways and street car lines on either side, were considered at the meeting of the Bridge Trustees Oct. 26. Mr. Wurster, mayor of Brooklyn, spoke strongly in favor of some definite steps being adopted instead of continually postponing consideration of the question. It was eventually decided to employ three engineers, who, together with Mr. C. C. Martin, the Chief Engineer, will form a board of engineers to examine the bridge and settle once for all the feasibility of through and continuous traffic; the sum of $3,000 was ordered appropriated for this purpose. Two engineers are to be selected by the mayors of the two cities, and the third one by the vice-president or president of the Board of Trustees. Mr. Howell, the president, has appointed Mr. L. L. Buck, M. Am. Soc. C. E., who is chief engineer of the new East River Bridge.

◆

PNEUMATIC TUBES FOR CARRYING MAILS are to be laid across the Brooklyn Bridge, connecting the main post-offices of New York and Brooklyn. There will be two 8-in. tubes, the terminals and power plant being in the two post-offices. The right to lay the tubes has been granted to the New York Mail & Transportation Co., at a rental of $1,000 per year for five years. The work is to be done under the supervision of Mr. C. C. Martin, Chief Engineer, and is to be completed by March, 1897. The company will receive $14,000 per year from the government.

◆

AN EAST RIVER TUNNEL RAILWAY to connect New York and Brooklyn is now proposed by the New York & Brooklyn Ry. Co. The tunnel tracks are to come to the surface at each end, to afford direct connection with other lines. The proposed tunnel is to run from the junction of Myrtle and Willoughby Aves., Brooklyn, across the East River, in almost a straight line, parallel to the Brooklyn Bridge, to the New York terminus, at Park Row and Ann St. It will be lighted by electricity. The general plan is to have two tracks in two tunnels, thus making a four-track line. These tunnels will be 8,700 ft. long, and the two tunnels together will be 45 ft. wide. The grade at either end will not be more than 4%. This is the project which has been brought forward from time to time by Mr. B. S. Henning, who is President of the company. The directors include Emerson McMillin; Silas B. Dutcher, President of the Hamilton Trust Co., of Brooklyn; J. N. Partridge, President of the Brooklyn City & Newtown Ry.; Henry W. Slocum, former President of the Coney Island & Brooklyn Ry., and James C. Church, Secretary of the Nassau Electric Ry.

◆

THE NEW EAST RIVER BRIDGE contract for the New York tower has been awarded to Patrick H. Flynn, of Brooklyn, for $367,000, under a bond of $250,000. The stone is to come from the New Jersey quarries of Jesse S. Carman. The engineer's estimate for building this tower was $477,000.

◆

AN AIR-BRAKE PATENT SUIT is now being argued in the U. S. Supreme Court, though that court does not often take up patent suits. The case is that of the Westinghouse Air-Brake Co. against the Boyden Brake Co. The case was carried to the Supreme Court on a writ of certiorari from the appellate court of the fourth circuit at Richmond.

◆

THE LOOP TERMINAL of the Chicago elevated railways, described in our issues of July 16 and Aug. 20, is now to be pushed to completion, the Supreme Court having decided that the property owners along the line cannot prevent by injunction the building of the line.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week, and the most serious accident which we have had to record for some time, was a head collision, Oct. 25, on the St. Louis & San Francisco R. R., near Meramec Highlands, St. Louis, Mo. The second section of a westbound excursion train for St. James, Mo., had orders to stop at the Windsor siding to pass an eastbound accommodation train from Valley Park. The engineman, however, tried to reach the next siding, with the result of causing a collision, in which eight persons were killed and 16 injured. The eastbound train was composed of a combination passenger and baggage car and one day car. The westbound train was composed of a combination baggage and refreshment car, and ten day cars. The first two cars of this train were telescoped and smashed, and in them occurred most of the casualties.

◆

TWO RAILWAY DRAWBRIDGE ACCIDENTS are reported. On Oct. 20, while the drawbridge which spans the guard lock of the Morris Canal, at Dover, N. J., where the canal crosses the Rockaway River, was being raised to allow a canal boat to pass, a work train on the High Bridge branch of the Central R. R. of New Jersey backed down upon it. The rear car, a combination car, filled with laborers, ran half-way up the draw, which was tilted at an angle of about 45°, causing the bridge to fall, but nobody was injured.——On Oct. 26, the theater train from New York, on the New York, New Haven & Hartford R. R., was derailed by the derailing switch at the drawbridge at South Norwalk, Conn. Owing to the speed of the train, it ran through the sidetrack and the engine and baggage car went down a 50-ft. bank, but nobody was hurt. An investigation will be made to ascertain whether the accident was due to a wrong signal or to a failure to observe the signals.

◆

A RUNAWAY CAR on a cableway at the works of the Pioneer Electric Power Co., near Ogden, Utah, struck one of the posts and two persons were thrown out and injured. The accident was due to a failure of the brake on an incline 300 ft. long.

◆

THE COLLAPSE OF A RAILWAY BRIDGE on the Chicago Great Western Ry., over the Platte River, occurred Oct. 21, while a freight train was crossing. Three men were killed and 11 cars were wrecked. A passenger train had crossed the bridge only a few minutes before.

◆

AN EXPLOSION OF DYNAMITE occurred, Oct. 26, at the works of the Acme Powder Co., near Pittsburg, Pa., and two men were killed. It is said that 1,000 lbs. of dynamite exploded in the packing house.

◆

A BIG QUARRY BLAST WAS FIRED at the Long Cove quarries of Booth Bros., in Maine, Oct. 23. About nine tons of powder were used and 500,000 tons of rock were lifted and split up. A shaft had been sunk 64 ft. deep, and two tunnels were run from this, with a cross tunnel at each end.

◆

THE RESPONSIBILITY FOR THE BUILDING ACCIDENT at 1078 Madison Ave., on Sept. 26, has been placed by the coroner's jury on Frederick H. Hawkins, who superintended the construction of the building; on Anton D'Andrea, the stone mason, who built the foundation walls; and on the Building Department. The jury recognized the difficulties under which the department labors, and added the following rider to the verdict:

> We hold responsible the Department of Buildings of the city of New York for insufficient inspection. We deplore that a lack of finances tie the hands of the Department of Buildings, while the law calls upon it to perform inspections, which, under the present conditions, are practically a physical impossibility to the available force.

◆

THE EXCESSIVE COST OF ELECTRIC STREET lighting in New York is explained, as follows, by the Commissioner of Public Works: The subways, though under the control of the city, are owned by a private corporation charging rentals. Under the terms of the contract the city can place its police, fire and other wires in these subways free of charge; but the electric light companies pay $1,000 per mile per year for the use of these subways, and must contract for five years, though their contract with the city for street lighting is limited to one year by statute. In some parts of the city, the lighting companies cannot afford to extend their system under the terms imposed. In Boston, 2,000 c. p. arc-lights are furnished for $124 to $127 per light per year, and in Philadelphia the cost is $128. In New York, a 1,200 c. p. light costs from $146 to $182 per year. The Commissioner of Public Works recommends legislation enabling the Gas Commission to extend the time of its contracts, and he further believes that companies should be allowed to use subways free of charge, where such subways were employed exclusively for street lighting.

◆

PAVING BLOCKS MADE OF MEADOW GRASS, says the Atlantic City "Union," are now being made in that city. The inventor is Rev. J. H. Amies, a resident of Atlantic City, N. J., and the meadow grass, impregnated with oil, tar and resin, is pressed into blocks measuring 14 × 21 × 6 ins., and then bound with iron straps. These blocks are said to weigh 40 lbs. per cu. ft., and can be made denser if desired. The claim is made that the street pavement of these blocks is noiseless and elastic, resists wear well and is impervious to heat and cold. Its manufacturers guarantee its life for five years. A plant was erected in Norfolk, Va., about three years ago and experiments were made with the pavement in Norfolk and Richmond and the results are claimed to have been very successful. The grass used is the ordinary wiry salt meadow grass, common along the Atlantic coast.

◆

FIFTH AVENUE, NEW YORK, carries the largest traffic of any street in the United States, says the Commissioner of Public Works of that city. This traffic is greatest between 28th and 42d Streets, where 6,272 vehicles, loading 10,165 tons, pass daily. Broad Street, Philadelphia, in front of the Pennslyvania railway station, comes next in daily traffic, according to Commissioner Collis. The better water supply of the down-town district has necessitated the laying of two 48-in. mains on this avenue, and this work is now in progress. Sewers are also wanting on parts of this highway and these gaps are now being filled up. The fact that Fifth Avenue has been torn up is taken advantage of to replace the stone block pavement with asphalt, from Washington Square to Central Park. This paving is authorized under the appropriation of $1,000,000 for laying the water mains which also provides for repaving the trenches; the repaving over the new sewers is paid for by the property-owners and the balance comes from the annual appropriation for new paving. The asphalt pavement is to have a crown of only 4½ ins. instead of the 7 and 8 ins. of the old stone pavement.

◆

THE NEW YORK CANAL IMPROVEMENTS, authorized under the late $9,000,000 appropriation for this purpose, are reported upon as follows by Mr. A. R. Smith, Secretary of the Executive Canal Committee: With the funds at the disposal of the state three modern double-length steel lift-locks will be built at Cohoes, Lockport and Little Falls, and it is not yet decided whether there will be, at Newark, one double-length steel lift-lock, or two double-length ordinary locks, in place of the present three single-length locks. The Erie Canal will be 9 ft. deep throughout, instead of only in the prism of the canal, as contemplated in the bill, and the depth of 9 ft. will be obtained over all existing permanent structures, allowing boats to load to 8 ft. instead of to 7 ft., as in the bill. These provisions allow for boats 115 ft. long and carrying 60% more load than at present, with a full foot of water under their keels. The amount of money now available is $4,000,000, and power to issue the remaining $5,000,000 in bonds is to be asked from the next legislature. The canals to be improved include the Erie, Oswego and Champlain main canals, aggregating 640 miles of navigable canal, 84 miles of navigable feeders, 261 locks, 33 aqueducts, and 1,100 bridges and other structures. For this work over 1,000 surveys, with maps and blue-prints, have been already made. The work to be undertaken immediately is as follows: Oswego Canal—Raising the Phoenix, Braddock, Minetto, High and Oswego dams about 29 ins. each; the improvement of the Ontario Level, and the lengthening of Lock 18, at a total estimated cost of $159,000. Champlain Canal—Excavation and improvement between Lock 5 and the Waterford side cut; between Locks 6 and 7, and the level between Fort Edward and Fort Ann; at a total estimated cost of $409,758. Erie Canal; Western Division—Excavation, largely through solid rock, at Buffalo and Lockport, and the rebuilding of the Cartersville waste-weir; estimated cost, $1,023,856. Middle Division—From Oneida County line to Lock 51, and lowering of the bottoms of Locks 46, 49 and 50; total estimated cost, $780,973. Eastern Division—Improvements costing $744,099. The total estimated expenditure on the above canals, as given, amounts to $3,117,692. The total probable quantities, as given upon the bidding sheets, are as follows for the principal items: Total excavation, 3,261,077 cu. yds total iron and steel, 1,725,491 lbs.; lumber, 6,475,520 ft. B. M.; 33,855 cu. yds. concrete; wall masonry, 235,150 cu. yds.; lining, 158,930 cu. yds.; channeling, 263,150 cu. yds.; embankment, 209,540 cu. yds.; puddling, 26,265 cu yds.; piling, 104,265 lin. ft.

◆

A BRICK CHIMNEY IS BEING MOVED about 1,000 ft., at Bridgehampton, L. I. This chimney is 75 ft. high and weighs about 100 tons; it belonged to a hotel destroyed by fire and is to form part of a newly built structure. The contractors for the work are William and Charles P. Topping, of that place.

STRUCTURES ON THE SAN FRANCISCO & SAN JOAQUIN VALLEY RY.

(With inset.)

The line of the San Francisco & San Joaquin Valley Ry., which is now under construction, will extend from Stockton, Cal., to Fresno, and Bakersfield, a distance of about 250 miles, and is already completed as far as Fresno, while at Stockton there is connection with river steamers for San Francisco. The first train entered Fresno on Oct. 5. The railway parallels some of the lines of the Southern Pacific Ry., having one of that rival's lines on each side (about 12 miles away), nearly all the way to Fresno, but it is to open up a large local traffic in the wheat and fruit growing district of the San Joaquin Valley. Mr. Claus Spreckels is at the head of the enterprise. Mr. Wm. B. Storey, Jr., M. Am. Soc. C. E., is Chief Engineer, and during a visit to San Francisco last summer we obtained from Mr. Storey the blueprints, photographs and information made use of in the preparation of this article.

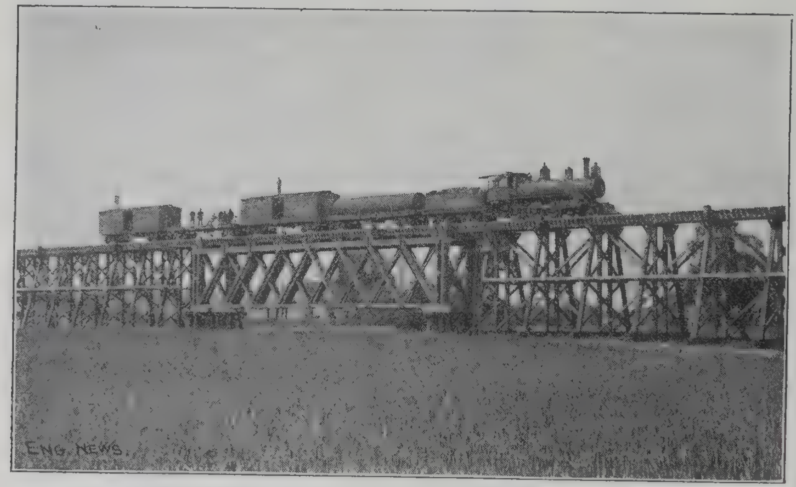

FIG. 1.—BRIDGE & TRESTLE ACROSS DRY CREEK; S. F. & S. J. V. RY.

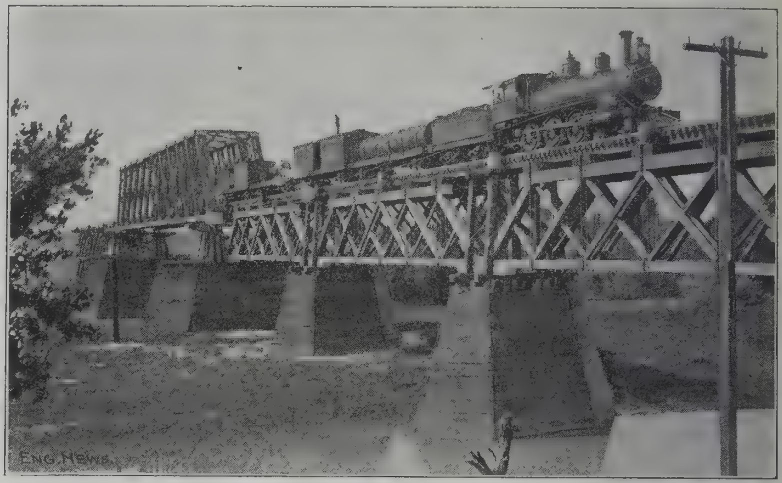

FIG. 2.—BRIDGE ACROSS STANISLAUS RIVER; S. F. & S. J. V. RY.

The railway traverses a fairly level country, and has easy grades, the maximum grades being 0.3%. The earthwork is mainly adobe soil and hardpan, the latter requiring a considerable amount of powder to break it up. Grant Bros., of Los Angeles, and San Francisco, were the contractors for the grading.

The generally flat country of the valley is intersected by a number of deep, wide ravines, or river channels, which necessitate a considerable amount of bridge and trestle work. These structures are mainly of Oregon pine. All the bridges were designed by and all bridge material was purchased by the chief engineer of the road, the contract for the work of erection being let to the San Francisco Bridge Co.

Fig. 1 shows the bridge and trestle across Dry Creek, and represents the general type of trestle approach to the bridge spans. In this particular case the right hand bank falls away sharply at the pile abutment to the level of the stream crossed by the Howe truss deck span. The trestles have four-post bents of squared timber, and a noticeable and commendable feature in the design is the ample provision of transverse and longitudinal diagonal bracing, the latter bracing being far too often omitted in structures of this kind, leaving the stringers and the waling-pieces to carry all the longitudinal strains. Fig. 2 is a view of the bridge over the Stanislaus River, having one through truss channel span, and deck trusses for the approach. The piers are of pile clusters, sheathed with timber to protect them from floating driftwood, etc.

Fig. 3 (on the inset sheet) gives the details of the construction of one of the three 150-ft. Howe truss deck spans over the San Joaquin River. The lower chord is continuous over the three spans, the upper chord is broken over each pier. The panel length is 12 ft. 6 ins., and the truss depth (between chords) is 20 ft. The truss rods pass through tubes or sleeves in the chords, and the joints in the lower chord-members are spliced by eyebars. The truss has a camber of 3 ins., 2 ins. of which are taken out by sizing the ties over the stringers, and 1 in. of camber is left in the track. At each panel point are the floor timbers 6 × 18 ins. and 8 × 18 ins., 20 ft. long, carrying track stringers 6 × 14 ins., on which again are the ties, 8 × 8 ins., 8 × 9 ins. and 8 × 10 ins., 9 ft long. There are inside guard rails of the same weight as the track rails and set 8 ins. clear from them, while the guard timbers 6 × 8 ins. (set flat) are on the outside, 8 ins. from the track rails. The guard timbers are bolted through tie and stringer at every fourth tie, these ties being boxed out 1 in. for the guard timbers, while at the other ties the guard timbers are boxed out 1 in. A horizontal lateral bracing connects the upper chords and the lower chords, while at each panel point is a vertical diagonal sway bracing, the pieces of which (in the larger sizes) are boxed out ½-in. at their intersection.

The combination passenger and freight stations of this railway are of simple and attractive design, and conveniently arranged, as will be seen by the plans and elevations in Fig. 4 (on the inset sheet). On the ground floor, all under one roof, are an open waiting room, a closed waiting-room and an agent's office and storeroom; then comes a baggage-room and then a large freight room, the latter having a raised platform on three sides. The middle part of the building is carried up to form a second floor with living accommodation for the station agent.

The track is laid with rails weighing 62½ lbs. per yd., rolled by the Bethlehem Iron Co. and the Homestead works of the Carnegie Steel Co. They are of the Am. Soc. C. E. section, the dimensions being a mean between those of the 60-lb. and 65-lb. recommended sections. There are 16 redwood ties to a rail length of 30 ft., with Servis tie-plates on every tie. The rails are laid with suspended broken joints, spliced by angle bars and four bolts. The ballast is of gravel. The switches and frogs were designed in the chief engineer's office and built by the Pacific Rolling Mills and other coast works, being a new class of manufacture in that part of the country. The engines were built by the Baldwin Locomotive Works, of Philadelphia, Pa., and the cars by W. L. Holman, of San Francisco, Cal., and the Ensign Car Mfg. Co., of Huntington, W. Va.

◆

MODERN OVERHEAD CONSTRUCTION FOR ELECTRIC RAILWAYS.*

By Benjamin Willard.

The steel pole presents a neat appearance, and takes up a small amount of space. The insulating qualities are not as good as with the wood pole. As to its lasting qualities, I have made some observations on wrought iron columns that have been in the ground for several years, and I am convinced that in a moist climate a limit on the practical life of such poles would not be over 30 years. I believe that from a practical and financial standpoint, wood poles should be used in many instances.

Through the business sections of cities steel poles are in some respects better, as they cannot be either wilfully or accidentally mutilated. In suburban or residential districts the wood poles when properly dimensioned answer every purpose, and look fully as well as the steel poles. A heart pine or cedar pole will, if properly selected and kept painted, last in some climates 20 years. This is a known fact from observation of poles that are now in sound condition after having been erected for that length of time.

Suppose we select New Orleans as a suitable location to build a road and base our estimates on cost of material there. The cost of steel poles would be greater than in many northern cities owing to freight rates and distance from the manufacturers of such poles. Wood poles can be furnished for less in New Orleans owing to their near production, so that I think an estimate covering the cost at that point would be a fitting proposition elsewhere.

The following are estimates for cost of construction in New Orleans, where steel poles cost more and wooden poles less than in Northern cities. For one mile of span wire construction 104 steel poles, at $15 each, would cost $1,560, and assuming their life to be 30 years, the interest on the investment for 30 years at 5% per annum would be $2,340, or a total first cost and interest of $3,900. The setting of steel poles necessitates the use of concrete. I estimate the cost of this and the labor of placing it at $4.50 per pole, or $468 per mile, which, with interest for 30 years at 5% per annum, would be $1,170, or a total for interest and first cost of material and labor of $5,070 for the steel poles.

Assuming the life of heart pine poles to be 12 years (instead of 20 years) I will make a comparison on that basis. Such poles for one mile of span wire construction at 104 poles to the mile at $4.50 each would cost $408; labor and material for erecting at $2.50 per pole, $260, or a total first cost of $728; to this must be added interest for 30 years at 5% per annum, $1,092, making the first investment at the end of 30 years $1,820. At the expiration of 12 years the construction must be renewed at a cost of $728, and to this must be added interest for 18 years at 5% per annum, $655.20, making the second investment at the end of 30 years cost $1,383.20.

At the expiration of 24 years the construction will be renewed for the third time at a cost of $728, and to this will be added the interest for six years at 5% per annum, $218.40, making the third investment at the end of 30 years cost $946.40, a grand total for wood pole construction of $4,149.60. The difference between the total costs of steel and wood pole construction for a period of 30 years would be $920.40 per mile, which would be more than a liberal allowance for changing span wires and other work necessary in renewing the wood poles, but assuming it would take this amount we would stand even at the end of 30 years and still have six years more life in the wood pole construction.

If steel span poles are used I would recommend for the average span of 40 ft. a pole weighing about 700 lbs., made in two parts. The lower section to be constructed of 6-in. extra heavy standard steel pipe and the upper section of 5-in., swaged at the joint for a distance of 18 ins. Such a pole should be 28 ft. long, 18 ft. for the lower and 10 ft. for the upper section, and provided with a cast-iron and wood pole top for the attachment of the span wires. There should be a wood filling to fit the bottom of the lower half to prevent it from sinking, and the pole should be set 6 ft. in the ground with a rake of 10 ins. from the perpendicular to allow for being straightened when under strain. The average size of hole to be dug would be 20 ins. in diameter with a depth of a little over 6 ft., requiring (after the pole is inserted) a

mixture of about ½ cu. yd. of 1, 2 and 4 Portland cement concrete. The cement should be set at least three days before attaching the span wires. Whenever it is practicable, allow poles to bear against the curbing, as it affords an efficient stay for the pole. Otherwise a good-sized rock having a bearing surface of about 1 sq. ft. would assist very much, and keep the pressure from cracking the cement.

If wood poles are used where it is necessary to provide neat and substantial construction, I would recommend for the average span of 40 ft. a long leaf yellow pine pole dressed and chamfered, 30 ft. long, sawed square, 11 × 11 ins. at the base, and 7 × 7 ins. at the point, free from sap, rot or knots, and corners evenly chamfered, 1½ ins., beginning at a point 14 ft. from the base, and terminating in an octagonal form and roofed evenly for a space of 3 ins.

In setting wood poles where concrete is not used (and I do not consider it necessary) a great deal depends upon the soil encountered. In a soil of medium clay, and average condition, poles should be set 6 ft. in the ground with a rake of 12 ins. from the perpendicular, and the hole should be dug to a vertical depth of 6 ft. (or more if necessary to allow the pole to stand a given height above the track) and should be about 2 ft. square at the top and not less than 18 ins. at the bottom. Where it is practicable allow poles to bear against the curbing (or paving). Place a substantial bearing at the heel to prevent the pole from pressing through the earth; for this purpose a small quantity of coarse broken stone or brick bats will answer every purpose. Where this is not easily obtainable, and the earth is soft, a piece of plank 12 ins. wide by 3 ins. thick, 4 ft. long, sharpened and driven in the earth to a depth of about 2 ft. at the back and base of the pole will give good results.

Whenever it is necessary to erect poles in the absence of substantial material at the surface, such as paving or curbing, I would recommend that the base of the pole be well rammed with broken rock for a distance of 18 ins., taking pains that the greater quantity is placed at the back where the pressure is greatest and leaving a small quantity in front where no pressure takes place. The space to within 20 ins. of the top may be filled with earth taken from the hole and well rammed. To prevent the pole from yielding at the surface a breast plank of oak (or cypress) timber 3 × 12 ins. × 6 ft. should be placed and spiked in front and at right angles to the pole about 8 ins. under the surface of the ground. About 20 ins. from the top of the hole and in front of the breast plank should be filled and well rammed with the same material that is used at the base of the pole. The necessary quantity of broken rock required would be about 1-5 cu. yd. per pole.

Poles of wood or steel which may be used for holding strains at curves should necessarily be heavier than those used for straight line construction, and should also be set at greater depth in the ground. A steel pole for curve construction should be 29 ft. long, made of 6-in. and 7-in. extra heavy pipe, the larger section to be 19 ft. long and the smaller section to be 10 ft. long and made to weigh 1,050 lbs. Such poles should be set 7 ft. in the ground, and raked 10 ins. from the perpendicular in a direction radiating from central point of curve where strain is required. The filling would be the same as specified for straight line iron pole construction.

Wood poles for curve construction would be made similar to those specified heretofore for straight line construction, excepting dimensions of such poles should be 31 ft. long by 14 × 14 ins. at the butt, 9 × 9 ins. at the top. Such poles should be set 7 ft. in the ground and raked 12 ins. from the perpendicular in a direction radiating from the center of curvature where strain is required. The hole should then be entirely filled with about 7-10 cu. yd. of broken rock well rammed.

The holes for eye-bolts should be bored in wood poles before their erection and the bolt should incline slightly downward towards the eye to prevent the water from following in and rotting the top of the pole. The correct location for eyebolt holes would be determined by the height at which the trolley wire is to be placed, 22 ft. from the base of the pole would be correct, assuming that we allow 2 ft. for drop in the earbody and ear, and also dip in the span wire would make the height of trolley wire about 20 ft. To facilitate the setting of poles to a uniform height it is a good plan to place grade stakes near the location selected for poles indicating a given height relative to the grade of the track.

Center pole constuction is required in many locations, but I consider span construction better owing to its flexibility and for being less unsightly. There are now on the market appliances for making bracket suspensions flexible, which are an improvement over the old type of rigid construction. One of the most practical which I am familiar with is an attachment to receive a short span of flexible wire and the ordinary straight line hangers.

Poles used for center and bracket construction should be made according to the same specifications as those used for span construction, excepting that an ornamental pole top would be required for the steel pole instead of an insulated one. For the bracket arm a 1½-in. pipe of the required length attached to a malleable iron collar made in halves and encircling the pole and supported by truss rods leading from the end and center of the arm to near the top makes an excellent and neat construction.

Wherever guard wires are required it will be necessary to leave about 2 ft. additional space on the top of the pole above where the trolley span wires are attached for the attachment of the guard wire span. It would hardly be practical to provide an insulated pole top for both span wires, so the trolley span would be supported by means of a wrought iron clamp collar encircling the pole at the proper point and provided with suitable insulating fastenings. I do not especially approve of this method of construction (as I do not favor guard wires), but I would recommend it where it is compulsory to erect guard wires.

All poles should be painted with one coat before their erection, as it affords better opportunities to carefully apply the priming coat and at less expense than after the poles are set. A paint of dark green composed of graphite mixture I find to wear well, and although it costs more than some other paints, it has better lasting qualities (especially in iron work). A second coat of this paint after the poles are erected will cover marred places made necessary in setting, and will look well and last for at least two years.

Span Wires.—Span wires should be of flexible steel, 5-16 in. in diameter, composed of seven strands of No. 12 galvanized wire, and when under strain with conditions of pole setting as above would have a tension of about 750 lbs. when erected. Whereas I have allowed 18 ins. for sag in the span, it probably would not be over 12 ins. at the time the wire is first suspended, but it will gradually sag more as the wire stretches and the poles spring or yield in the ground, so if a 40-ft. span is attached 22 ft. above the rail surface, the trolley wire within the course of a year would measure aproximately 20 ft. above the rail.

Where wood poles are used (or wood pole tops for steel poles) the ordinary ⅝ × 12-in eye-bolt, threaded about 4 ins., answers every purpose for the attachment of the span wires, and other devices more expensive which are used for the same purpose are not necessary. Poles when properly set will bear a given strain on the span wires for many years without much yielding, consequently an adjustable device is rarely, if ever, used. Hard drawn copper trolley wire of No. 0 B. & S. gage has been found to be the most practical dimension of wire and is generally considered a standard for most trolley construction; therefore, overhead appliances are made of various manufacture to meet such requirements. There has been a trolley wire recently manufactured of a figure 8 section which is now in use on some roads and has given very good results. Where this wire is used it leaves a perfectly unobstructed surface for the trolley wheel and gives greater current carrying capacity, but in modern construction the hanging appliances have reached such a degree of perfection that the round wire can be used with equally as good results, and as the trolley wires on large systems are relied upon but little as a conductor for current capacity, I can hardly recommend anything that would be more practical than the round wire.

The best forms of span wire hangers and insulators are those in which the insulation is concealed from the weather as much as possible, and with a metallic covering to prevent them from being broken by accidental contact of the trolley pole. Brass hangers are more expensive than iron, but resist the moisture and are maintained at much less expense. Iron hangers if kept in good condition should be painted at least once a year, as the oxidization if allowed to accumulate will form a conductor between the conductors and span wires, and in course of time will cause the escape of current by leakage. Hard rubber insulation for hangers is more expensive than many other compositions, but it has fine insulating qualities, and stands different conditions of climate with little or no deterioration.

Suspension ears are of as many varieties as hangers. I have had experience with many, and have concluded that a little modification of the old brass solder ear is the most practical and lasting of all, if properly attached. A solder ear should be 15 ins. in length tapped for a ⅝-in. cap bolt and provided with thin lips at either end so dimensioned as to encircle but little more than half the trolley wire. One point which should be observed very particularly is to have the ends of the ears ground to a thin tapering end so that they will be flexible with the vibrations of the wire. If the ends are made heavy or unyielding, the vibrations will have a tendency to detach the ear at the points, and when this takes place it is a question of a short time before the ear is wholly detached.

For curve construction I favor what is known as the goose-neck hanger, which is simply a ⅝-in. steel forging of such dimensions as to allow good clearance for the trolley wheel and fastened to the soldered ear in a manner to permit it to swivel, also provided with an eye for the attachment of pull-over wires. Such devices are strong, and do not present an obstructive object for the trolley to catch in. There is no insulation attached to such ears and this is the only thing in their disfavor, but as there are many insulating devices to overcome this difficulty which can be attached to the hanger, this could be considered a minor point.

There is a wide difference of opinion relative to the arrangement of sections and the methods of feeding the sections of the trolley wire. In many installations a practice is made of leading each individual section feeder to the station and separating the trolley into sections by sectional insulations, making it possible to cut out the various sections at the power-house. This is a convenience in that it makes every section of the line directly controllable from the power plant. Another method is to have every feeder on the whole line doing a share of work at all times, whether the cars be assembled on one section or distributed over the entire line. This, of course, can only be done by means of connections representing the whole line as being in one general section, making short sections controllable by external switches. In the first method mentioned an accumulation of cars may be assembled on one section not estimated for carrying an abnormal load, consequently the feeder would be overtaxed on this particular section, whereas the feeders on other sections would be doing little or no work. Consequently, there would be a difference of potential between the adjoining sections. If there is a bridge around each section insulator connecting each section together and connected by a feed wire so that the current will equalize itself between two sections and will distribute itself from all feeders, then we have a small amount of variation of potential from section to section, and every feeder is auxiliary to every other.

To carry out this method of uniting the trolley sections the line is divided into sections by means of sectional insulators. A switch box is placed on the pole (at a convenient height) in which is contained two switches and fuses, one for the section on either side of the sectional insulator; the feeder is then divided by connection through each switch so that the feed wire delivers current to either section through feeder span wires attached to connections on each side of the sectional insulator. When the entire line is in operation there is an equalization of current in all sections, and the trolley remains virtually as a solid conductor, but with all necessary features for disconnecting the sections.

In most localities where a large system of feed wire distribution is required it is necessary to erect special construction for that purpose. The most economical plan is to select centers of distribution reached by the most direct routes from the power station and establish at such points what may be called junction poles to which are attached the heavy trunk line feeders leading from the power plant, and smaller feeders for distribution to the trolley line. By this plan we may erect wires of 500,000 or more circular mils. capacity from the plant to the junction pole, and attach them to a junction frame or frames attached to the pole which is provided with a bus-bar of sufficient carrying capacity to carry the current of the branch feeders. The large cables are dead-ended in the junction frame by eye-bolts and strain insulators, and copper connections are made with the bus-bar. The branch feeders are ended and connected in the same way so that it is possible with little delay to cut out any feeder and make changes which are often necessary in operation.

Southern pine cross arms, 5 × 3½-ins., bored to receive 1½-in. pins and doubled on each pole will make sufficiently strong construction to receive the heaviest wires. The pins should be of locust-wood, bored to receive a ½-in. bolt, which should extend verticallly through the center of the pin and terminate with a washer and nut on the under side of the arm.

Top grooved glass insulators are desirable in all classes of heavy feed wire construction. Feed wire conductors of larger area than 0000 B. & S. gage should be in stranded, or in cable form, triple insulated with the best waterproof covering. Care should be taken in splicing cables that an even strain is brought on each smaller wire and that none are allowed to remain without good contact, and that all flux used in soldering is carefully removed before tapeing.

THE STONE INDUSTRY OF THE UNITED STATES IN 1894 AND 1895.

The Department of the Interior has issued a report upon "The Stone Industry in 1895," prepared by Mr. William C. Day, of the U. S. Geological Survey. From it the following extracts are made: The values of the several kinds of stone produced in the two years are set down as follows:

Kind.	1894.	1895.
Granite	$10,029,156	$8,894,328
Marble	3,199,585	2,825,719
Slate	2,790,324	2,698,700
Sandstone	3,945,847	4,211,314
Limestone	16,190,118	15,308,755
Bluestone	900,000	750,000
Totals	$37,055,030	$34,688,816

Divided by states, Pennsylvania ranks first with a product, chiefly limestone, worth $5,563,451; Vermont marble and granite was worth $3,254,647 in almost equal amounts; Ohio limestone and sandstone was valued at $3,018,372; Maine's product was worth $2,240,154, mainly granite, and Massachusetts produced $2,335,381 worth of stone, almost all granite. After these states come New York, Indiana, Illinois, Connecticut, Georgia and Missouri, in the order named, with products valued at more than $1,000,000 and less than $2,000,000; although 39 states in all contribute something to this industry. The total value of granite paving blocks made in 1895 was $1,773,328; Maine and Massachusetts contributing $1,132,607 of this amount. In 1894 the value of paving blocks produced was $2,254,587. The granite output of the United States shows a steady decline from $14,464,095 in 1890, to $8,894,328 in 1895; with the exception of the gain noted for 1894 over the $8,808,934 of 1893. The marble product shows a gain from 1890 to 1893, a maximum in 1894 and a decline in 1895. The total of roofing slate for 1895 was 729,927 squares valued at $2,351,509, as compared with 738,222 squares valued, in 1894, at $2,301,138; the price, however, has increased from $3.11 to $3.23 in 1895. The sandstone industry shows a slight improvement in general condition; though the value of this product in 1890 was $10,816,057. The value of the lime output, in 1895, was $6,595,122 as compared with $8,610,607 for the preceding year, a falling-off nearly sufficient in itself to account for the total decrease in the value of the industry as compared with 1894. But the decrease in lime burned was offset by an increase of more than half a million in the limestone used for fluxing in 1895 in Alabama, Colorado, Montana, Ohio and Pennsylvania. The bluestone output is estimated for both 1894 and 1895, and the report enters into no details of this industry.

SPIRAL CURVES FOR STREET RAILWAYS.*

By Chas. A. Alden, C. E.**

The use of the railway spiral as an entrance to street railway curves, has not been as extended as it should have been, owing to the lack of suitable tables for its use.

While many variations of its form might be made, it is believed that the following tables will meet most cases arising in usual practice.

Table I. gives a choice of 50 spirals for curves of radii from 30 ft. to 1,785 ft. In case a special spiral is desired for any reason, these may be modified by multiplying by a suitable factor, in the same way that spirals No. 1 and No. 2 have been obtained from spirals No. 4 and No. 5.

Spiral No. 3 was designed as the spiral of shortest length to enable a certain double-truck car to pass on a double-track curve. Branch-off Easement No. 2 was designed in the same manner.

While the car used for this purpose was one of the largest double-truck cars in use, on surface roads, in the East; this should be carefully tried with the car in use on the road in question, as, indeed, it must necessarily be, in order to select a radius for the outer curve.

Substantially the same chord length was carried throughout the system with a view to ease in giving the necessary information to the track-layers.

At switches it is mechanically undesirable to have a greater initial radius than 100 ft. This will prevent the use of a true spiral at these points, but Table II. gives a set of arbitrary easements which conform as nearly as possible to the theory of the spiral; i. e., they have a constant increase or decrease of angle in each length of arc after leaving the switch.

Office Work.—The most satisfactory way of plotting these curves is to cut out thin celluloid templates of each one which is to be used. Mark each P. C. C. of the spiral on the curved edge and the direction of a radial line through this point.

Problems No. 3 and No. 4 can generally be solved accurately enough on a drawing made to scale and in less time than by calculation for "special work" curves, as a plan must be made in any event, in order to have the work made by the manufacturer.

If only a few curves are to be drawn up, however it may be more expeditious to figure the curve and plot the points on the spiral by the x and y taken from the table, and connect them with a variable or "French" curve.

Field Work.—The problems which are solved below give all the rules necessary for laying out nearly any curve with symmetrical spirals. In the appendix is given the solution for the most common form of non-symmetrical curve.

It is by no means necessary to lay out on the ground every point on the spiral. If the curve is "special work" and curved by the manufacturer, the point of spiral, a point about in the centre of the spiral and the junction of the spiral with the main curve should be laid out.

Points for the latter should be laid out from 20 to 30 ft. apart, depending on the radius of the curve and the location of the joints.

If the curve is to be "sprung in" by the track-layers, every alternate point on the spiral should be laid out and the track-layer furnished with sufficient middle ordinates for 10-ft. chords.

These can be obtained by Problems 9 and 10 and Table III.

The most expeditious way to lay out a spiral curve, if the "x" does not exceed 2 ft., is to set the transit on the intersection point and lay off the tangent distances, then lay out sufficient points on the spirals by the successive offsets x and the long chords. Then bisect the included angle and lay out a temporary point v; Problem 8.

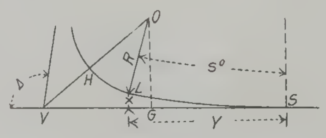
Move the transit to the last point on the spiral, set the vernier to a back reading equal to the spiral angle. Set the telescope on an offset from v equal to x inside of the intersection point. Deflect to 0° and the line of the telescope should strike v′ and the distance $v' L = R \tan(\frac{1}{2} \nabla - s°)$. This will check the preceding calculations and field work. The circular arc can then be laid out in the usual manner.

Problem No. 1.—To Select a Spiral.—(a). The radius of the main curve must be less than the preceding branch of the spiral; must be more than the next branch would be, were it produced; and should nearly equal the latter.

Note.—Easements No. 3 and No. 4, Table II. For greater, read less; and for less, read greater.

(b). The longer the spiral, the easier the entrance will be. But bear in mind that the main body of the curve should be circular, the spiral simply acting as an entrance to it.

(c). A spiral of less than three branches should not be used.



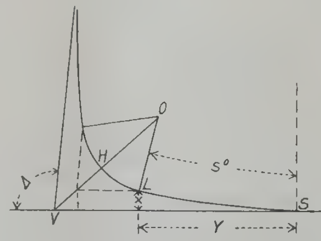
Problem No. 2.—Given: A circular curve with symmetrical spirals, to find the tangent and external distances.

$$O G = R + x - \text{ver. sine } s° R.$$

$$G S = y - \text{sine } s° R.$$

Tangent distance $= O G \tan \frac{1}{2} \triangle + G S$.

External distance $= O G \text{ ex. sec. } \frac{1}{2} \triangle + x - \text{ver. sine } s° R$.



Problem No. 3.—Given: The tangent distance vs. the intersection angle △, and the desired length of spiral to find the radius of the curve.—Approximate R = cotangent ½ △ (vs. — ½ length of spiral.)

Having selected a spiral by this radius, the exact radius may be found, if required, by the following formula:

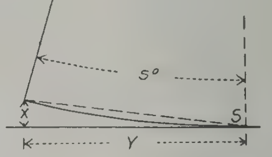
$$R = \frac{\cos. \frac{1}{2} \triangle (v s - y - x \tan \frac{1}{2} \triangle)}{\text{sine } (\frac{1}{2} \triangle - 5)}$$

Caution: If the result is enough different from the original radius to require a change in the spiral by Problem No. 1 (a), a second trial must be made. This rule does not apply for approximate radius to the easements in Table II.

Problem No. 4.—Given: The intersection angle △ and the external distance VH; to find the radius.—Approximate to the radius by finding that for a simple curve passing through the point H, and select a spiral for a radius somewhat smaller. Then

$$R = \frac{V H \cos. \frac{1}{2} \triangle - x.}{\cos. s° - \cos. \frac{1}{2} \triangle.} \text{ (Searle.)}$$

Caution: If the result is enough different from the original radius to require a change in the spiral by Problem No. 1 (a), a second trial must be made.



Problem No. 5.—Given: The x and y for any point on the spiral; to find the deflection from the tangent at the point of spiral.

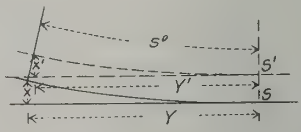
$$\text{Tan. deflection } ° = \frac{x}{y}.$$

Problem No. 6.—Given: The x and y for any point on the spiral; to find the long chord.

(a). $\text{Long chord} = \frac{Y}{\text{cosine def. angle}}.$

or

(b). $\text{Long chord} = \sqrt{x^2 + y^2}.$

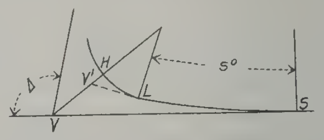


Problem No. 7.—Given: x and y for a point on the spiral; to find x′ and y′ on a line paralel to the spiral, and offsetted the distance ss′ inside the spiral.

$$x' = x - s s' \text{ ver. sine } s°.$$

$$y' = y - s s' \text{ sine } s°.$$

Note.—Problems Nos. 5 and 6 can then be applied to x′ and y′ if it is desired to use deflection angles to lay out the curve. As these curves will almost invariably be laid out on an offset, varying with the gage of the road; the deflections are not figured in the table.

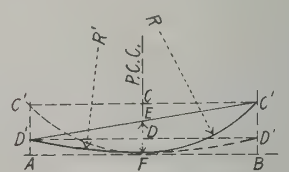


Problem No. 8.—Given: A circular curve with spirals; to find the distance VV′, in order to lay out a tangent to the circular curve, from which the latter may be laid out in the usual manner.—

$$V H = \text{see Problem No. 2.}$$

$$V' = R \text{ ex. secant } (\tfrac{1}{2} \triangle - s).$$

$$V V' = V H - V' H.$$

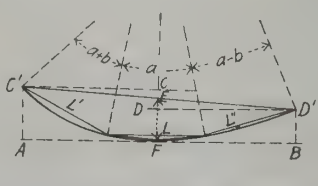


Problem No. 9.—Given: The middle ordinate for a chord of length AB for R and R′; to find the middle ordinate at the P. C. C. From the figure it is evident that

$$D' C' \text{ bisects } C D \therefore E F = \frac{C F + D F}{2}.$$

Therefore, the middle ordinate at any P. C. C. in the spiral equals ½ the sum of the middle ordinates for the radii on each side for the same chord.

Note.—See remark following Problem No. 10.



Problem No. 10.—Given: That portion of a spiral with equal chords L, L′ and L″ and angles a—b, a and a+b; to find the middle ordinate at the centre of the chord L in the length D'C'; CF = C' A and DF = D'B. From the figure it is evident

---

*Copyrighted, 1896, by Chas. A. Alden.

**Principal Assistant Engineer, Street Railway Department, Pennsylvania Steel Co.

$$\text{that } D'C' \text{ bisects } CD, \therefore EF = \frac{CF + DF}{2}.$$

Then

$$C'A = \tfrac{1}{2} L \tan \tfrac{1}{4} a + L' \text{ sine}\left(\tfrac{1}{2} a + \frac{a+b}{2}.\right)$$

$$D'B = \tfrac{1}{2} L \tan \tfrac{1}{4} a + L'' \text{ sine}\left(\tfrac{1}{2} a + \frac{a-b}{2}.\right)$$

and since the sines of small angles are proportional to the angles;

$$\frac{CF + DF}{2} = EF = \tfrac{1}{2} L \tan \tfrac{1}{4} a + L \text{ sine } a.$$

But this last equation equals the middle ordinate in the length AB for the radius of the central arc; and since the increment to the angle, b, would be equal if L' and L'' were equal; the middle ordinate at the centre of any arc of the spiral, for any length of chord; is equal to the middle ordinate of the radius of that arc in the same length.

Remark: It will be noticed that the solutions of Problems No. 9 and No. 10 are slightly inaccurate in not allowing for the increase of length of D'C' over AB, nor for the inclination of the middle ordinate found to the true middle ordinate.

Problem No. 10, if applied to the curving of rails, as intended, also assumes that each rail forms a spiral, whereas they are simply parallel lines to one.

Both solutions, however, are sufficiently accurate for any spiral of 5 ft. chords or greater.

Taken in connection with Table III. the m. o's can be easily found for points on the rails from 2½ ft. to 3 ft. apart. The rails being curved to these, exactly what is desired will be obtained, i. e., a curve of constantly changing radius, which is considered a compound curve for the purpose of calculation only.

These spirals are figured for a length suitable to the ordinary street railway speeds. For greater speeds, the writer would advise the use of the regular railway spirals. Tables in convenient form for these have been published by Wm. H. Searle, C. E., and others.

The tables given herewith have been carefully checked, and no error found as great as 1 in the last place.

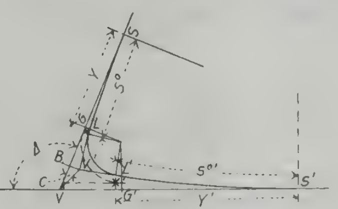
APPENDIX.



General Solution for Unsymmetrical Curves.

$O\,G = R + X - R \text{ ver. sine } S°;$

$G\,S = Y - R \text{ sine } S°;$

$O\,G' = R + X' - R \text{ ver. sine } S°';$

$G'\,S' = Y - R \text{ sine } S°';$

$$V\,S = \text{Tan } \tfrac{1}{2} \Delta\; O\,G + G\,S + \frac{O\,G' - O\,G}{\text{sine}};$$

$$V\,S' = \text{Tan } \tfrac{1}{2} \quad O\,G + G'\,S' \cdot \frac{O\,G' - O\,G}{\text{Tan}}$$

Note— ± in above; + if $\Delta = 90° +$ and − if $\Delta = 90° -$.

$\Delta' = \Delta - (S° + S°');$

$V'\,L \text{ or } V'\,L' = \text{Tan } \tfrac{1}{2} \Delta'\, R;$

$V'\,B = X + V\,L \text{ sine° } S;$

$V\,B = V\,S - (Y + V\,L - V\,L \text{ ver. sine } S°);$

$$\text{Tan } C = \frac{V'\,B}{V\,B}.$$

$$V\,V' = \frac{V\,B}{\text{cosine } C} \text{ if } C < 45° -;$$

$$V\,V' = \frac{V'\,B}{\text{sine } C} \text{ if } C > 45° +;$$

THE ACTUAL ACCURACY OF CHEMICAL ANALYSIS.

The degree of accuracy ordinarily obtained in every-day practice in chemical analysis was discussed by Mr. Frederic P. Dewey in a paper read on May 14, 1896, before the Washington Section of the American Chemical Society ("Jour. Am. Chem. Soc.," Sept., 1896; also "Trans. Am. Inst. M. E.," Denver meeting, Sept., 1896). In May, 1881, Mr William Kent presented a paper to the American Institute of Mining Engineers, entitled "Manganese Determinations in Steel," in which he gave 24 determinations of manganese, by ten different chemists, on samples from a plate of steel. These results presented the remarkable range of from 1.14 to 0.303%. In 1886, Capt. A. E. Hunt ("Trans. Am. Inst. M.E.," vol. XV., p. 104), in giving a measure of the accuracy of the colorimetric method, speaks of a variation of 0.2% in steels containing from 0.15 to 1.5% of Mn. as "sufficiently accurate for all practical work." This degree of accuracy shows a satisfactory advance over the results reported in 1881. In 1883, Mr. G. C. Stone began a series of contributions on "Determinations of Manganese in Spiegel" ("Trans. Am. Inst. M. E.," XI. 323, XII. 295, 514). In his first paper he reported 13 determinations by five chemists, on the same sample, ranging from 15.49 to 13.83, also 26 determinations by ten chemists, on a sample of the same spiegel, ranging from 14.56 to 10.36%, some of the low results being obtained by experimental methods. Of a total of 73 determinations by 19 different chemists, rejecting eleven on account of methods used, or because the chemists were not entirely satisfied with them; there are left 60 determinations by 18 chemists, ranging from 14.47 to 12.60% and averaging 12.60%. Mr. Dewey concludes from a study of Mr. Stone's results that variations of 0.5% in determinations of spiegel of this grade (10 to 15% Mn.), are to be expected, and much wider variations may be found.

In determinations of phosphorus in steel extensive researches have shown that the different chemists using modern methods obtain results which are highly satisfactory. On one sample 36 results obtained by 23 chemists ranged from 0.055 to 0.045%, an extreme variation of only 0.010%. On another sample 38 results ranged from 0.091 to 0.076%, an extreme variation of 0.015%. In determinations of phosphorus in pig iron the results show a wider variation. Mr. F. E. Bachman, in 1882 ("Trans. Am. Inst. M. E."), reported 44 results by 18 chemists, ranging from 0.165 to 0.096%, the extreme variation being 0.069%. Analyses of copper ores show a wide variation, 45 determinations by 17 chemists gave results ranging from 53.34 to 43.92%. On pig copper the results of 17 determinations by seven chemists ranged from 91.07% to 98.17%, but throwing out six of the results which differed widely from the average the remainder range from 94.91 to 94.38, which may be regarded as very good work. Copper mattes determined by electrolysis by eight chemists, gave from 55.17 to 54.50. The total range of 0.67% is regarded as very satisfactory. By the cyanide method six chemists reported results ranging from 54.08 to 50.55%. A plate of copper analyzed by six chemists gave from 98.46 to 97.04% of copper.

In gold and silver assays of copper-material 26 determinations by 20 chemists gave from 164.35 to 148.5 ounces of silver to the ton, and 0.501 to 0.205 ounces of gold to the ton.

A HARBOR OF REFUGE, near the mouth of Delaware Bay, is about to be constructed by the U. S. government. The location was fixed by a board of U. S. Engineers, under the provisions of the River and Harbor Act of 1890, between the Shears Shoal, about three miles off shore from Lewes, Del., and a breakwater to be constructed; the latter about 8,000 ft. long. In order to protect this harbor from ice coming down the Delaware River a row of ten ice-piers will be built across the head of the harbor, about one-half mile above the breakwater. This breakwater will be about two miles from the old Delaware breakwater and almost north of it; constructed of random stone in very large blocks, with a top width of 40 ft., at low-water mark, and a sea-slope of 1 in 3 and a harbor-slope of 1 in 1.35. For 14 ft. above mean low water the blocks will be laid in courses, with a top width of 20 ft. The protected anchorage will include an area of about 800 acres, with a minimum depth of 30 ft. over 552 acres, and a low-water depth of not less than 24 ft. over the remainder. The total estimated cost is about $4,600,000, divided as follows: Breakwater complete, $3,863,373; ten ice-piers, $377,500; engineering and contingencies, $424,127. The board fixing upon the location was made up of Gen. Wm. P. Craighill, now Chief of Engineers; Major C. W. Raymond and Capt., now Major W. H. Bixby, all of the Corps of Engineers, U. S. A.

A SLIDE-RULE SEWER COMPUTER, which is an application of the Kutter formula to a slide-rule for use in obtaining the discharge, diameter or grade of sewers, has been devised by Mr. B. H. Colby, M. Am. Soc. C. E., Sewer Commissioner and Member of the Board of Public Improvements of St. Louis, Mo. All problems relating to egg-shaped as well as circular sewers can be solved by this simple instrument; and the results are guaranteed to be correct according to Kutter's formula. The computer is made of box wood and is 21 ins. long; it is manufactured and sold by the A. S. Aloe Co., of St. Louis.

STREET RAILWAY TRACK AND TRACK JOINTS.*

By M. K. Bowen.**

In considering this subject I have found that the life of a rail was measured by the wearing out of the head, and that less than 12% was worn away before we sold the old rail for scrap; hence the deduction that the point of contact between the wheel and the rail, or the bearing and wearing part of the track, was a most important consideration. The treads of wheels of street railway cars are made conical in order to center the car on the track. If the wheel were not coned, the wheel which once got behind, or an axle which once assumed a position not at right angles with the truck, would be apt to remain in its faulty position during the entire trip, requiring excess of power to haul the car, and abnormal wear of wheel and rail, resulting in sharp-flanged wheels and short life of rail. If the beveled tread is run on a flat-top rail, as in Fig. 1, all the bearing will be at A.

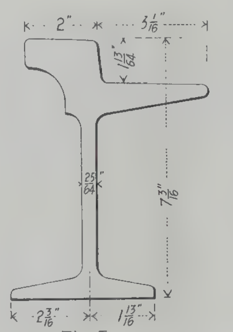

Fig. 5.

Fig. 5.—7-In. Girder Rail for Use with Chairs; Chicago City Ry. Co.

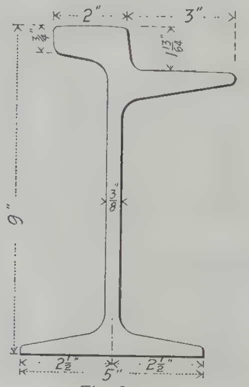

Fig. 6.

Fig. 6.—9-In. Girder Rail for Use Without Chairs; Chicago City Ry.

Fig. 2 is a section of a new and old car wheel which shows clearly the manner in which the tread of the wheel will wear if used on a rail with no bevel. The record of car miles of this wheel is not known, but no doubt a great amount of energy was lost before it had worn down to its most economical state. Fig. 3 shows a rail taken from the State St. cable track after 8 years' wear, during which time 8,000,000 car wheels passed over it. Fig. 4 shows a rail taken out after 11 years' wear. The rail should have been taken out three years before, but owing to impossibility of getting rails at the time and the Columbian Exposition coming at that time the track was not rebuilt. The true rate of wear cannot be found, as the flange of the wheel had begun to run on the flange of the rail long before it was taken out. The dotted lines show an interesting state of affairs. This section shows the wear due almost entirely to wagon traffic. Fig. 5 shows the rail used at the present time in our track construction with chairs or tie-plates. The rail weighs 83 lbs. per yd. and has a head 1 3-16 ins. high, beveled as described to conform to the car wheel tread for two-thirds of its section from gage line across the head. Fig. 6 shows the rail used in our electric construction without chairs or tie-plates. The rail weighs 90 lbs. per yd., and also has a head 1 3-16 ins. high, beveled as described. The experience of the Chicago City Ry. Co., which first tried this form of head, has been that it saved wear of both rails and wheels, increasing their life by about 35%.

The weakest part of the track construction is in the rail joints. Once weakened they rapidly grow worse, and not only are the rails worn at such joints, but the rate of wear of the car equipment is greatly increased. We want some method of keeping the rails from pulling apart at the joints (due to contraction and spreading outward) and from bending down at the joints (due to the pounding and weight of the cars). The joint I have used for the past year is a cast-welded joint. This has been found to give perfect satisfaction as a joint; it is strong and substantial, as has been proved by its holding under the extreme changes in temperature for which Chicago is noted. In 1895 there were 17,000 joints put in on the Chicago City Ry. Co.'s lines, and of these only 154 joints were lost. The joint in comparative tests has been shown to be far stronger than the rail itself, and such breakages as have occurred were due to flaws in the metal. The metal cast around the joint has eight times the cross-sectional area that the rail has. Hence, considering steel as four times as strong as cast-iron, the joint is twice as strong as the rail. It has been found in some cases where this joint was used at crossings with other tracks, the tracks were apt to be pulled out of shape through the changes of temperature. To overcome this the joint nearest the crossing should be anchored in a substantial manner.

The method of making the joint is as follows: The rails at the joint are scraped and brightened, a cast-iron mold is placed around the joint, making a tight fit, and into this is poured the molten iron, 25% scrap, 25% soft and 50% hard silicon pig. The metal in contact with the mold begins to cool and forms a crust while the interior remains molten. This crust continues to cool and at the same time contracts, forcing the molten metal strongly towards the center, which makes a solid and rigid joint. The top, or bearing part of the head of the rail is afterwards filed off perfectly level so that it is very difficult to detect a joint by riding over it or looking for it. Upon breaking a joint which has been well cast, three spots (1½ to 2 ins. diameter) will usually be found where amalgamation has taken place between the rail and cast portion; one on each side of the web and the other on the bottom. I cannot recommend this joint with certainty as a bond for carrying electric current, as there are occasional joints where no such amalgamation has taken place, thus destroying the effect as a bond of all joints in that line of track. To overcome this difficulty I have adopted the plan of bonding all joints. However, future experiments and care in the casting of joints may develop greater efficiency as a bond.

The following is an outline of the specifiations for track construction used by the Chicago City Ry. Co., and Fig. 7 shows a section of this track:

Excavation.—Excavate to a depth of 9 ins. below the established grade of the street, taking out all dirt for a width of 18 ft.; then excavate for each tie to a depth of 5 ins. leaving the earth between the ties in place.

Ties.—The ties should be of good sawed white oak 5 × 8 ins., 7 ft. long, free from sap; they are laid 30 ins. c. to c., directly upon the ground, and thoroughly tamped with medium-size broken stone.

Rails.—The rails to be used are 9-in. girder rails, 5 ins. base, 60 ft. long; the head to be beveled for two-thirds its width to conform to the bevel of the car wheel. These are laid on the ties and fastened with ½ × ½-in. spikes, 4½ ins. long, 8 spikes to a tie. Double nut tie rods, 1¼ × ⅛ ins. are used, 6 ft. apart; the first and last to be 3 ft. from the ends of the rail. The rails are to have vitrified brick or wooden filling between the paving blocks and the web on each side.

Paving.—The road bed is now filled to within 8 ins. of the top of the rails with medium fine limestone, thoroughly tamped. Upon this are placed 1½-in. hemlock boards running lengthwise of the track. Upon this layer of boards a 1-in. layer of clean sharp sand is laid; and upon this are laid the paving blocks, which should be No. 1 white cedar. 6 ins. high. After being laid the joints are to be filled with good gravel or a limestone screening, tamped in place, the top of paving blocks to be even with top of rail both inside and outside.

Gage.—The gage must be 4 ft. 8½ ins., or ¼-in. wider than the gage kept in the shop for gaging car wheels.

Level.—There must be not over ⅛-in. difference in the height of two opposite rails. Any amount above this will be considered sufficient cause for rejecting such part of track and rebuilding or re-surfacing the same. The foundation should be solid as it is possible to make it. The ties should be of such material that their life will be about equal to that of the rail, if anything a trifle more. The expense of taking up and replacing pavement and repairing defective ties is very great. The wood most generally used, and the one which gives the best satisfaction is good sound white oak free from sap. Its life is about 8 to 10 years under ordinary circumstances. The nature of the soil has considerable to do with the life of the tie.

Brace chairs in place of tie rods cannot be recommended for use with high rails, as they are very apt to bend over in time, but with shorter rails this will not happen.

The paving of a street upon the right-of-way is generally regulated by municipal authorities. Wooden blocks are extensively used in the smaller cities, but in the larger ones they soon wear unevenly and require replacing. Granite block paving is by far the most durable, lasting under ordinary wear in cities 30 years, and should be used where the street traffic is at all heavy. The blocks should be hard, but not liable to become slip-nery by use, the average size being 4 × 8 × 12 ins. I advocate small blocks, even as low as 3 × 6 × 10 ins.

---

*Abstract of a paper presented at the convention of the American Street Railway Association at St. Louis, Mo.

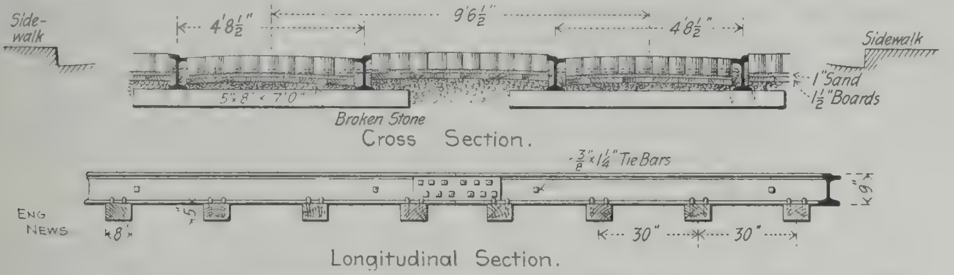
**Superintendent, Chicago City Ry. Co., Chicago, Ill.

The cost of one mile of double track with paving for 18 ft. in width of right-of-way, as above specified, based on Chicago prices, would be as follows:

283 gross tons 9-in. 90-lb. rails, at $33	$9,339
4,224 white oak ties, 5 ins. × 8 ins. × 7 ft., at 38 cts.	1,605
352 cast-welded joints, at $3.50	1,232
1,760 tie-rods, at 15 cts.	264
33,792 spikes, ½ × ½ × 4½, at 1 ct.	338
42,240 ft. of wood filler, at ½ ct.	2,112
Labor, at $1 per 1 ft. of D. B.	5,280
10,560 sq. yds. cedar block, at 30 cts.	3,168
146 sq. yds. sand, at $1.25	183
445 cu. yds. crushed stone, at $1.50	668
10,560 sq. yds. gravel and dressing, at 8 cts.	845
10,560 sq. yds. hemlock boards, 2-in., 8 cts. sq. yd.	845
	$25,879

If granite had been used instead of wood block the cost would have been $12,708 more.

The question as to the right time to reconstruct a track is one of the greatest importance as it often involves the expenditure of thousands of dollars. The task of solving this question was brought before me not long ago concerning the State St. cable track, which had reached a deplorable condition. From an examination I guessed that it was time to rebuild the track. This involved a very large expenditure, and to make sure of my guess I had run over the line a car weighing 8,665 lbs., attached behind a grip car by means of a recording spring balance or dynamometer. This test car was then run over a track newly made at the same speed as over the old line; the dynamometer showed that it took 13.75 lbs. more pull per ton to haul cars over the old line than over the new. The average speed of cars on this street is 12 miles per hour. The excess power required to haul one ton was 0.44 HP., and the excess cost of hauling one ton one hour was $0.0088. The number of tons hauled one mile per year on this track was 45,147,537, and the time required to haul one ton one mile was five minutes; and 45,147,537 tons hauled at a given speed for five minutes is equal in work done to 3,762,295 tons hauled at the same speed for one hour; 3,762,295 multiplied by $0.0088 equals $33,108, which is the excess cost per year for hauling cars on account of bad track. It is estimated that the new track with cast joints will last 12 years, and as there will be no low joints the draw bar pull will not increase much until the rail is worn down sufficiently to allow the wheel to run on the flange, so the annual saving will be nearly $33,108, during the life of the rail, and the total saving will be $397,276, which in 12 years will pay principal and interest on $293,444, which is the amount we could profitably expend in repairs. The actual cost of rebuilding this track was $61,670.



Cross Section.

Longitudinal Section.

FIG. 7.—STANDARD TRACK CONSTRUCTION; CHICAGO CITY RY.

This caused me to plan a scheme by means of which dynamometer or power ratings could be taken and automatically traced on paper, showing the condition of the track at all points, faults of gage, level or joints; and excess power in consequence of defects, side by side. Further, instead of representing defects in inches and the excess of power in foot-pounds to make the instrument show them in dollars and cents per ton of load when capitalized, which would show, multiplied by the ton miles on any road tested, the amount that could, with good management, be expended on track reconstruction, or rebuilding. The apparatus devised for this purpose is what we call an indicator car. I do not know of another in use by a street railway company, and have found only one other (very dissimilar) in existence on a steam road, after I had the plans of mine finished.*

This car shows graphically high and low rails, low joints and variations in gage, drawbar pull and track level. The car consists of a platform, 8 × 10 ft., mounted on a single truck, no springs being used. Midway between the two end axles is one which is fitted with wheels which record defects of joints or gage. After use and calibration of instrument it will be more valuable and the dynamometer will not be required, as any man using this car constantly will become so accustomed to the value of defects that a glance at the profile will tell him what money he may, with economy, spend for rebuilding a track or repairing it. The dynamometer consists of two draw bars, one at each end of the car, and extending beneath the platform to within a distance of about 1 ft. of each other. Between the two adjacent ends of the draw bars a spring is placed, and the amount of pull required to draw the car along the track in either direction is recorded by a recording arm, which is connected to the spring with a wire. The apparatus for showing the variation in the level of the tracks is mounted on the platform and consists of two cups of mercury (having a connection between them by means of a pipe) and into which dip two plungers connected to a recording arm. The paper on which the record is taken unwinds at a uniform speed of 1 ft. per 1,000 ft. of track. The car is fastened to an ordinary car, which is drawn over the tracks by horses (or any motor car) made to go at as even a speed as possible. The results shown by a recent test trip are very interesting to campare.

Fig. 8 is from an old track—the joints were the ordinary ones, and were spread far apart, and the rails are low at each joint; this is distinctly brought out by the record. The gage is also uneven. It would appear from the record that the rails spread at each joint. The dynamometer pull is very unsteady, showing the effect of low joints and uneven gage. Fig. 9 is a record from a new track; here we can observe hardly any joints or variation in gage, and the dynamometer pull is more steady. Occasionally high points are observed, but they are due to unsteadiness of speed. A person riding on this track will not be able to detect any joints. This track has the cast-welded joint. We find from the data obtained by use of this car that we could afford to expend $7,383 per mile to repair the old track. The estimated cost of repairing this track, leveling and casting new joints, is $1.740 per mile.

The track maintenance during the year 1895 for the 184 miles of track of the Chicago City Ry. Co. cost $158,217, and represented 17.75% of the total operating expenses. This excessive cost is largely due to a partial or complete rebuilding of many miles of track.

Discussion.

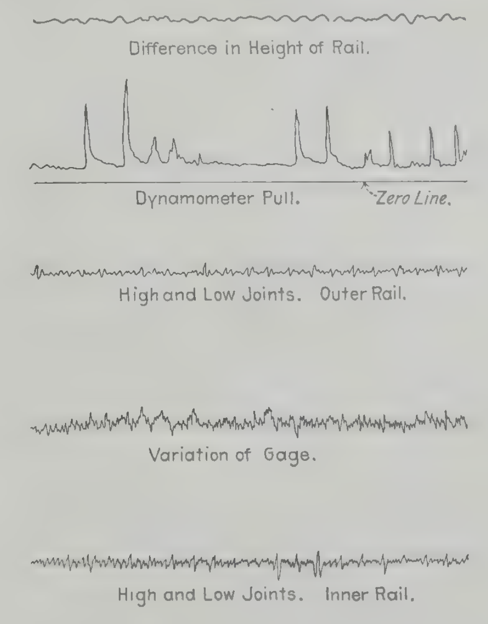
Mr. Robert McCulloch.—We have one piece of track which is 13 miles long, with cast-welded joints, most of it being of 60-ft. rails. We have not an ounce of copper nor a bond of any kind on the entire track. We have made tests of all sorts, with delicate instruments, graded to the thousandth part of a volt, tested as long and as short lengths as possible, sometimes a mile and sometimes a single joint, and have found in most instances that the carrying capacity of the joint was greater than that of the rail at any other place. We have found no necessity for bonding, our contact is perfect at the extreme ends of the rail; and I do not believe it is necessary to bond a welded track. The oldest joints we tested were about six or eight months old.

Mr. Bowen.—For a small road it would be better to let the contractors repair any broken cast-welded joints. For a large system it would probably be better to keep a cupola; you are always building more or less track and doing a considerable amount of repair work. A large system is generally building new track, and you could use a machine and make it pay for itself. The joints that failed, failed on account of contraction, due to very cold weather, in mid-winter. With the first cold snap, the contraction of the rails pulled 154 joints apart. The joints were then repaired, and since then they have gone through the summer the same as the other joints. They were cast in mid-summer, during the night hours. When the joints do part, it is for two or three inches, so that you can see them readily. If there is any oxidation between the joint and the rail, I hardly imagine it would do any harm unless it was sufficient to loosen the cast-iron from the rail proper. In that case it would come apart 3 ins. In repairing a break with a space of 3 ins., we saw a piece of rail and put it in, and recast around the entire two joints.

Mr. Goff.—I have in mind a track which was made up with cast joints in the winter, and in the summer time it seems to be out of line all the time. The car has a waving motion over the track. Do you have any trouble of this nature?

Mr. Bowen.—That comes from the casting. You will find as you put your mold on to cast the joint that the rails have contact at the ball and not at the flange at all. If you are not careful the rail will go out and go up, on account of the majority of the iron being underneath the rail. The contraction in cooling will push it up and push it out. In order to prevent that we put a clamp on the rail when casting it and push it in ¼ in. and down ¼ in. We like to cast at a temperature of between 40° and 50°. There were one or two cases of rails pulling apart. Instead of the fracture being just at the joints, it was some little distance back, probably where the difference between the extreme heat and the ordinary temperature of the rail left a partial fracture.

Mr. Littell.—We have no welded joints in Buffalo. We have the ordinary track laid with 9-in. rail, 94 lbs. per yd. Summer before last we put down some 9-in. rail in hot weather, forcing the rails just as close as we could, leaving them uncovered over night. In the morning we drove the rails up as close as we could, and put them together with a 12-bolt splice bar, 1-in. bolts. We got along very nicely for a time, but winter before last we had one of the 30-ft. rails pull in two 13 ft. from the joint.



Difference in Height of Rail.

Dynamometer Pull.

High and Low Joints. Outer Rail.

Variation of Gage.

High and Low Joints. Inner Rail.

Fig. 9.—Track Indicator Diagrams, New Track.

Mr. Seely.—We have had 90-lb. girder rails pull in two, on grade of about 5%. We have this occur every winter; the rails break right in the center. The joints are driven too close together. We also find that with the high carbon rails we are using it is almost impossible to cut them with the ordinary tools; we require special devices for sawing rails in two. In sawing rails, if you have to turn them over, they will crack all the way down the center, and we are compelled to handle them with the greatest care.

Mr. McCormack.—Our company in Brooklyn put in 2,000 cast-welded joints on the 94-lb. 9-in. girder rail, and out of that number there was only one which pulled the rail apart; the rail broke about 4 ins. from the end.

Mr. Bowen.—We have 32,000 cast-welded joints, and pay the Falk Co. a royalty for each joint.

---

*The most complete track indicator, or dynagraph car, is that of Mr. P. H. Dudley, but the Pennsylvania R. R. and some other lines have indicator cars for a similar purpose.—Ed.

Changes to standing advertisements must be in hand on Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

We give a considerable part of our space this week to the papers and discussions at the annual convention of the American Street Railway Association, held at St. Louis last week. The Association is to be congratulated on the excellence of the papers which were read at St. Louis, which seem to us to be distinctly superior as a whole to those which have been read at any preceding convention of this Association. The progress and changes in electric railway engineering have been so rapid in every department during the few years since the electric railway came into general use that it requires vigilance to keep pace with them. Existing literature on electric railway engineering that is of real value to the engineer engaged in actual practice is far from abundant. We believe, therefore, that the papers in this issue on overhead work, power-plant design, and especially the notable features of track construction, will be appreciated by our readers.

◆

In the October advance sheets of "Consular Reports," Commercial Agent H. C. Carpenter, of Furth, Germany, gives some very sensible advice to American manufacturers seeking a broader market for their goods. He tells them that there is such a market in Germany; but it can not be secured by sending catalogues, circulars and other advertising matter to U. S. Consuls abroad under the expectation that these officials will act as their agents. Mr. Carpenter says that the leading industry about Furth is the manufacture of looking-glass plate, and over $1,000,000 worth of this product is annually exported to the United States. But the German manufacturer goes after his market, exhibits his goods, in person or through trusty agents, and by this personal and persistent effort he sells his manufactures. It is pointed out that this rule would work both ways, and Mr. Carpenter shows that there is a fruitful field in Germany for the American manufacturer who will more closely follow German methods in the development of foreign trade. In the line of furniture particularly, there is abundant room for the sale of the well-made solid wood furniture that the United States produces so cheaply. Mr. Carpenter paid $150 for a German dining set, of pine, thinly veneered with a poor quality of oak, which split so badly in six weeks that it had to be repaired. A finer and more durable set could have been purchased in this country for $60. He says that every piece of furniture made in Germany, even down to the plainest, costs from two to three times the price of a better article made in the United States. Farming implements and machinery, house building machinery, boots and shoes are all referred to as products for which Americans could surely find a market in Germany. But the goods themselves must be shown to the Germans, agencies must be established and the American dealer must "hustle for business," to use the expressive remark of Mr. Carpenter. The German leaves the home market to regulate itself while he personally seeks the markets of the world; and we must do the same to extend trade beyond our own boundaries.

◆

The well-known firm of Yarrow & Co., of London, builders of steam yachts and torpedo boats, are said to be considering the establishment of a new works on the Continent with a view, if the result be as satisfactory as is anticipated, of closing their English yard. "Engineering," of Sept. 25, devotes its leading editorial to the subject. The principal reason given is that "foreign countries evidently offer to an astute and successful English manufacturer better opportunities of conducting his business than does his own land." Mr. Yarrow, it is stated, formed one of the party of the Institution of Naval Architects who last spring paid a visit to Germany and inspected many of the shipyards there. "Not a few of the members," says "Engineering," "came back with the unhappy conviction that they would like to exchange yards with at least one they saw during their travels, and that if British builders were to maintain their supremacy they must scrap a good deal of their plant and spend thousands of pounds on new machinery." The chief advantages in favor of a location in Germany as compared with England, are, apparently, the greater cheapness of labor and the greater freedom from obstruction by the action of labor unions.

◆

SPECIFICATIONS FOR WATER-TUBE BOILERS.

The city of St. Louis recently advertised for bids for eight water tube boilers for its No. 3 pumping station, at Baden, and the result of the bidding shows some remarkable features which we deem worthy of comment. From the printed specifications issued by the Water Commissioner, upon which bids were asked, we extract the following:

> 1. The work to be done consists in furnishing designs and plans, materials, tools and labor and building, transporting and erecting complete in place in the boiler house at High Service Pumping Station No. 3, Baden, eight boilers with furnaces, settings, valves, gages, breeching and smoke flue to core of stack.
>
> 2. The contractor shall submit, with his bid, evidence in writing, satisfactory to the Board of Public Improvements, of having obtained with boilers similar to those proposed to be furnished under this contract, an efficiency with common Illinois coal of not less than 65%.
>
> Design.
>
> 3. The boilers shall be of the water tube type, having straight tubes, removable from the front and accessible and open at both ends, and no tube shall make a greater angle than 45° with the horizontal, except front and rear connecting pipes between drums and headers. No stays or obstructions of any kind shall be placed inside the water tubes.
>
> The boilers shall be designed and built with special reference to the easy removal of the tubes and access for repairing and cleaning all external and internal surfaces. No part of the boilers or fittings shall extend more than 21 ft. above the boiler room floor.
>
> The furnaces shall be designed to develop the specified capacity of the boilers, without producing smoke, when burning common Southern Illinois coal, and shall have ample combustion chambers.
>
> Furnaces using steam jets in the fire box or combustion chamber, will not be permitted. Mechanical stokers, or furnaces operated by means of a secondary engine, will be tested to ascertain the amount of steam thus used, and this amount of steam will be charged against the boilers in determining the capacity and efficiency.
>
> 4. The boilers to be designed for the natural draft of the smoke-stack now under contract, and shown on plans on file in the office of the Water Commissioner.
>
> 5. The boilers shall be designed for a working steam pressure of 150 lbs. per sq. in., with a factor of safety of five on minimum sections.
>
> 6. Each boiler shall have an evaporative capacity of 9,000 lbs. of water per hour from a temperature of 100° F. into dry steam at 70 lbs. gage pressure, or the equivalent of this capacity.
>
> 7. The boilers shall be set in four independent batteries having passage-ways of about 6 ft. in width between them. Each boiler to be provided with walls, settings, valves, gages, smoke-breeching and dampers necessary for operating or repairing it independent of the other boilers in the house.

The clauses of the specification following those above quoted relate to fire-fronts, dampers, valves, steel for drums, settings, tools, quality of material, workmanship, foundations, etc. These clauses number 44 in all, and are given in considerable detail, but they contain no requirement especially difficult to fulfill. After these are the following:

> Test for Capacity, Efficiency and Smoke Record.
>
> The boilers shall be tested for capacity and efficiency by the Water Commissioner. One or more boilers shall be tested at a time as may be directed. All boilers under fire in the house shall be tested.
>
> The contractor shall furnish firemen at his own expense during all tests, and shall be given opportunity to make preliminary trials before submitting the boilers for formal tests.
>
> The coal burned during the official tests shall be Mt. Olive Illinois coal, having a calorific value of 11,000 B. T. U. per lb., furnished by the city of St. Louis, and delivered to the contractor in the coal house. Contractor will be allowed to pick, air-dry or fork coal if he so desires.
>
> Coal will be sampled and weighed as it comes into the boiler room. Calorific value of coal shall be determined with a Thompson calorimeter, with no correction for moisture.
>
> No allowance shall be made for unconsumed carbon in ashes, nor for temperature of air entering furnace.
>
> During the preliminary testing of the boilers by the contractor, observations on smoke will be made, and until the record thus obtained is satisfactory to the Water Commissioner, the contract tests for capacity and efficiency shall not be made.
>
> Repairs.
>
> One year after the test for efficiency, and before the final estimate has been given, the Water Commissioner will make an examination of the boilers and furnaces and any part or detail found to be defective or injured through bad material or faulty design, shall be replaced by the contractor at his own cost and expense, to the complete satisfaction of the Water Commissioner.

Then follow stipulations in regard to time of completing the work, agreement that the contractor will not sublet the work, and that he will protect the city from demands for patent royalties, damage suits, etc. The guarantees of capacity and efficiency and the premium and penalty clauses are as follows:

> The party of the first part shall further agree that each boiler furnished under this contract shall have an evaporative capacity of 9,000 lbs. of water from a temperature of 100° F., to steam at 70 lbs. gage pressure in one hour, or the equivalent of this capacity. Steam generated under the above conditions shall not contain more than ½ of 1% of moisture. The capacity to be determined by the Water Commissioner.
>
> The party of the first part hereby agrees that the boilers furnished under this contract shall attain, during a test of 24 hours or more, an efficiency of 70%; i. e., they shall utilize in heating and evaporating water, 70% of the total heat units contained in the coal as determined with the Thompson calorimeter.
>
> The party of the first part further agrees that in case either of the eight boilers fails to attain an efficiency of 70% during the efficiency test he will pay to the party of the second part, as an agreed measure of damages for lack of efficiency, an amount to be determined in the ratio of $500 for each per cent. which the efficiency of each boiler falls below 70%.
>
> In case any boiler, during the efficiency test, exceeds an efficiency of 70%, the party of the second part agrees to pay the party of the first part, as compensation for the superior efficiency of the boilers, an amount to be determined in the ratio of $250 for each per cent. which the efficiency of each boiler exceeds 70%.

The eight-hour labor ordinance of the city of St. Louis, approved Dec. 22, 1891, is then made part of the contract, as follows:

> All contracts hereafter entered into where the city of St. Louis is a party, for the doing of any kind of work or labor for the city of St. Louis, including work on all public buildings, works and enterprises, shall contain the following terms and conditions: (a) That the men, persons or laborers who may be employed in the doing, prosecuting or accomplishment of such work done by the contractor with the city of St. Louis, or any one under him, or any person controlling the said men, persons or laborers, shall not be required to work more than eight hours per day; (b) That in case of the violation of such provisions of such contracts, the Mayor shall immediately declare such contracts cancelled and forfeited, and the work being done under such contracts shall be relet in the manner provided for the letting of such work, and such contractor shall thereafter be ineligible to bid upon such work under such reletting, and the difference in the cost of doing such work under such contract so cancelled and forfeited, and under such reletting, shall be sued for on the bond of such contractor so violating such contract.

It will be observed that there is not a word in the specifications concerning the size of the boilers or furnaces, the areas of grate and heating surface, nor the dimensions of any of the parts. Instead of specifying how large a boiler and how large a furnace is desired, the specification merely states that each boiler shall have an evaporative capacity of 9,000 lbs. of water per hour from feed water at 100°F. into steam at 70 lbs. pressure, that the furnaces shall be designed to develop the specified capacity of the boilers without producing smoke, and shall have "ample" combustion chambers, and that during a test they shall utilize 70% of the heat units contained in the coal, as determined by a Thompson calorimeter, The result of the advertising for bids was that only four bids were received, as follows:

Water Department, Letting No. 5034, Sept. 8, 1896.
Abstract of Proposals for Eight Water Tube Boilers at Baden:

Heine Safety Boiler Co., St. Louis, Mo.	$24,950
John O'Brien Boiler Works Co., St. Louis, Mo.	22,300
Geary Water Tube Boiler Co., Oil City, Pa.	50,000
Abendroth & Root Mfg. Co., New York city	52,000

With the bids there was received a protest from the Heine Safety Boiler Co., dated Sept. 8, stating that it had reasons for believing that the boiler tendered by the John O'Brien Boiler Works Co. were "to all intents and purposes Heine Safety Boilers, and as such directly infringe our patents."

In response to this the O'Brien company filed, on Sept. 10, an opinion by Knight Bros., patent attorneys, dated Nov. 25, 1895, to the effect that a boiler made according to a certain blue print furnished by the O'Brien company could be built without infringing any one of three Heine patents, because all the patents had expired. The Heine company then, on Sept. 12, wrote a letter to the Water Commissioners, in which they say:

> We have two suits against the city of St. Louis connected with its use of the Geary boiler. The more important one and the one which will chiefly warrant the consideration of your Board is that one which is brought upon our patent No. 529,741, issued on Nov. 27, 1894, to E. D. Meier, and by him duly assigned to this company.

Mr. M. L. Holman, M. Am. Soc. C. E., Water Commissioner of the city, to whom we are indebted for copies of the specifications and of the correspondence relating to the Heine company's protest, now writes us:

> As the city desires to purchase boilers and not law suits all bids were rejected. The department is now at work on plans and specifications for boilers preparatory to a new letting.

Mr. Holman also furnishes us the accompanying table, which he says contains all the data which could be obtained from the drawings and descriptions submitted with the bids:

bid; but, according to the dimensions of the thing offered, the O'Brien company's bid would have been by far the lowest, because for a little more money it offered boilers 48% larger. No such question arose, however, for the O'Brien company not only offered boilers 48% larger, but its price for them was $2,650 less, or 10½% lower than the Heine bid.

The element of guesswork appears to have been an important one in the calculations of one, if not of both, of these bidders, for, having the same performance to guarantee, one bidder offers 6.94 sq. ft. of heating surface per HP., and the other 10.27. Dividing the 9,000 lbs. of water to be evaporated per hour by the area of heating surface offered, one bidder expects to evaporate 4.93 lbs. of water per sq. ft. of heating surface and the other only 3.14 lbs., although the second provides 25% more grate surface, which should be capable of burning, with equal economy, 25% more fuel. The horse-power of each boiler (30 lbs. of water from 100° F. to 70 lbs. pressure being taken as a horse power), is 300 in both cases, or 2,400 HP. for the eight boilers. One bidder offers his boilers at $10.40 and the other at $9.29 per HP., both very low figures for water-tube boilers, including settings. Figuring the price per square ft. of heating surface, one bidder offers 16,677 sq. ft. for $24,950, or $1.50 per sq. ft., while the other offers 24,668 sq. ft. for $22,300, or $0.90 per sq. ft. The other two bidders, whose bids do not give the dimensions of their boilers bid, respectively, $21.67 and $20.83 per HP., or more than double the figures named by either of the two lower bidders.

Perhaps the premium and penalty clauses of the specifications, in connection with the element of guesswork, had something to do with the fixing of prices by the several bidders. The penalty is $500 for each per cent. which the efficiency of each boiler falls below 70%, and the premium is $250 for each per cent. which the efficiency of each boiler exceeds 70%. For the eight boilers one per cent. falling off from an efficiency of 70% would mean a penalty of $4,000, and one per cent. excess of 70% would mean a premium of $2,000. One bidder might reason as follows: "The fair price for my boilers is $30,000, but as water tube boilers with Illinois coal, the coal being tested with the Thompson calorimeter, have in some tests shown 75% efficiency, I can obtain $10,000 premium, and therefore I can afford to bid as low as $20,000, but will put on a few thousand more to cover the risk." Another bidder might reason thus: "While water-tube boilers have shown 75% efficiency, both Illinois coal and Thompson calorimeters are apt to be very erratic, and there is always a likelihood of slight differences of condition making a variation of several per cent. in a boiler test. I had better not be too confident that I can obtain 70% efficiency, but will assume only 65% as a fair margin. The fair price of my boiler is $30,000, but 5% falling off in efficiency would subject me to a forfeiture of $20,000, so, to be safe, I must bid $50,000."

Data on Boilers for High-Service Pumping Station No. 3, Baden, Compiled from Drawings Submitted with the Several Bids.

Eight water tube boilers, complete)		$24,950	$52,000	$50,000	$22,300

[1] These figures are scaled from the drawings—all others are taken from dimension figures.
[2] Steam space given for the O'Brien boiler includes a steam-drum 30 ins. diameter × 7 ft. long.

From the above table it will be seen that two of the four bidders did not furnish with their bids the dimensions of the boilers and furnaces, upon which they bid, and from the specifications of the Water Commissioner it does not appear that there was any necessity for the other two bidders to give the dimensions of their boilers. From the figures given by these two bidders, however, we are enabled to form an idea of what they proposed to furnish. According to these figures both of these bidders intended to furnish a double grate, consisting of upper and lower portions, probably the Hawley down-draft furnace. The O'Brien company offered 24.6% more upper grate, 25.4% more lower grate, 48.7% greater number of water tubes, and 47.9% greater extent of heating surface than the Heine Co. The O'Brien and the Heine boilers being practically of the same type, as stated in the Heine protest, and the rating of boilers of the same type being proportional to their heating surface, it appears that the O'Brien company offered about 48% more boiler than the Heine company. If the O'Brien company's price had been a little more than the Heine company's it would have been an interesting problem to determine which was the lowest bid.

According to the letter of the specifications, had the Heine boilers been offered at the lowest price, the Heine company's would have been the lowest

Another remarkable thing about these bids is that only four bidders of water-tube boilers are represented. The specifications exclude those forms of water-tube boilers in which the tubes are not straight, or in which the tubes are at a greater angle than 45° with the horizontal, but they appear to be sufficiently wide to allow bids from the builders of the Babcock & Wilcox; Cahall (horizontal); Edgemoor; Gill; Campbell & Zell; National and Standard boilers, and since a water-tube boiler may be built under the specifications without infringing any unexpired patents, it would appear that they might be met by any boiler maker who has the proper facilities for manufacturing a water-tube boiler.

There is no mysterious property in any one of the several makes of water-tube boiler of the common form, in which the tubes are straight and inclined at an angle of less than 45° to the horizontal, when of approximately the same dimensions of heating and grate surface, supplied with the same kind of furnace, say, the Hawley down-draft, and using the same coal, which should cause one to give any higher efficiency than another. Differences in the apparent efficiences are undoubtedly obtained when the dimensions are different, and when there are differences in the furnaces, in the coal, in the calorimeter by which the coal is tested, in the fireman, and in accidental conditions of the test, such as thickness of bed of coal carried and force of the draft. But none of these difference are due to the type of boiler, and none of them would seem to justify the inclusion in specifications of premiums and penalties based upon "efficiencies" which are calculated from tests of a few grains of coal in an imperfect calorimeter, and the exclusion of what should be the most important feature in a moiler specification, the dimensions of the heating and grate surface.

In saying this, we by no means wish to be understood as condemning the premium and penalty feature in specifications in general. On the contrary, we have in the past advocated this feature in specifications as eminently calculated to stimulate good work on the part of the contractors, and at the same time avoid any difficulty or litigation in case the completed work does not fulfil the contract guarantee. But where a performance is specified in a contract and premiums and penalties are fixed for exceeding or falling below it, that performance should actually indicate the value that the contractor is giving and the purchaser is receiving. The performance of a boiler based on the per cent. of calorific value in the coal burned in its furnaces which is used in making steam, is subject to such large percentages of error in its determination that it does not fulfil this requirement, as we showed in our issue of June 11, 1896. The result of the bidding at St. Louis seems to fully justify what we then said.

According to the letter of Mr. Holman, already mentioned, it appears that the Water Department has learned a lesson from the results of the bids on these boilers, and instead of re-advertising for boilers on the same specifications, it is preparing plans as well as specifications preparatory to a new letting. If the plans are to be of a general character, showing the more important dimensions, but leaving particular details of connections of parts, etc., open for each manufacturer to bid upon those for which he has patterns and tools, well enough, but if the plans show details for which new patterns will have to be made or which can be made only by one or two builders, on account of patent restrictions, then we fear the Department will go to the opposite extreme from that of the first specifications, and by limiting the number of possible bidders prevent the city from obtaining low bids. In any event the results of the second letting will no doubt show a great contrast with those of the first, and one which should make an interesting chapter in the history of engineering specifications.

◆

LETTERS TO THE EDITOR.

A New Mississippi River Dredge.—Correction.

Sir: We note in your usually accurate journal that the capacity of the dredge we are building for the Mississippi River Commission is only "800 cu. yds. per month." As that is the minimum capacity per hour, the discrepancy is startling. In general we may state that it is a machine of just about one-half the intended capacity of the enormous dredge "Beta," whose design and performance were noticed at length in your columns some months ago, and the capacity of 800 cu. yds. per hour will probably be largely exceeded. One special feature of the design is that it is so far different from all usual arrangements of suction dredges with mechanical excavators as to be entirely outside of the principles claimed by A. B. Bowers as his invention. Yours truly,

New York Dredging Co.,
By H. S. Wood, Engineer.
World Building, New York City, Oct. 23, 1896.

◆

The Cement for the Melan Bridge at Topeka, Kans.

Sir: In view of the discussion created by the specifications for the Portland cement for the large Melan arch bridge over the Kaw River, at Topeka, Kansas, the information in the fourth of the "Industrial Notes," on p. 131 of the issue of Engineering News of Oct. 15, 1896, may be misleading. Aalborg Portland cement has been chosen under the specifications alluded to, for all parts of the work in which Portland cement will be used, and much of the 5,600 barrels required is now on the ground.

Yours very truly,
Geo. M. Newcomer,
Agent Aalborg Portland Cement Works.
66 Maiden Lane, New York city, Oct. 26, 1896.

(In the "Industrial Note" referred to it was stated that the Diamond brand of cement will be used. This is a natural cement, and according to the specifications published in our issue of April 2, 1896, this cement may be used in the foundation up to a level 1 ft. below low water mark. For all other parts of the work Portland cement will be used, and the very rigid specifications for it were discussed in our issue of May 7.—Ed.)

◆

Noisy Brick Pavements.

Sir: In your issue of Oct. 15 I noticed an article asking for possible explanations of the cause of the noise produced by the passage of vehicles over the brick pavement on McDonough St., Brooklyn. I think that you will find upon inquiry that the joints between the bricks in this pavement are filled with cement instead of sand or pitch. I have, as Borough Engineer, at Plymouth, Susquehanna Co., Pa., had a similar experience with a piece of brick pavement, in which the joints between the bricks for half the length of the street were filled with pitch. The joints between the bricks for the remainder of the street were filled with neat Portland cement. I have often noticed that a vehicle passing along the street would make considerable more noise in passing over that portion of the street that was cemented than it did in passing over that portion with pitch joints. I also know of a piece of pavement in a neighboring city where the joints between the bricks were cemented with like results.

Respectfully yours, Edward H. Post.
Wilkes-Barre, Pa., Oct. 21, 1896.

(Since making the query referred to we note a similar explanation from Mr. E. Adam, Engineer of the Board of Street Commissioners, of Newark, N. J. In this case the rumbling noise occurred in brick pavements with grout filling, and not on pavements with sand filling between the bricks, Mr. Adam was disposed to ascribe the cause of the noise to the slight lifting of the whole pavement from its foundation, by expansion. At the same meeting of the American Society of Municipal Improvements, Mr. N. P. Lewis refers to the experience in Brooklyn, and attributes the cause to the thawing out of the sand cushion, the bricks having been laid in cold weather. This thawing action left voids under the pavement, which would naturally increase the reverberatory effect. As the general experience points to the fact that the noise is much less when the joints are filled with sand or pitch, another explanation might be offered. The use of cement grout practically makes the covering of the street surface a monolithic sheet, fairly well adapted for the transmission of vibrations from traffic and the accumulative effect of sound waves. The use of sand or pitch in the joints acts as a deadener to the sound waves originating in any one brick, and consequently some considerable portion of the sound is absorbed or lost, and the resultant noise is decreased.—Ed.)

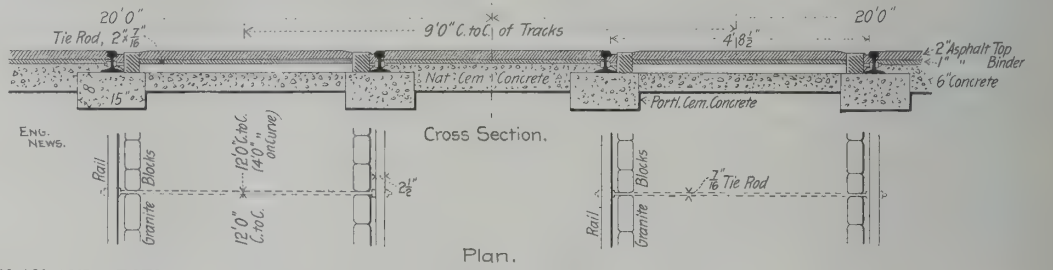
A PERMANENT STREET RAILWAY TRACK.

In discussing editorially "The Street Railway Track of the Future," in our issue of Oct. 15, we called attention to the anomaly which at present prevails in street railway construction of placing a mass of perishable timber beneath the pavement and at the same time using lavishly concrete filling, between, around or under the ties, according to the fancy of the engineer.

Since the publication of that article we have been favored by Mr. Geo. L. Wilson, M. Am. Soc. C. E., with drawings of a method of permanent track construction which has been adopted the past season by the Twin City Rapid Transit Co., operating all the street-car lines of St. Paul and Minneapolis. We print Mr. Wilson's letter with the accompanying plans as follows:

> Sir: The subject of street railway track is one of vital interest to all engineers connected with the maintenance of city streets as well as to the street railway companies themselves. As a method of permanent track construction has been adopted, the past season, by the Twin City Rapid Transit Co., that promises to solve the problem as outlined in your editorial of Oct. 15, I send you the accompanying plans, thinking they will prove of interest to engineers engaged in municipal work.
>
> The accompanying drawing is a partial cross-section of an asphalt paved street, with the track construction shown in detail. The rails are laid and brought to grade and line while supported on temporary wooden ties. As the work progresses, after the spaces between the cross ties and under the rails are concreted, the ties are removed and all holes are filled with concrete. The granite blocks along the track are set in place and then left from 10 to 14 days for the cement to thoroughly set, after which the asphalt surface is laid in the usual manner and traffic is resumed. It is an important matter in this construction that sufficient time be given for the concrete to harden before the track is put in service.
>
> The rail used with this construction is a T-rail, weighing 80 lbs. per yd., with a height of 5 ins. and a 5-in. base. The top corner of the head has a radius of 5-16-in. This rail gives good results for a T-rail, except that the depth is not sufficient to allow a proper depth of granite blocks. With a depth of 7 ins. much better results would be obtained in the writer's opinion. The rails are laid in 60 ft. lengths on tangents and 30 ft. on curves. All joints are cast welded.
>
> About six miles of track have been laid the present season, with this construction, by the company referred to, and it is believed that the work will prove a success. For the concrete beam under the rails, Portland cement is used and natural cement for the balance of the work.



PLAN AND SECTION OF PERMANENT STREET RAILWAY TRACK CONSTRUCTION, ADOPTED BY THE TWIN CITY RAPID TRANSIT CO.

We trust that all our readers in any way interested in street railway track construction will give this design the study it deserves. We have seen no more intelligent attempt anywhere to solve the problem of street railway track construction, and the results of experience with it will be awaited with much interest.

A comparison of this track with the very expensive track of the Chicago City Ry. Co., illustrated and described by its Superintendent on another page of this issue, gives rise to many interesting questions. We are without figures as to the cost of the Twin City construction, but we should judge it to be considerably cheaper than the Chicago construction. The former employs a considerably lighter rail, and one which can be bought for considerably less per ton than the girder rail with tram-head used on the Chicago City Ry. It dispenses entirely with ties, and with wooden construction of every sort. As for the relative durability of the two, there is nothing in the Twin City construction to wear but the rail, there is nothing perishable underneath to decay, and if the foundation is solid there appears to be no chance for the track to get out of surface, while the paving holds it absolutely in line. A comparison of the cross-sections will show that a T-rail laid in this way is actually less obstruction in the street than the girder rail with its broad head.

We cannot leave this subject without calling attention to the astonishing feature of the laying of hemlock boards underneath the pavement on the Chicago City Ry. tracks. This sort of paving construction by municipalities was given a black eye long ago; and it is surprising to see a street railway company building track at a cost of $25,000 per mile, and laying hemlock boards as a paving foundation between the rails.

◆

THE MODERN STREET RAILWAY POWER HOUSE.[*]

By Richard McCullough.[†]

The cost of power on a large road is only about 10% of the total operating expenses, hence while fuel economy is important, it is far more important that every machine shall be so designed as to insure absolutely reliable service and reduce the liability to break-downs to a minimum.

Location.

A large power house should be placed on a railway track so that coal may be cheaply delivered, and it is also desirable that the location should be where condensing engines may be used, unless the conditions will warrant the use of self-cooling condensers. If a location fulfilling these conditions may be found somewhere near the electrical center of distribution it is an ideal spot for a power house, but if in order to secure coal and water it must be moved from this point, it should, if possible, be moved in the direction of future extensions of the street railroads. The only excuse for not locating on a steam railway is where the interest on the cost of copper feeders running from the steam railroad tracks to the center of distribution would greatly exceed the cost of hauling of coal in wagons.

Building.

There is no reason why anything combustible should enter into the construction of a power house. The walls may be brick, the roof of slate, tile or iron, and the floors of concrete or iron. This obviates the necessity of carrying insurance, the saving of which will in a few years pay the extra first cost. In erecting the building it is advisable to decide first on the style, size and arrangement of the machinery so that no part of the building will interfere with the proper repairs, renewals and inspection of the apparatus. It is a common oversight for railway companies to let the contract for the erection of the power house building, and then find themselves hampered in the use of some particularly desirable form of apparatus by the shape or contracted area of their buildings.

Steam Generating Apparatus.

The proper fuel to use is that which will evaporate the greatest quantity of water per dollar's worth of fuel. It does not pay to burn too poor a quality of fuel, however, because slack containing a great quantity of ash and sulphur will cake and clinker on the grate bars, make a great deal of work for the firemen, and much ash to be removed. In cities where several competing grades of coal come to market, it would probably pay to have expert tests made to determine what grade of coal or what mixture is most economical for the work. In power houses handling large quantities of coal, where the coal is all delivered at the same place, as by rail or boat, the installation of coal and ash handling machinery will generally pay. The advantage of this form of apparatus is its saving in labor, and its disadvantages are its great first cost, its expensive maintenance and the fact that it is desirable for the best service that the coal should be fairly uniform in size, which is a requirement not always easily fulfilled.

In the East the use of mechanical stokers has grown to such an extent that no large power house is considered complete without them. In most of the Western cities, however, and especially in St. Louis, the mechanical stoker has not been a success.[*]

Boilers may be divided into two general classes, fire tube and water tube. In most of the more recent power houses, some form of water tube boiler has been adopted, as this type possesses some marked advantages over the fire tube. They are non-explosive, they may be operated at a higher pressure and consequently are more suitable for use with compound engines, they have a large heating surface and are quick to respond to calls for power, they occupy less floor space and are usually more intelligently designed than the other class. On the other hand, their first cost is greater, there is a greater number of joints to be looked after and the cleaning is more difficult, especially in those forms which use a curved tube. It has usually been considered that the efficiency of water tube boilers was much higher than the fire tube, but there is now a form of fire tube boiler being made consisting of a shell of large diameter and extra length, containing a large number of flues, which approaches the water tube boiler very closely in efficiency. The high efficiencies obtained in boiler tests are seldom reached in actual practice as they usually result not so much from excellence of design in the boiler itself as from careful and intelligent firing during the test.

---

[*] Abstract of a paper read before the St. Louis Convention of the American Street Railway Association.

[†] Electrician of the Cass Ave. & Fair Grounds Ry. Co., St. Louis, Mo.

[*] Recent information we have received from St. Louis contradicts this statement.—Ed. Eng. News.

The usual methods employed in heating the feed water are, first by the heat of the exhaust steam, and second by the heat of the escaping flue gases. There are numerous devices for utilizing the heat of exhaust steam, either by passing the exhaust through a number of pipes surrounded by the feed water, or by spraying the feed water across an opening through which the exhaust steam is admitted. Most of these devices are very simple in their construction. Care should be taken that the opening for the exhaust steam is never contracted, so that any possible back pressure on the engine is avoided.

The method of heating feed water by the heat of the escaping flue gases has been applied in apparatus under the general name of economizers. In the use of any device in which feed water is heated by the flue gases, care should be taken that the escaping gases will still retain sufficient heat for the maintenance of the necessary draft after part of their heat is taken from them by the feed water. In the case of power houses using natural draft, economizers should not be used where the draft is not already sufficiently strong, or is just barely strong enough for the work to be done. There are in operation, however, many plants using natural draft, discharging flue gases at a very high temperature, much higher than is necessary to maintain the required draft. Economizers used in such cases would result in a marked gain in economy.

Whatever system of heating feed water is used, the apparatus should be made abundantly large for the work to be done; first, that the water should pass through slowly and receive the full benefit of its contact with the heated gas or steam; second, that a large store of water may be kept on hand, which is of great service in case of a sudden demand on the boilers; and third, that the feed water heating apparatus may act as a water purifier.

With condensing plants the waste from the condensers is never at a greater temperature than 100° F., and if hot feed water is desired, the use of an economizer becomes almost a matter of necessity as the water from the pumps and the other non-condensing machinery would not have sufficient effect in heating the feed water of a large plant.

Several of the large power houses built during the last few years have abandoned the use of stacks for producing draft, and are operating by means of an induced draft produced by fans placed in the flue or short stack. In this case the stack is just high enough to clear the roof. This system has many advantages. First, there are no stacks to blow down or fall down, and this point is of special importance in a region subject to tornadoes. The second and most important advantage, however, is the absolute control which it affords in governing the fires, and this point will appeal especially to those power houses subject to sudden and rapidly changing loads. As an illustration of this may be cited the power house recently erected to operate the Baltimore Tunnel Road. A great part of the time there is no load on the power house as it is only operated when there is a freight train to be hauled through the tunnel. The manner in which the load is handled is as follows: The boiler room is supplied with blowers in place of stacks, and a slow fire is kept constantly under each boiler. When a telegram is received that a freight train is approaching, the blower is started, and on the arrival of the train, steam has been raised in sufficient quantity to supply the great demand put upon the boilers.

The Steam Piping.

In regard to the general plan of the piping, opinion is very much divided. Some favor a single-header with leaders to the engines. Others claim that a complete duplicate system is necessary, so that a failure in any part of the system need not cause a serious stoppage. The objection to a duplicate system is the greatly increased cost. In the installation of a duplicate system, it is only natural that the material and workmanship employed will be cheaper than if a single system were employed, because it is reasoned that if one side breaks down, there is always the other to be depended upon. The other side, however, is often never used until a case of necessity arises, and on account of this very lack of use, the valves and joints are apt to be found leaky and in bad condition when suddenly put in operation. A compromise system has been used in some cases in which all pipes are duplicated, each side, however, having only one-half the capacity required, necessitating the use of both sides at all times. In case of accident to one side the other half of the system may be used, at a disadvantage, of course, by increasing the steam pressure. The best plan, however, seems to be to use a single header divided at convenient intervals by valves, according to the size of the plant and the number of units employed, and to use only the best valves, material and workmanship. The power houses having the least amount of trouble with their piping are those having a simple system. All steam and hot water pipes should be covered so as to prevent as much as possible loss of heat by radiation and consequent condensation of the steam. And in this connection it should be noted that there is a great difference in efficiency in the different kinds of pipe covering. Tests have shown that the magnesia plastic and sectional coverings and the asbestos fire felt covering give the best results. ("Journal of the Association of Engineering Societies," January, 1895.) A water separator should be placed in the leader to each engine. It should be large in size and placed as close as possible to the engine.

Steam Consuming Apparatus.

During the past four years, the street railway generator has undergone a radical change. In the spring of 1893, there were installed in this city in the power house of the Cass Avenue & Fair Grounds Ry. Co., then being built, the first large, direct driven generators of the type which has since become so common. Soon after this the Intramural power house, at the World's Fair, was put in operation, containing one generator of the same size as those in St. Louis and another of twice the capacity. Since that time there have been few large power houses built in which direct driven generators have not been installed, and some of the large railway systems have found that economy of operation required a change from the belt, counter-shaft and unit of small size to the large direct-driven generator. At the present time, the West End Railway Co. of Boston, which may be considered the pioneer in this country in electric traction, is changing its central power station, which had originally been equipped with a very complete and elaborate system of belting and countershafting, to a direct-coupled plan.

The first cost of the direct-coupled generator is about 35% more than the belted generator in the 500 K-W. size, which is the largest standard size in which the belted generator is made; but when the expense of the belt, belt-tightening device, and the floor space is taken into account, the direct connected generator will be found the cheaper. Besides obviating the necessity of the costly and cumbersome belt, the direct connected generator offers the following advantages; in large sizes and in connection with large engines it has a much higher efficiency than the belted unit, it requires a small floor space, it aids supervision by bringing the working parts of the engine and generator close together, it reduces danger, it is almost noiseless in operation, and it may be installed in a larger unit than the belt-driven generator, which is limited in size by the width of the belt and pulley which may be employed. The main objection which was urged against the direct connected generator was the fact that the shocks resulting from overhead loads were thrown directly on the engine and that there was none of the cushioning effect that a belt connection might supply. While this is undoubtedly true, the best argument which may be submitted against it is that none of the installations of direct driven generators can trace any trouble to this source. The large, slow speed, multipolar, direct-driven generator has become perhaps the most prominent feature of the modern power house, and while there may be special services which would necessitate a belted arrangement, it is difficult to imagine a power house thoroughly up to date without direct-driven generators.

By varying the number of poles and the number of armature conductors in the construction of a dynamo, the machine may be designed to run at almost any reasonable speed, the slower the speed, however, the greater being the cost of the dynamo. In the matter of speed it is necessary for the dynamo maker and the engine builder to effect some sort of a compromise, because it is not good practice to run such a large engine at too high a speed. The speeds which are most common are 75 revolutions per minute for the 1,500 K-W. dynamo, 80 to 120 revolutions per minute for the 800 K-W. dynamo, and speeds running from this to 150 revolutions per minute for the smaller sizes. These speeds are what would have been considered, four years ago, quite out of the range of the Corliss valve gear, but the makers of this type of engine have risen to the occasion and now there are numbers of large Corliss engines driving generators at speeds up to 100 revolutions per minute and some have even higher speeds than this. Several other types of engines have been adapted to this work and are running quite successfully. Outside of the question of valve gear, most engines made for this work possess the same characteristics; the heavy bed-plate, the solidly constructed fly-wheel, now being made of steel-plate, the wide cross-head, the large connecting rod and the mammoth main bearings.

The choice between horizontal and upright engines is chiefly one of space. The horizontal engine is the cheaper, the simpler, the easier to inspect and the easier to repair. Outside of the advantage of requiring less space, the upright engine has the advantage of less wear on the cylinder, and a more direct strain upon the foundations.

The usual practice in most modern power houses is to install compound engines. Most of these plants are so favorably situated that condensers may be operated in connection with the engines. This is undoubtedly good practice, but in case condensers are not used the cost of fuel must be very high for the gain in compounding to pay for the extra investment. Where power houses are favorably situated on bodies of water, condensing becomes a very simple problem, but in case the power house cannot be built on a body of water, as in this city, for instance, in order to use condensing engines, some sort of arrangement must be designed to cool a quantity of water so that it may be used over and over again for the purpose of condensing the exhaust steam. Devices of this kind have long been in use in the City of San Francisco and in Cuba, and lately several of the large manufacturing companies have put on the market complete apparatus for the purpose of cooling water after it has condensed the exhaust steam so that it may be used again for the same purpose. Besides the gain in power by using condensing engines it is claimed that by the use of this apparatus, actually less water is used than if the steam is exhausted directly into the atmosphere without condensing.

In the use of large direct-connected units a great deal of the economy to be gained depends upon the selecting of the proper sizes of units. The efficiency of a generator will be good when it is operated at more than 75% of its capacity but the efficiency of an engine drops off very rapidly when it is running below its rated load. In order to achieve the best economy from the use of large direct-connected units, the sizes of the different generators should be so proportioned that it is always possible to operate one or more units at their rated capacity. The railway generator as at present built will stand an overload of 50% for several hours without trouble and at a maximum efficiency. This should be taken into account in the estimate of the dynamos required, but it should always be the aim to have at least one idle machine to throw on the line in case of failure of any of the others. The actual size of the unit depends upon the character of travel which the road possesses and the number of cars, and this must be determined for each road independently. In choosing machines, however, standard sizes should always be adopted as this obviates any trouble in obtaining supplies and repair parts.

The railway generator switch board has become standardized to the extent that it consists of a panel for each generator, each panel containing the usual automatic circuit breaker, ammeter, field rheostat, field switch and main switch. Switch boards as now erected usually contain a recording watt-meter and an ammeter which shows the total output of the power house.

The modern method of line construction is to divide the trolley line into sections and connect each section separately to the main bus bars through feeder panels, each of which contains an automatic circuit breaker, an ammeter and a switch. This method confers the advantages that trouble on the line is always indicated on the proper section, and that in case of short circuits on the line, the main circuit breakers are protected by the section circuit breakers and the load is not suddenly thrown off the engines by the opening of the main circuit breakers. Most of the generator and feeder boards are supplied with devices for preventing damage to the station machinery by lightning, but a very simple and effective arrangement is to connect a large water rheostat between the positive bus bar and a good ground. This is either left in circuit continuously with a small current running through it, or is cut into circuit on the approach of a storm.

Besides those machines which are absolute necessities in a power house, there are various devices which may be added to secure convenience and regulation. An overhead crane is installed in the engine room of most of the large modern power houses and adds greatly to the speed with which heavy repairs may be executed. An oiling system of some sort by which the oil is either pumped or flows by gravity to the different bearings obviates the necessity of manual labor in oiling and insures a steady feed at each bearing. A recording steam gage is found useful in checking up the firemen. An air pressure system is beginning to be used in many of the power houses by means of which the carbon dust may be blown out of the armature windings. With this apparatus an armature may be kept thoroughly clean, and the danger lessened of short circuits occurring on account of the collection of carbon dust between its conductors.

A number of power houses operating long lines are now equipped either with boosters or with high voltage dynamos. Long lines usually have a booster constantly in circuit. This machine is automatic in its action and raises the voltage with every increase in the load. Some power houses operate a high voltage dynamo for use on sections which are subject to excessive loads. The feeder boards in this case are equipped with an extra bus bar so that any section may be thrown on the high voltage machine.

While each individual engineer has his own ideas concerning power house construction and while each road building a power house may purchase different apparatus, there is one general design which has been followed in many of the plants recently installed. It might almost be called the Modern Power House. The engine room and boiler room are divided by a brick wall and under different roofs; both are brick buildings covered with an iron truss roof; the boiler room is set on the grade of the street and the engine room 10 or 12 ft. above this grade, the space below the engine room being utilized for the piping and condensers; the engine and boilers are set at right angles to the wall between them, with the engines next to the boiler room so that the piping is made as short as possible and the condensation lessened; the switch board and feeder board are set on the opposite side of the room from the boiler room, so that the length of the dynamo cables is equalized as much as possible. The general features of this design may be summed up as follows: It is compact, to save real estate and buildings and to minimize the number of employees and the superintendence. Large units are used for the sake of economy and to save the number of working parts.

Figures as to cost of operation, collected from some of the large modern power houses, show that less depends upon the refinements of the machinery than upon the condition in which the apparatus is kept and upon the supervision to which it is subjected. The lowest results are about ¾ ct. per K-W. hour, some records running slightly below this, while the results from some of the large stations are as high as 1¼ cts. per K-W. hour. These figures include the cost of coal, water, supplies, repairs and all labor, but do not include anything for taxes, insurance, interest or depreciation. The cost of operation depends largely upon the cost of coal and upon the relation of the average load to the total capacity of the power house, the higher this ratio the less being the cost of operation.

The modern electric railway power house, although it has been developed entirely within the past ten years, represents the thought and the experience of many men. It has been developed carefully, detail by detail, until it is now a work both of reliability and efficiency. No one man and no one company can claim the credit for this achievement, but no class of men hold a stronger claim to recognition than the managers and owners of street railroad properties, who have ever been ready to encourage with their patronage each improvement, who have freely distributed the information gained by their experience, and who even in the most radical departures have ever acted with the courage of their convictions.

Discussion.

Mr. Rossiter.—I ask if any of the members have had occasion to use the storage battery; and if so, with what success?

Mr. Richard McCulloch.—There is one installed somewhere in Pennsylvania, and the Union Traction Co. of Philadelphia have one installed at the end of one of the long lines for the purpose of regulating the voltage at that point; but there is a storage battery in operation in parallel with the dynamos, I think at Easton, Pa.

Mr. B. J. Arnold, Chicago.—During the last year I have had installed in the Chicago Board of Trade plant, as the consulting engineer for that corporation, a battery auxiliary. In my opinion the work of the plant is more severe, if anything, than electric railroad work, because it operates electric elevators in conjunction with constant potential arc and incandescent lights. The elevators take a starting current varying from 0 to 800 amperes, and back again almost instantly, corresponding in abruptness to the load on an electric railway operating three or four cars. In the Board of Trade plant, the battery auxiliary acts as an equalizer and takes the surplus load delivered into the bus bars, when the demand on the line is less than the capacity of the generator, and takes three-quarters of the overload when the pull comes. The result is that with a 75-K-W. generator, running from 7 in the morning until 11 o'clock at night, at its absolutely normal economic load, it produces sufficient energy to operate fifty 2,000 c. p. arc lamps, 600 incandescent lamps, four 30-HP. electric elevators and six 10-I. HP. motors, all running from this one unit, and the unit constantly loaded. That is my experience with the battery, and it is working perfectly satisfactorily, having been running nearly a year and has cost practically nothing for repairs. We have increased the plant by putting in additional plates, because we required additional capacity, but there was no charge for repairs and I am convinced that the battery auxiliary, when there is sufficient lead installed to do the work, is an eminent success for regulating work and economical operation of power stations operating on variable loads. You must get lead enough in the battery to do the work, and having that, you will get good results. I used a battery made by the Electric Storage Battery Co., of Philadelphia, with the Manchester type of positive plate. It makes all the difference in the world if the plate is built for regulation or for slow discharge. This particular type is for regulation and also performs the function of slow discharge, if necessary. The engines and generators stand idle from 11 o'clock at night until 7 in the morning, and the battery does the work through the night. That enables the engine to operate 16 hours a day, with two shifts of labor, at its economic normal load and shut down at night until morning. The same thing can be done in a large number of electric railway plants in this country with success. It is only a question whether the increased economy will be more than the interest on the investment of the cost of the battery. I am installing now three different stations, part railroad, and part lighting, in which it is my idea to use batteries, by which I will find it necessary to put in one-third less capacity of engines and generators than would be otherwise necessary.

Mr. Hawken.—What is the life of the plate under constant use?

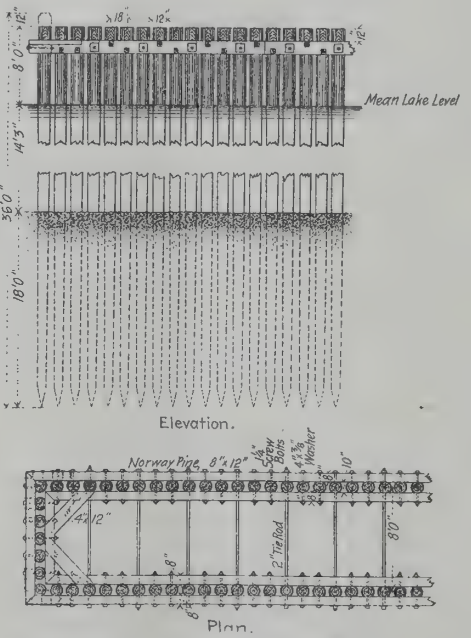
Mr. Arnold.—The plant has been running only about one year, but the depreciation is guaranteed at 7½% per annum. On that basis I figure out a marked economy and feel that we are safe because the company behind the battery will stand up to the guarantee. As a matter of fact it has not cost 1% this year; probably it will cost something next year, and so on each year, but the battery company stands behind it.

We use a booster in the station which consists of a motor generator to charge the batteries, if it ever becomes necessary, while the generators are running on the lines, because then the voltage must remain constant at 125 volts. Then if we wish to charge the batteries we use the auxiliary booster to charge the end or regulating cells, while the shunt winding of the generator is working in parallel with elevators and about 60 of the cells. The elevator service is such as to allow the battery to be charged and discharged in about equal proportions through the day, so that it is practically fully charged at the end of the day's run, and at night if they are slightly discharged we charge them up with the booster by placing the generator end of it in series with the main generator, and at 11 o'clock shut down the engines and run the lights until morning with the batteries. In a railroad power station it would be necessary to use the booster to increase your voltage on your long feeder. If the battery was located at the end of the line you would have to use the booster to overcome the pressure at the battery, or else run a separate high voltage generator.

Mr. Harrington.—I understand from the experience of a large number of railway engineers that on the ordinary size plant, running from 40 to 250 cars where the load constantly changes, by reason of trouble on the line, the standard forms of multipolar generators flash from brush to brush, and cause a great deal of trouble in the commutators of the machine. That is a common occurrence in the Philadelphia Traction Co.'s plant. We have had it in our own plant with both Westinghouse and General Electric machines. The storage battery would be an excellent thing to avoid that form of breakdown or delay, due to the burning of the commutator.

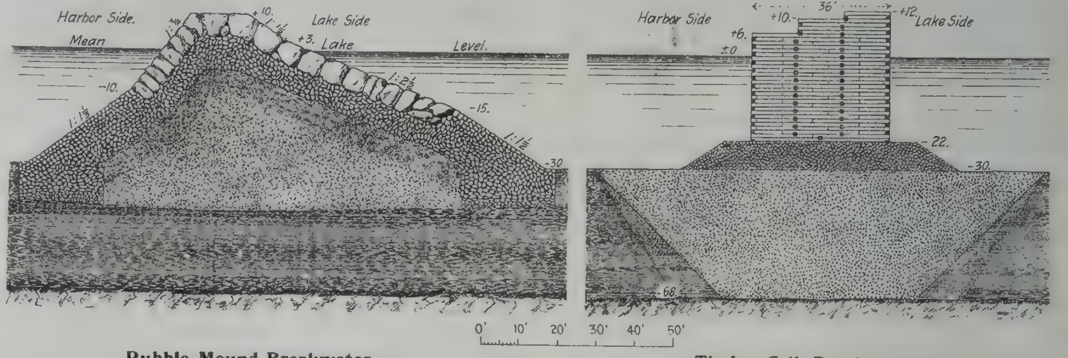
THE BREAKWATER EXTENSION AT BUFFALO, N. Y.

Proposals are now being invited by Major T. W. Symons, Corps of Engineers, U. S. A., for the construction of 12,500 ft. of breakwater extension and for a sand-catch-pier extension at Buffalo, N. Y. At the present time a breakwater, about 8,000 ft. long, lies parallel to and about 3,000 ft. off the shore, at that city, with its northern end and main entrance about opposite the Erie Basin. This breakwater lies in water about 31 ft. deep and encloses a narrow harbor with about 20 ft. of water. It is now proposed to extend this structure directly south to Stony Point; with a middle and south entrance, and with the breakwater constructed partly of rubble mound work and partly of timber crib.



Sand-Catch Pier Extension, of Buffalo Harbor.

The illustrations, taken from the government specifications, show the general construction of both the rubble and timber work; and show it so plainly that little explanation is needed. The length of the rubble mound will be about 5,000 ft. and that of the timber crib about 7,500 ft.



Rubble Mound Breakwater.

Timber Crib Breakwater.

TYPICAL CROSS SECTION OF NEW BREAKWATER FOR THE HARBOR OF BUFFALO, N. Y.

The rubble mound breakwater will consist of a core of gravel, or other specified material, covered with ordinary rubble stone and capped by large stone. It will extend 10 ft. above mean lake level and have a top width of 15 ft. with a harbor slope of 1 on 1⅓, from the lake bottom to 10 ft. below mean lake level, and a slope of 1 on ¾ from that point to the top. On the lake side the slopes will be 1 on 1½ from the lake bottom to a point 15 ft. below lake level; 1 on 2½ from this point to 3 ft. above lake level, and 1 on 1½ from the latter point to the top. The gravel core is to have a base of 100 ft. and a general height of 26 ft. above the lake bottom when the material has settled. The rubble stone used is to be as nearly cubical as possible, and at least one-fourth of the volume must be in pieces of 300 lbs. and over in weight. The stone will be dumped from scows on lines established by range-piles and buoys, and the total amount required is estimated at 320,000 cu. yds. The amount of gravel required is about 640,000 cu. yds., scow measure. The capping stones must not be less than 2 ft. thick, and delivered in blocks weighing from 3 to 10 tons and upward; at least one-half the stones must weigh 5 tons and none less than 3 tons.

For the timber cribwork a trench, 50 ft. wide at the rock bottom, must first be excavated through the soft material. On parts of the location the water is 30 ft. deep, and the mud deposit averages 38 ft. in thickness. The rock along the greater length of the pier lies from 59 to 77 ft. below the water surface, and the bottom deposit varies from 27 to 49 ft. in depth. The trench excavated must be backfilled to the level of the lake bottom with gravel, or other acceptable material, as a stable foundation for the cribwork. Upon this gravel will be deposited a layer of rubble stone, 50 ft. wide on top and 22 ft. below mean lake level. At least 10 days must be allowed for the settlement of the trench filling before the rubble foundation is put in place. The amount of this rubble is estimated at 126,000 cu. yds.

The timber cribs will be 36 ft. wide and 22 ft. high, with the tops, as sunk, at mean lake level. The three top courses and the upright posts in each crib will be made of white pine, and the remainder of hemlock timber, with the timbers varying in length from 10 to 36 ft. Each crib must be 60 ft. long, or as much longer as the contractor can make it, under the specified conditions. Each crib will be built with a grillage bottom, solid outer walls and tiers of cross and longitudinal stringers, and finally filled with stone and solidly decked over, as indicated in the cut.

A continuous timber superstructure is to be built over the cribs, 12 ft. high on the lake side for a width of 12 ft.; 10 ft. high in the middle for a width of 12 ft., and 6 ft. high on the harbor side for 12 ft. in width. This superstructure must be built of white pine sticks, 12 ins. square and from 10 to 36 ft. long, bolted and drift-bolted and made with solid outer walls and cross and longitudinal stringers. The superstructure is also to be completely filled with stone and decked over with white pine planking.

The sand-catch pier will connect the shore with the established pier-head line, and will be made up of two rows of close piling, 8 ft. apart between centers, and secured by waling strips 8 × 12 ins. along the inner and outer faces of each row. These rows of piling will be joined by iron tie-rods. This work is under the charge of Major T. W. Symons, Corps of Engineers, U. S. A., and proposals are to be received until Nov. 30.

THE MOSKOWITZ INDEPENDENT SYSTEM OF CAR LIGHTING BY ELECTRICITY.

The application of electric lighting to railway cars has many desirable features to recommend it, and numerous experimental and actual applications have been made on railways in this and other countries, but in many cases the cost of operation has been such as to deter the railway companies from introducing this means of lighting, except on a limited number of high-class trains. In the attempt to devise a commercially practicable system, the most encouraging direction has been that of making each car independent of the others in the train, and various patents have been taken out on methods of driving the generator from one of the car axles. A system of this kind, which appears to possess many practical advantages, is that invented by Mr. Morris Moskowitz, which has been under experimental development for some years. The system comprises a dynamo driven from one of the car axles, a storage battery in two sets, a switchboard and a lamp circuit in the car. It is entirely automatic, requiring no special attendant, and only requiring inspection at intervals of about a week. The system is now being introduced by the National Electric Car Lighting Co., 30 Broad St., New York city, and we are indebted to Mr. Max E. Schmidt, M. Am. Soc. C. E., of that company, for blueprints and information used in this article.

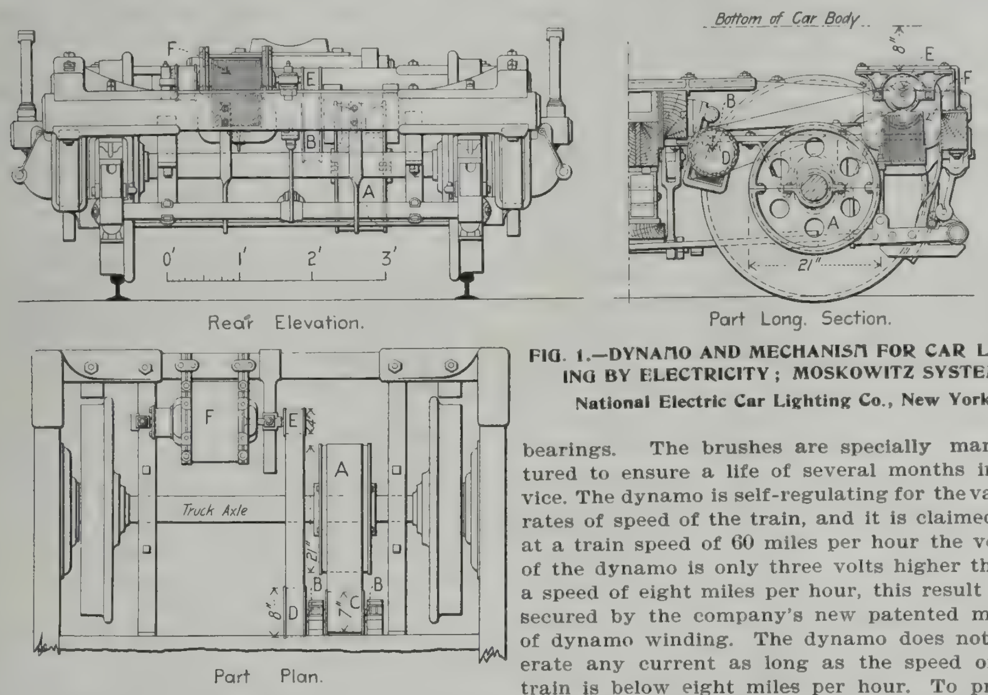


FIG. 1.—DYNAMO AND MECHANISM FOR CAR LIGHTING BY ELECTRICITY; MOSKOWITZ SYSTEM.
National Electric Car Lighting Co., New York.

The general arrangement of the apparatus is shown in Fig. 1. On the truck axle is clamped a split pulley, A, which is made of wood specially prepared to be impervious to atmospheric effects, and weighing 35 lbs. The cast-steel countershaft B carries two pulleys, C and D, the former of which is driven by a belt from the main pulley A, while a belt from the latter drives the pulley E, on the dynamo shaft. The countershaft B is carried in spring-cushioned bearings on the inner side of the transverse member of the truck frame, near the king bolt, and the weight of shaft and pullies is 80 lbs. The belts are of a double thickness of leather specially prepared so as not to be liable to be affected by changes of weather or by dampness, snow or ice. The dynamo, which weighs 300 lbs., is attached to the outer end of the truck frame, so that it can be readily inspected, it is enclosed in a dust-proof and weather-proof steel cylindrical casing. The vibrations from the car axle are taken up by a pair of powerful spiral springs, attached to the countershaft B. The bearings of this shaft are interchangeable, and are lubricated about once a week with a heavy lubricating grease. Oil wells (with a supply for one week) and several self-oiling rings are attached to the dynamo shaft bearings. The brushes are specially manufactured to ensure a life of several months in service. The dynamo is self-regulating for the varying rates of speed of the train, and it is claimed that at a train speed of 60 miles per hour the voltage of the dynamo is only three volts higher than at a speed of eight miles per hour, this result being secured by the company's new patented method of dynamo winding. The dynamo does not generate any current as long as the speed of the train is below eight miles per hour. To provide for the movement of the car in opposite directions, it is necessary that the dynamo should generate the current in either direction, and to effect this the electric poles are automatically changed in accordance with the direction in which the car is moving, so that the dynamo generates current at all times when the speed exceeds eight miles per hour, no matter in which direction the car is moving. This pole changing device is one of the special features of the Moskowitz system.

All the time the train is running, and also when the train is at rest or moving at slow speed, as in stopping or starting at stations, the current for the lights is supplied by storage batteries of a special type, owned by this company. These batteries are carried in two wooden boxes under the car, and while one set is furnishing light the other is disconnected and is being charged from the dynamo. If the batteries are first charged sufficiently to furnish light for six hours, the plant will furnish light for from 10 to 15 hours every night, as long as the car is kept running. When put on the sidetrack the batteries are shut off, and the stored batteries are ready to furnish light at a moment's notice.

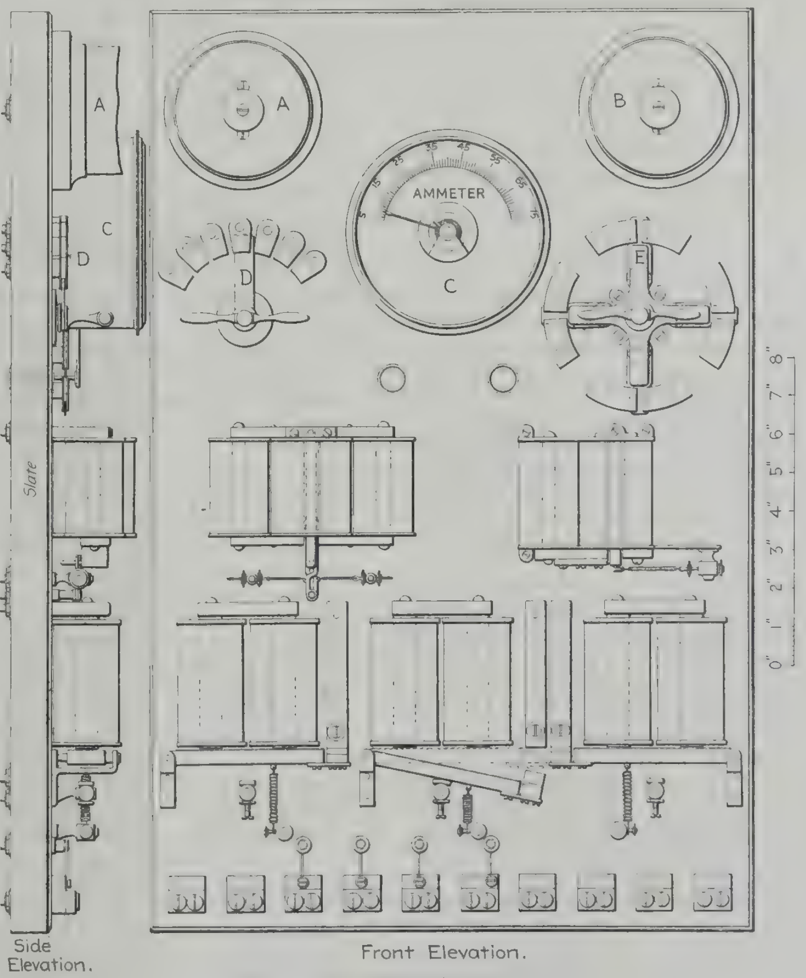

FIG. 2.—SWITCHBOARD FOR CAR.

The switchboard in the car is shown in Fig. 2, and includes the electro-magnetic devices for charging the electric poles automatically when the motion of the car is reversed, and also several other novel automatic devices. The main switch, A, controls all the circuits, and is kept closed, while the dynamo is generating current. The switch of the main light circuit is at B; the ammeter, C, shows the quantity of current generated, and D is a small resistance coil for the light circuit, which can be used if desired, but is not necessary. The main circuit between the dynamo and the storage battery is automatically opened and closed by means of the difference of pressure between them. The twelve-point switch, E, controls the connections between the two sets of storage batteries. When the battery that is furnishing light is exhausted, the switch is turned, throwing the charged battery into service and connecting the exhausted battery with the dynamo for re-charging. The switchboard can be attended to by a brakeman. The lighting equipment for an ordinary passenger car is 14 incandescent lights of 16 c. p., 12 of these (in four three-light groups in the roof, or else separately alongside the edge of the monitor roof) being in the body of the car and one over each platform. Owing to the use of the batteries the light is maintained quite steadily, there being no direct current from the dynamo to the light circuit.

One car equipped with this system is now running on the Pennsylvania R. R., between New York and Philadelphia. This car has 15 lights; 12 in the main part of the car, 1 in the hood over each platform, and 1 at the switchboard in the brakeman's closet; either of the last three lights can be turned on or off at will, and the last named is removable, with flexible cord attachment so that it can be used under the car when oiling or inspecting the dynamo. The car is an ordinary Pennsylvania R. R. day car, with a wide shallow monitor roof, the lamps being placed along the lower edge of the monitor roof. The lamps have short bulbs and filaments, and the bulbs are set in ornamental glass holders. They are 32-ampere lamps of 16 c. p. The batteries are in a box under the car, and the two sets comprise 32 cells weighing 45 lbs. each, or 1,440 lbs. in all. The cells have watertight rubber covers, and the only loss of the acid is by evaporation, which is very slight. The batteries will supply the car with light for 15 hours. This car is run on the westbound express train leaving New York at 6 p. m., and arriving at Philadelphia at 8.30 p. m., making only two regular stops. The return trip is made with the eastbound "owl train," leaving Philadelphia at 12.01 a. m. (midnight) and reaching New York at 3.53 a. m.; this train makes 26 regular stops and 5 extra stops on order. The westbound run tests the efficiency of the mechanism, while the eastbound run tests the electrical efficiency in securing steadiness of light. A chair car for the Atchison, Topeka & Santa Fe R. R., to run between Chicago and Kansas City, is now being equipped with this lighting system at the Newark works of the company.

The principal claims made for the Moskowitz system are as follows: High efficiency, moderate first cost, small operating expense, simplicity of design, easy and infrequent inspection, and the absence of skilled or special attendants on the cars.

◆

A TEST OF SLOW-BURNING WOOD AND PLASTER CONSTRUCTION.

An interesting test of a partially fireproof construction for halls, stairways, partitions, etc., manufactured by the New Jersey Adamant Co., of Harrison, N. J., took place in a lot in the rear of No. 112 Ocean Ave., Jersey City, on Oct. 26. A member of the staff of this journal was present by invitation. The construction consists in the substitution for ordinary lath and plaster of a "plaster board" made of plaster of paris cast around a core of wood excelsior. The boards are made 48 × 27 ins. in size, by ⅝-in. thick. Two of the four edges are rabbeted for an inch, to allow for overlap of adjoining boards, and the other two edges have cast in them a strip of burlap, which, when placed in the rabbeted joint and caused to adhere by running in liquid plaster, makes a joint which is not liable to crack. In applying the construction to the studding of a partition, the studs being placed 16 ins. apart as is usual, strips of plaster board of the same width as the studs are nailed upon their inside surfaces, then horizontal strips are placed across the space between the studs at intervals of 2 ft., and the whole is then enclosed between plaster boards nailed on both sides of the partition with large-headed nails.

For the purposes of the test a furnace was built of 3 × 4-in. wooden studding and plaster boards, its size and shape being that of a 4 ft. cube. One end of the cube was left open, and at the other was built a chimney 20 ins. square inside and 12 ft. high, of the same construction. The whole structure was plastered over, inside and out, with a thin coat of hard finish. The furnace, after being dried by a slow fire for a week, was half-filled with firewood, which had been wet with kerosene, and the fire was lighted at 2:30 p. m. About a cord of wood was used in all during the test, which lasted an hour and a half, the fire being replenished with wood at frequent intervals. Every effort was made to get as hot a fire as possible. During part of the test the open side of the furnace was partly closed by a wooden door protected by plaster boards, but as it checked the draft to some extent the fire was apparently no hotter than when the door was left off. The fire seemed to have no effect whatever on the structure for the first half hour, except to make a network of fine cracks all over the plastered wall of the inside of the furnace chamber. One hour after starting a crack appeared at the corner of the inside of the furnace and the chimney, but none of the plaster board fell off, and the studding was not exposed more than the thickness of the crack. At 4 p. m. or 1½ hours after starting, the first serious damage to the structure was observed. A portion of the plaster board on the inner side of the roof of the furnace fell in, exposing one side of the studding. The other three sides being protected by the plaster board, however, the studs burned very slowly, and they would probably have lasted half an hour longer if exposed to the same fire, before burning through to such an extent as to drop the roof, but the test was not continued further as all the firewood on hand had been used. It should be said that the inner side of the roof was supported to some extent by thin sheet iron strips besides being nailed to the studs. On the whole the test was a highly satisfactory one, and the resistance of the plaster board to a strong fire for an hour and a half was remarkable, when we consider that plaster of paris alone when exposed to such a fire for 15 minutes becomes so friable as to be easily broken by the fingers.

The construction tested was patented Feb. 12, 1895, by Mr. Jas. D. Baker, of Montreal, Canada. It is manufactured by the New Jersey Adamant Co., Harrison, N.J. (J. Wesley Dey, president); and by the Hudson Plaster Board Co., 130 Fulton St., New York city.

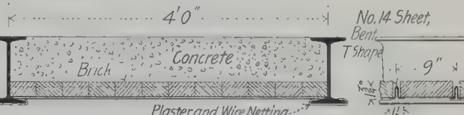
TEST OF THE RAPP FIREPROOF FLOOR CONSTRUCTION.

The fourth test in the series of tests of fireproof floors, which is being conducted by the Department of Buildings of New York city, was made at 68th St. and Avenue A, on Oct. 26. The test was made in a similar manner to those described in our issues of Sept. 17 and Oct. 1, by making a section of the floor serve as a roof to a brick building 15 ft. long × 12 ft. wide, inside measurement, and 12 ft. high. A floor of grate bars was placed near the bottom and cord wood piled on it. A small chimney was built at each corner of the roof. The fire was started at 10 a. m., and was kept up for five hours, when the door was opened and the roof suddenly cooled by a stream of water from a fire engine. The floor tested was Mr. J. W. Rapp's patent, built by the Rapp Sheet Metal Works, Nos. 309-319 East 94th St. Its construction is shown in the accompanying cut. The I-beams 10 ins. in depth are placed 4 ft. apart between centers, and the lower flanges support a series of light bearers made by bending sheet iron of No. 14 gage into a T-shape, 1¾ ins. high × 1½ ins. wide. These bearers are placed 9 ins. apart, being held in position by light sheet iron strips or separators, and they support a flooring of common red brick, as shown in the cut. On top of the brick is laid a bed of concrete, made of 1 part of Portland cement and 8 parts of cinders, to the level of the top of the I-beams. The under side of the floor was plastered with a thin coating of hard finish plaster.



Fireproof Floor Construction. Patented by J. W. Rapp, New York.

Within an hour from the starting of the test the temperature under the floor had reached 1,800° F., as shown by the Uehling & Steinbart pyrometer, when a piece of the plaster fell on the platinum tube of the pyrometer and damaged it so that it could no longer be used. Shortly afterwards a piece of copper wire placed in the building was melted, indicating a temperature of from 1,900 to 2,000° F. The fire was maintained at a high heat by frequent additions of cord wood, until 3 p. m. One of the panels of the floor was loaded with pig iron to 150 lbs. per sq. ft. Readings of deflection were made by an engineer's level from time to time. At noon the deflection was 1.35 ins.; at 12:45 p. m., 1.72 ins., and at 3 p. m., 2⅜ ins. After throwing the stream of water on the under side of the floor it was found that the iron strips holding the brick floor had sagged two or three inches, and some of the brick had fallen out in the center, but the bed of concrete remained intact and apparently uninjured.

The whole floor showed a maximum deflection of 2⅜ ins. when the heat was the greatest, but as when cooled the deflection was found to be only 1.2 ins., the maximum deflection was probably due to the lower flanges of the beams being heated more than the top flanges. Apparently, however, the lower flanges were not heated to such a degree as to be seriously weakened, for if this had occurred they would have stretched under the load and would not have gone back when cool.

INDURITE, OR NAVAL SMOKELESS POWDER.

In an interesting address on the development of smokeless powder, delivered before the Washington Section of the American Chemical Society, Mr. Charles E. Munroe describes the result of his own experiments in producing a smokeless powder for the United States Navy. He recognized at the outset the impossibility of obtaining absolute uniformity and constancy of composition in physical mixtures like gun powder and determined to produce a powder which should consist of a single substance in a state of chemical purity. This had never been done before, and has not been done since, so far as Mr. Munroe can ascertain.

He began by purifying dried pulped military gun-cotton by extracting it with hot methyl alcohol, in a continuous extractor, and then drying the insoluble cellulose nitrate remaining. The highly nitrated cellulose was then mixed with a quantity of mononitro-benzine, which scarcely affected its appearance and did not alter its powdered form. This powder was then incorporated upon a grinder by which it was colloidized and converted into a dark translucent mass resembling india rubber. This sheet was cut into flat strips or grains, or it was pressed through a spaghetti machine into either solid or perforated cords of required dimensions, which were then cut into grains. The granulated explosive was then immersed in water, boiling under the atmospheric pressure, by which the nitro-benzine was carried off and the cellulose nitrate was indurated; the mass became light yellow to gray in color and as dense and hard as ivory. It was by this physical change in state, varied within limits by the press, that the material was modified so as to pass from a violent rupturing explosive to a slow-burning propellant. This is the powder called Indurite by Mr. Munroe and popularly known as naval smokeless powder.

On testing, this powder gave remarkably regular pressures and uniform velocities. The powder called for by the naval authorities was required to give a velocity of 2,000 ft. per second, with but 15 tons pressure to the square inch. In two successive rounds, with a 6-in. rapid-fire gun, using 26 lbs. of Indurite and a 100-lb. projectile, the pressures were 13.96 and 13.93 tons and the velocities 2,469 and 2,456 ft. per second respectively. This powder stored for six months, part of the time being very hot, showed absolutely no change in a firing test. All smokeless powders, except Indurite, are mixtures of one or more of the cellulose nitrates, or admixtures of these bodies, with nitro-glycerine, or some other oxidizing agent, like varium nitrate, and a restrainer; and all are condensed or hardened into a rubber-like or celluloid-like form, and are expected to undergo combustion at a moderate and regular rate.

In the same paper Mr. Munroe reviews the history of gun powders from A. D. 1346, and that of smokeless powder from 1845. Any of our readers especially interested in the subject will do well to obtain a copy of Mr. Munroe's paper which may be obtained from the Chemical Publishing Co., Easton, Pa.

AN ENGLISH VIEW OF AMERICAN COMPETITION.

American competition in the cycle trade is announced. A Birmingham correspondent who has business connections on the Continent has recently been staying in Berlin, and on his way visited a few Dutch towns. Whilst traveling, he was much struck with the rapid and increasing sales of American cycles in Germany and Holland, and in Berlin especially a very large number of American machines is to be seen, whereas six months ago they were comparatively speaking unknown. He was told that at nearly all the cycle depots the sales of American machines were on the increase. The correspondent continues: "If wooden rims and very light machines are the demand on the Continent, it surely behoves those engaged in the cycle industry to go with the times." A friend—the representative of a large house dealing in agricultural implements—once told him, and it is more true now than ever, WEATHERTABLE FOR SEPTEMBER, 1896. (Furnished to Engineering News by the Department of Agriculture.)

that the American makers of agricultural implements had almost completely ousted the English manufacturers of reapers, binders, etc., in Germany, Russia, Austria and Hungary. The English firms would not listen to the advice tendered them by their agents in great cities and centers, and would not adopt the methods of the Yankee makers, with the consequence that orders were lost, and the trade went to the States. It is to be hoped that this will not be the case with the cycle indusry.—The Engineer (London).

ANNUAL MEETING OF THE AMERICAN STREET RAILWAY ASSOCIATION AT ST. LOUIS, MO.

The fifteenth annual meeting of this Association was held Oct. 20 to 23, at St. Louis, Mo. At the opening meeting, with the President, Mr. H. M. Littell, in the chair, the proceedings were opened with prayer by Rev. P. G. Robert, and Mr. Charles Nagel, Acting Mayor of St. Louis, delivered an address of welcome, after which the president delivered the annual address. In his remarks he dealt mainly with the growing disposition of state and municipal governments to increase the burden of taxation imposed upon street railway companies, which is due largely to a popular prejudice against corporations, and the only remedy for which is a gradual enlightening of the public mind and the cultivation of a broad and conciliatory management by the roads. Another severe strain is that of the high penalties imposed by the courts upon the companies for the negligence of their employees. Remedies for this are the education of the public and the employees to the exercise of more care in the use of the streets and the handling of the cars. He closed his address by referring to the great public importance of street railways.

The report of the Executive Committee was then presented, and showed that the membership in October, 1895, was 173 companies; 8 new companies had joined the association; 3 had become consolidated; 1 company had withdrawn, and 13 companies had been dropped for nonpayment of dues, leaving the present membership 164 companies. At the beginning of the present fiscal year the Association was in debt $6,000; this indebtedness has been cancelled, and the income during the forthcoming year will be about $6,500, which will enable the Secretary to enlarge the scope of the work of the Association. It is proposed to issue a monthly bulletin containing information of value to the members.

The report of the Secretary and Treasurer was next read, and the following is a summary of the figures there given:

Receipts	$12,044
Expenses	10,278
Balance	$1,766
Liabilities	381
Net assets	$2,530

The first paper on the list was that by Mr. M. K Bowen, Superintendent Chicago City Railway Co., on "Track and Track Joints, Construction, Maintenance and Bending," an abstract of which, with the discussion upon it, is given in another column.

At the meeting on Oct. 21 the first paper presented was one by Mr. John N. Akarman (Worcester Consolidated St. Ry.), on "Street Car Trucks," and this was followed by a paper on "The Modern Power House," by Mr. Richard McCulloch (Citizens' Ry. and St. Louis Ry.). Abstracts of both of these are published on another page of this issue. A paper on "How Can the Revenues of Street Railways be Increased," was then read by Mr. G. Densmore Wyman (Milwaukee St. Ry.), in which he took into consideration the collection of fares, methods of registering fares, transfers, the use of tickets or cash fares, attractions along the line of the road, etc. He considered that motormen should have some experience in the repair shops before taking charge of cars. After the appointment of a nominating committee the meeting adjourned.

On Oct. 22 the greater part of the morning was spent in examining the extensive exhibit made by manufacturers of and dealers in street railway supplies. When the meeting was called to order a paper by Mr. B. Willard (New Orleans City & Lake Ry.) on "Modern Overhead Electric Construction," was read in the absence of the author. An abstract of this is also printed separately.

The committee on nominations then submitted its report, and officers for the ensuing year were elected as follows:

President, Robert McCulloch, Vice-President and General Manager, Cass Ave. & Fair Grounds Ry., St. Louis, Mo.; First Vice-President, Charles S. Sergeant, General Manager, West End St. Ry. Co., Boston, Mass.; Second Vice-President, D .B. Dyer, President, Augusta Ry. Co., Augusta, Ga.; Third Vice-President, C. F. Holmes, General Manager, Metropolitan St. Ry. Co., Kansas City, Mo.; Executive Committee, H. M. Littell, Vice-President and General Manager, Metropolitan St. Ry. Co., New York city; H. P. Bradford, General Manager, Cincinnati Inclined Plane Ry. Co., Cincinnati, O.; Charles H. Smith, Superintendent, Troy City Ry. Co., Troy, N. Y.; Harry Scullin, Vice-President and General Manager, Union Depot Ry. Co., St. Louis, Mo.; George B. Hippee, General Manager, Des Moines City Ry. Co., Des Moines, Ia.; Secretary and Treasurer, Thomas C. Penington, Treasurer, Chicago City Ry. Co., Chicago, Ill.

The report of the committee recommending Niagara Falls, N. Y., as the place for the next meeting, in 1897, was also adopted. On motion of Mr. I. A. McCormack (Gen. Supt., Brooklyn Heights Ry.) a committee of five members was appointed to consider the propriety of the association adopting a standard code of rules and regulations for the government of employees, similar to that in use on steam railways. The annual banquet was held Thursday evening. At the meeting on Oct. 23 the first business was the reading of a paper on "The Selection and Management of Employees," by Mr. W. F. Kelly (Columbus St. Ry.), in which particular stress was laid upon the necessity of exercising greater care in the employment of men, of properly educating and instructing them, and of properly treating them. This paper brought out an extended discussion, in which reference was made to the provisions now made by several companies for the comfort and convenience of the men, in the way of reading rooms, waiting rooms, baths, gymnasiums, etc. It was also pointed out that punishment by suspension is liable to cause much ill feeling by making the man's family suffer for the period of his enforced idleness, besides tending to injure his character.

After the passing of resolutions of thanks to various persons and associations the meeting adjourned. The convention was well attended, over 1,000 persons being present, and a very good set of papers was presented, but the discussions were not very extended for the reason that the meeting room, in the corner of the Auditorium, was not heated, and the members were therefore not anxious to remain long to talk.

ANNUAL CONVENTION OF THE ASSOCIATION OF RAILWAY SUPERINTENDENTS OF BRIDGES AND BUILDINGS.

The sixth annual convention of the Association was held at Chicago, Ill., Oct. 20, 21, and 22, 1896, and a programme of twelve special committee reports was presented for discussion. This programme was decreased considerably, however, by the failure of three of the committees to present reports, a request by a fourth for more time, and individual reports by a single member only of two other committees. The reports actually presented were as follows: "Different Methods of Numbering Bridges;" "Drawbridge Ends, Methods of Locking;" "Protection of Trestles from Fire;" "Local Stations at Small Towns and Villages;" "Tanks, Frost-Proofing, Size, Style and Details of Construction;" "Best and Uniform System of Report Blanks for Bridge and Building Department;" "Mechanical Action and Resultant Effects of Motive Power at High Speeds Upon Railway Structures;" "Best and Most Economical Railway Track Pile Driver;" "Span Limits for Different Classes of Iron Bridges." Five of these reports were printed and distributed in advance of the convention, and the others were read from the manuscript.

During the opening session the time was taken up with the usual addresses, reports of officers and other routine business. The secretary's report showed the financial condition of the society to be good, there being a balance in hand above all expenditures of $233. The total membership of the society is 221, of which, however, only about 30 members were present at the convention. Applications for membership from 20 new men were received and the applicants elected. Two members were lost by death during the year.

The first work of the second session was the appointing of committees on nominations, auditing, resolutions, obituary and subjects for discussion. The reports of the special committees were then read in the order outlined above, but as, according to the usual practice, their discussion was postponed until the second day, they will be considered in the proceedings of that day. The review and discussion of the committee reports presented at the preceding year's convention was the next order of business. These reports have already been printed in full in the Association's proceedings for 1895, and in abstract in Engineering News of Oct. 24, 1895, and need not be repeated here. Only three of these reports, viz., "Methods and Special Appliances for Building Temporary Trestles Over Washouts and Burnouts;" "Best Method of Erecting Plate Girder Bridges," and "Sand Driers, Elevators and Methods of Supplying Sand to Locomotives," were discussed at any length, and this discussion consisted largely of a relation of the practice of different members.

In regard to repairing washouts and burnouts, Mr. W. M. Noon (D., S. S. & Atl.) stated that his practice was to keep always a large stock of timber on hand. Immediately a burnout was reported he examined his records to ascertain the character, dimensions, etc., of the destroyed structure and from this knowledge he selected and loaded his material. The force was divided into separate crews to carry out the following duties: Clearing up wreckage; sawing off old piles; unloading material; getting material in place by push-cars; framing; erecting; track construction. Mr. James H. Travis (Ill. Cent.) stated that the main supply yard of the road was at Chicago, where material was always on hand for a 400-ft. or 500-ft. opening. His first concern after getting his material under way was to establish a good commissary, if the work was likely to last more than 24 hours. Work on the repairs was divided into two shifts, one gang commencing very early in the morning and continuing until noon, the other working from noon until 8 or 10 p. m. Pile and frame bents were used to fill the break, the bents being placed 14 ft. c. to c., the caps were 12 × 12-in. timbers and the stringers 12 × 16-in. timbers. When possible piles are always used. The pile driver has a reach of 26 ft. and in first work the pile bents are placed that distance apart, but after trains are running a bent is placed midway between each pair of those first erected. He considered it advisable to work only by daylight when possible, but if work was done by night he preferred a bonfire for lighting to anything else and always carried two or three car loads of wood for that purpose.

Except for difference in detail the methods described by other members varied but little from those of Mr. Noon and Mr. Travis, and those described in the committee report. The discussion on both the other reports mentioned above was brief and added but little new information. The concensus of opinion seemed to be in favor of erecting plate girders on false works along side of the old structure and sliding them into place when this could be done conveniently, but it was considered that in almost every case the best method would vary with the local conditions. As an example of rapid plate girder erection, Mr. M. Riney (Chicago & Northwestern) mentioned the Merrimac River bridge. This work was described in Engineering News, July 9, 1896. In relation to sand driers, Mr. Walter G. Berg (Lehigh Valley) called attention to the increased use of compressed air for elevating the sand. He considered the practice good in large plants, but doubted the advantage of its extension to small sand houses.

Wednesday's Sessions.

The second day's work of the convention was devoted to the discussion of the special committee reports read the first day. The first report considered was that of the committee on "Different Methods of Numbering Bridges." The report brought out the fact that a great variety of practice existed in regard to numbering openings in the track. Some railways numbered all openings, some only those above a certain length; some numbered bridges but not culverts, and some did not number anything. A similar variety of practice was shown in the systems of numbering preferred, but generally they were all modifications of the "consecutive" and the "mileage" systems. In the consecutive system the structures were numbered consecutively from unity upward, beginning at one end of the road, and this method was recommended as best by the report. In the mileage system the structure received the number of the mile of line on which it was located with affix letters or fractions for second, third, fourth, and additional structures on that mile. The gist of the report was that bridges and culverts should be numbered and that the consecutive system was preferable.

Mr. Walter G. Berg (Lehigh Valley) opened the discussion by asserting his preference for the mileage system, which he considered more easily comprehended by all classes of employees, and more elastic to admit of the addition and throwing out of structures. Mr. Onward Bates (C., M. & St. P.) stated that he numbered consecutively by divisions, each division having an initial letter. Everything above 6-ft. span was classed as a bridge, and all openings covered by ballast as culverts. Bridges received even numbers and culverts odd numbers, but when a structure was changed from one class to the other it retained its original number. He preferred the mileage system but did not deem it advisable to renumber the 16,000 openings on his line for the advantage. For bridges he used a numbered board, 2 × 12 ins., which was nailed to the end tie, but for culverts the board was fastened to a near-by fence post or telegraph pole where it could be easily seen from a hand-car. Mr. A. McNab (Chic. & W. Mich.) stated that he used the mileage system, with prefix letters to denote branch lines. The number post was driven into the ground 4 ft. or 5 ft. away from the bridge. Besides mile posts his road had station numbers every 500 ft. Cattle guards and culverts were designated as being so many feet from station. Mr. J. H. Travis (Ill. Cent.) stated that all structures were numbered, the numbering being by divisions and by the mileage system. For example, a structure, 565 ft. beyond the 50th mile of division A would be numbered A 50 + 565. The number posts for bridges were sawed diagonally, or from corner to corner, from 6 × 8-in. ties, and painted white with black letters. For culverts a similarly painted 6 × 6-in. cypress post was used. Mr. J. H. Cummin (Long Island) stated that he numbered all bridges consecutively from 1 to 300, all culverts consecutively from 300 upward, and used enameled iron number plates. Mr. Aaron S. Markley (Chic. & Ea. Ill.) preferred the mileage system and used it. Mr. W. M. Noon (D., S. S. & Atl.) used the consecutive system and preferred it to the mileage. Mr. J. O. Olmstead (Cent. Vt.) stated that he numbered all openings over 6-ft. span with 10 × 16-in. board placed on a post 8 ft. from the track. The system was the consecutive but he considered the mileage system preferable. Mr. N. W. Thompson (P., Ft. W. & Chic.) stated that he numbered all openings, but put number plates only on those over 24-in. span. He numbered consecutively, and affixed a letter to the number when additions were made. A cast-iron number plate 2 ft. long and with 6-in. figures, set on a 1½-in. gas pipe post was used. He considered the mileage system to be the better. Mr. W. A. McGonagle (Dul. & Iron Range) stated that he numbered all openings, using the mileage system with affixed letter for second and additional openings, and in case the structure was on a branch he prefixed to the number an initial letter designating that branch. The discussion showed that the majority of opinion was against the preference of the committee report for the consecutive system.

Mr. C. C. Mallard (So. Pac.), a member of the committee on "Draw Bridge and Turntable Ends, Methods of Locking," presented a short report on the subject, the committee as a whole not reporting. The report gave illustrations of a number of such constructions for swing bridges, all of which were of common form, but made no recommendations. In the discussion which followed attention was turned entirely to the locking devices for turntable ends. The principal objection to the ordinary locks was that they could be snapped into place while the table was in motion, thus subjecting it to injurious shocks. A majority of those discussing this point seemed of the opinion that the only good lock was one that could not be closed until the table had been brought to a full stop.

The committee on "Protection of Trestles from Fire" presented no report, but Mr. G. W. Hinman (L. & N.), one of the members, described a system of iron plate protection used by himself with success. In this construction the caps and rail joints were covered with No. 20 galvanized iron plates having their edges lapped down at angles of 45°. With this construction he adopted also the usual precaution of clearing away the grass and weeds from the feet of the trestle bents. In the discussion which followed Mr. Wm. O. Eggleston (Chic. & Erie) stated that he used an iron plate protection, but all of the others, eight in number, who made remarks, stated that their only protection consisted in clearing away grass and weeds and providing water barrels and occasionally watchmen.

The next report was that of the committee on "Local Stations for Small Towns and Villages," and it consisted of 39 plans of actual stations of this type constructed by various railways. The discussion turned upon the best form of platform construction and the advisability of having separate waiting rooms for men and women. For platforms, plank was the most common material, but brick, cinders, stone dust and concrete were also used quite extensively. The general opinion was that the platform should be at rail level or at most only a few inches above the rail. In regard to the number of waiting rooms Mr. J. H. Cummin (Long Island), spoke strongly in favor of the single "combination" waiting room, and stated that this form had been adopted on the Long Island R. R. In these stations the agent's room was separated from the main room by a wire netting or sometimes grill work, so that he could see everything that took place. Smoking and lounging were forbidden. Several other members stated that they used both combination and separate waiting rooms, the choice depending upon the size and conditions. Mr. J. H. Travis (Ill. Cent.) stated that in the Southern states at least two waiting rooms were required by custom and in some states by law, one for colored and another for white people.

The committee report on "Tanks; Frost-proofing, Size, Style and Construction" was next considered, and was substantially as follows:

> After considerable correspondence with different members of this association we find that most roads use the standard 16 × 24-ft. tank, with a capacity of 50,000 gallons. These tanks are placed on various styles of substructures, some of which are oak, others pine; but the most up-to-date substructure is that made of steel, which we find quite a number of roads have adopted or are about to adopt. As for frost-proofing, some roads box up their pipes with brick-work, others use lumber, which is considerably cheaper and answers the purpose nearly as well. Where it is exceedingly cold during the winter it is good policy to house in the substructure and keep a fire under the tank, allowing the smoke and heat to pass through a pipe near the valve in tank and out through the roof of the tank. In this case it may be necessary to ceil over the upper joists in order to hold the heat from the stove as much as possible. There is an old saying that "The best is the cheapest," and it will hold good in this case, and your committee desire to offer the following: That a first-class white pine tank, placed at an elevation of 25 ft. above rail on a steel substructure and stone foundation and connected with a 12-in. pipe to a 10-in. stand-pipe, is the most economical and modern structure of the kind at the present time.

The report also presented itemized figures of cost of three standard tanks. A 16 × 24-ft. white pine tank and tower on the Chicago & West Michigan R. R. cost $973.80, of which $228 were for stone foundation, $161.37 for labor of erecting, $25.50 for labor of painting and the remainder for material. A 20-ft. cypress standard Lehigh Valley R. R. tank cost $896.77, of which sum $280 were for masonry and $175 for labor. The Chicago, Rock Island & Pacific R. R. standard tank costs as follows:

16 × 24-ft. tank with 12 hoops, 3 lugs each	$275.00
1 indicator	5.00
1 set 7-in. fixtures	68.00
12 iron post caps	24.00
Rail joists, at $5 per ton	18.45
Substructure, frost proofing, etc.	198.36
Paint	14.51
Foundation stone	68.75
Labor in foundation	116.00
Labor, painting	24.24
Labor, erecting tank	164.72
Total	$973.03

The discussion which followed was quite extended, but few facts differing from those in the report were presented. Mr. W. A. McGonagle (Duluth & Iron Range) stated that in a climate which often presented a temperature of — 56° F. to — 60° F. he used a 16 × 24-ft. tank made of 3-in. cypress, with timber tower and masonry piers on an 18-in. concrete foundation. The tank was placed at the extreme edge of the right of way and a stand-pipe was used. The pipe from the pump to the tank was boxed in and carried on a trestle above ground. The pipe box was made of boards and tar paper with three dead air spaces, and through it passed a ¾-in. steam pipe from the boiler. With this construction no trouble was had from freezing. Mr. M. Riney (Chic. & N'wn) gave the costs of three 16 × 24-ft. white pine tanks recently built as: (1) labor $352, material $955, total $1,307; (2) labor $433, material $1,671, total $2,104; (3) labor $467, material $1,715; total $2,182. These figures included cost of everything.

The next report considered was that of the committee on "Best and Uniform System of Records for Bridge and Building Department." It was in abstract as follows and was not discussed:

> We have received from a number of roads copies of forms used by them, and find that with the exception of time books, there is a great diversity of forms and methods of reporting. In many cases the forms are for general use of the various departments of the system, and seem to be prepared to suit the general accounts, and also indicate that the statements required of expenditures on bridges and buildings differ in almost every instance. Therefore, on account of the various conditions under which bridge and building department work is performed on the different systems, and by reason of the fact that in many cases the forms are adapted to general use, and that any change might affect the general accounts, we have deemed it best to recommend only the following forms, and have arranged and classified all the other forms submitted so that they may be examined by the members and notes taken of such as are suited to their respective roads. The forms recommended are: Time Book to be 4½ ins. × 7 ins., and the number of leaves to be varied in accordance with the size of the crew. Covers to be oil boards with cloth back. This book is recommended because it shows the over-time. It is intended that it shall be in use one month only, and retained in the office of the person making the distribution of time. For reporting material used, Mechanics' Diary, U. P. system, the number of pages in the book to be determined by the road using it. Bridge and Building Record Account Book, the C., M. & St. P. Ry. system, which is to record in an ordinary journal-ruled book the charges to the work as they appear in the monthly distributions of labor and material, and when the structure is completed to analyze the cost. In our opinion the above forms are the best, and can be adopted by any of the roads submitting forms without any serious alteration in their methods of reporting.

No discussion followed the next report, which was that of the Committee on "The Mechanical Action and Resultant Effects of Motive Power at High Speed on Bridges." The committee announced its inability to present anything new on the subject, but briefly summarized some of the experiments made in the past and already familiar to the readers of Engineering News.

Mr. G. W. Hinman (L. & N.) presented an individual report upon the "Best and Most Economical Railway Track Pile Driver," the committee as a whole not reporting. Mr. Hinman described the pile driver used on the Louisville & Nashville R. R. The driver is of a pendulum form and capable of driving piles either plumb or at any batter. It has two centers so that piles can be driven close to either end of the car or 15 ft. from the forward end of the car. A double-action 7-in. cylinder Lidgerwood engine with two friction drums and two winch heads operated a 3,300-lb. hammer by the frictions. The hammer rope is a 2½-in. manila and is made fast to the hammer. On the driver is a water tank of 300 gallons capacity and a coal box of 25 bushels capacity. Accompanying the driver is a locomotive and tool car. One end of this car is boxed in for 24 ft., but the remaining 10 ft. is left open for a hand-car, pile rings, and coarse tools. The cost of running this driver per day is as follows:

Foreman and ten men	$22.00
Engineer, fireman and watchman	6.80
Conductor and flagman	7.00
Coal, oil and waste	2.50
Use of locomotive	12.00
Use of driver and tools	2.50
Total	$52.80

For long trestles of from 3,000 ft. to 4,000 ft. the gang is enlarged to a foreman and 14 men.

In the discussion which followed a number of members spoke in favor of the self-propelling pile driver made by the Bay City Industrial Iron Works, but Mr. N. W. Thompson (P., Ft. W. & Chic.) stated that it had proved unsatisfactory on his road. The general opinion was that manila or "stevedore" rope was better for hammer lines than iron or steel wire cables. This discussion was followed by several business committee reports which concluded the proceedings of the second day's session.

Thursday Morning Session.

The session of the association on Thursday morning was devoted to the election of officers, selection of next place of meeting, adoption of resolutions and the discharge of routine business. The following named officers were elected: President, James Stannard, Wabash R. R., Kansas City, Mo.; First Vice-President, W. G. Berg, Lehigh Valley R. R., Jersey City, N. J.; Second Vice-President, J. H. Cummin, Long Island R. R., Long Island City, N. Y.; Third Vice-President, A. H. Markley, Chicago & Eastern Illinois Ry., Danville, Ill.; Fourth Vice-President, R. M. Peck, Missouri Pacific Ry., Pacific, Mo.; Secretary, S. F. Patterson, Boston & Maine R. R., Concord, N. H.; Treasurer, N. W. Thompson, Pittsburg, Ft. Wayne & Chicago R. R., Ft. Wayne, Ind.; Executive Committee, W. N. Noon, Joseph M. Staten, W. O. Eggleston, M. Riney, C. P. Austin and G. J. Bishop.

Resolutions were adopted expressing the obligations of the convention, for favors shown by the Illinois Central and Santa Fe railways, the Pullman and Wagner companies, the mayor and the city of Chicago, the Western Railway Club, the Patterson-Sargent Co., the Sherwin-Williams Co., the technical press, and the local committee of arrangements. At noon the convention adjourned to meet in Denver, Colo., on the third Tuesday in October, 1897.

Excursions and Entertainments.

On Thursday afternoon a visit was made to the Burnside shops, Illinois Central R. R. (Eng. News, June 18, July 16 and 23, 1896), and to the town of Pullman. On Friday a number of the members made a trip along the Chicago Drainage Canal. A theater party and other entertainments were provided for the members by the Patterson-Sargent Co., of Chicago, and the Sherwin-Williams Co., of Cleveland, O.

ELECTRIC SWITCHING OF CARS on the Brooklyn Bridge cable railway will soon be in operation. The 20 motor cars built by the Pullman Palace Car Co., are now being delivered, and are being fitted with the General Electric Co.'s motors and equipment. The cars and the system of operation were fully described in our issue of Feb. 26, 1896, but since then the plans have been somewhat changed. The current will not be taken from an overhead wire, but from a third rail, for which purpose each truck will have on each side a collecting shoe, mounted between the axle boxes. The cars are of the usual type employed on the bridge, each having two four-wheel trucks, and each motor car will have four 50-HP. motors. There are two circuit breakers, a magnetic fuse box, 12 resistances and a magnetic blow-out. The motor car of each train will do the switching at each terminal, and will be able to propel the train load of 120 tons over the bridge (on emergency) at the same speed as the cable, 11.3 miles per hour, and to ascend the grades of 3.78%, which are 1,000 ft. long. The trucks for the new cars were made by the McGuire Mfg. Co.

A LOCOMOTIVE FOR THE SOUDAN RAILWAY, in Egypt, has been built by Manning, Wardle & Co., of Leeds, to the orders of John Birch & Co., of London. It is a tank engine, with outside cylinders, Walschaert valve gear, six coupled wheels, and leading and trailing pony trucks. The railway is a military expedition line of rough construction, with sharp curves and grades up to 2%. The leading dimensions of the locomotive are as follows:

Gage	3 ft. 6 ins.
Fuel	Coke.
Driving wheels	3 ft.
Truck wheels	2 ft.
Driving wheel base	6 ft. 6 ins.
Total wheel base	18 ft. 8 ins.
Cylinders	14×18 ins.
Tubes, diameter outside	1⅞ ins.
Boiler pressure	140 lbs.
Grate area	9.25 sq. ft.
Heating surface, tubes	545.00 sq. ft.
Heating surface, fire-box	62.00 sq. ft.
Heating surface, total	607.00 sq. ft.
Capacity of tanks	1,080 gallons

THE NEW FREIGHT TERMINALS of the Illinois Central R. R., at New Orleans, La., were formally opened Oct. 28, with some ceremony. In the evening Mr. Stuyvesant Fish, president of the railway, gave a dinner to the mechants of the city.

AN UNDERGROUND RAILWAY IN PARIS, about 11,054 ft. long, is to be built to transfer the terminal station of the Compagnie d'Orleans from the Place Valhubert, some distance up the Seine, to the Quai d'Orsay, opposite the gardens of the Tuileries and in the heart of Paris. The new line will follow the left bank of the Seine and will be, for the greater part, in a double track masonry tunnel, with the floor just above the level of the water in the river. About 2,027 ft. near the present station will be a sunken track, open above. The total estimated cost is about $4,600,000.

AN AMERICAN-CHINESE SYNDICATE, says a news item from Pekin, has promised to advance 30,000,000 taels, or less than $15,000,000, for the construction of the Han-Kow & Peking railway, a line 700 miles long, and crossing 27 rivers, including the Hoang-Ho. Rumors of similar Chinese railway construction with American money are, unfortunately, abundant; and whether this will result in anything more substantial than a news item remains to be seen.

A DEVICE FOR RAISING SWING BRIDGES for the purpose of renewing the roller system and making other turntable repairs has recently been tested with very successful results at Chicago, Ill. This device is the invention of Mr. J. E. Roemheld, Engineer of Bridge and Viaduct Repairs, Chicago, Ill., and it was first used in raising the Clark St. bridge, which is a double roadway, three-truss structure 220 ft. long, 58 ft. wide, and weighs 800 tons. Work was begun at 10 a. m. and finished at 5:30 p. m., during which time the set of 80 rollers was replaced, engine and boilers overhauled and sundry minor repairs made. No falseworks or jack screws were used and the labor force was 20 men. The raising device consisted of a series of interlocking cast-steel wedges so arranged that the bridge is turned up onto them and thus raised. In a future issue a full illustration and description of these wedges will be given, but at present it can only be stated that they worked with absolute success.

THE MOST SERIOUS RAILWAY ACCIDENT of the week was a collision between a fast freight train and three loaded oil tank cars standing on the track at Wapakoneta, O., on the Cincinnati, Hamilton & Dayton R. R. The engineman, fireman and one brakeman were killed, and the wreck caught fire; 12 freight cars and the pumping station of the Manhattan Oil Co. were destroyed by fire. ——An express train on the Eastern Division of the Boston & Maine R. R. ran into the open draw of the bridge over the Saugus River, near West Lynn, Mass., Oct. 30, The train was the "Flying Fisherman," from Boston to Rockport, and the drawbridge had been almost closed when the train reached it. Gates were closed across the track 500 ft. from the bridge, and red lights were displayed, and this was admitted by the engineman, but he claimed that the brakes would not hold the train. The engine went through into the river, with its rear end resting upon the abutment. Nobody was hurt.

A GAS EXPLOSION IN A MINE occurred at Wilkes Barre, Pa., Oct. 29. The explosion occurred in No. 3 shaft of the Lehigh & Wilkes Barre Coal Co., killing four men, while two men of the rescue party were suffocated by the after damp.

DEFECTIVE BUILDING WORK IN NEW YORK has again been detected. A 7-story building for manufacturing purposes is being erected at 508 and 510 Broome St., and on Saturday it was noticed by an inspector of the Building Department that the walls were bulging. Mr. Constable, Superintendent of the Department, made a personal inspection, and sent for contractors to shore up the walls and secure them by wire cables. It is said that defective construction, undue haste in the erection of the three top stories, and the jarring from the engine used to hoist material, contributed to the failure of the work.—— Building inspectors have also found a dangerous building at 158 Leonard St., which was in use as an Italian school. The building had settled so that the walls were cracked and had bulged out, while the floors had sagged down considerably. Steps were at once taken to shore up the building.

CIVIL SERVICE EXAMINATIONS will be held by the New York City Civil Service Board as follows: Enginemen, Nov. 11; sanitary inspector for the Health Department, Nov. 12; instrument maker for the Fire Department, Nov. 16; bacteriologist, salary $1,200 per year, and assistant bacteriologist for the Health Department, $600, Nov. 24; second deputy superintendent of buildings ("competent architects or builders of at least 10 years' experience"), Nov. 30. Particulars may be obtained of Mr. Briscoe, Secretary of the Commission, Criminal Court Building.

EXTENSIVE IMPROVEMENTS TO THE WATER SUPPLY of Baltimore are proposed, in accordance with plans outlined in a report by Mr. Samuel M. Gray, M. Am. Soc. C. E., of Providence. The estimated cost of the work is $1,985,700, divided as follows: 75,000,000-gallon reservoir and land for same, $450,000; two 17,500,000-gallon pumps in place, $130,000; one 10,000,000-gallon pump, $35,000; five 150-HP. boilers in place, $15,000; pumping station, $90,000; pipe system, $1,059,700; screens and accessories, $12,800; high service improvements, $193,200. Bids for 26,000 tons of cast-iron pipe will be received until Nov. 16, as stated in our advertising columns. It is reported that the other contracts will not be let until next spring. Mr. W. L. Kenly is Chief Engineer of the Water Department.

THE NAVAL BUREAU OF ORDNANCE, says Capt. Sampson, Chief of the Bureau, in his annual report, has built 450 guns of large caliber, has 89 partly built and has only condemned two out of this number in official tests. All of the 6-in. guns on hand are to be converted into rapid-fire guns, and the appropriation of $250,000 for reserve guns is being utilized in constructing two 8-in., two 12-in. and two 13-in. guns. Smokeless powder is on hand for all guns up to 6-in. caliber. During the year 2,262 tons of armor have been delivered, 684 tons of this being reforged plate. The two armor-making companies now claim an annual capacity of 8,400 tons. As auxiliary cruisers the department has inspected and accepted 19 American steamers on the Atlantic coast and 9 on the Pacific coast. These ships will require 46 6-in., 27 5-in., 104 4-in., 54 6-pdr. 8 1-pdr. and 112 machine guns. The estimates for the next year aggregate $9,164,620, the largest item being $7,720,796 for the armament of vessels authorized.

THE UNITED STATES NAVY, says Chief Constructor Hichborn in his annual report, now contains 110 vesesls of all classes; of these 30 are armored, including 8 battleships, two cruisers, one ram, 6 double-turreted monitors and 13 single-turreted monitors. Three other battleships are under construction. There are now in commission 25 new steel cruisers, with 16 iron and wooden cruisers.

FOREST DESTRUCTION AND FRESHETS in mountain streams are discussed in the annual report of Mr. T. Jefferson Coolidge, Treasurer of the Amoskeag Cotton Mfg. Co., of Manchester, N. H. For some years past there have been heavy spring freshets in the Merrimac River (that of 1896 compelling a general shutting down of the mills at Manchester), while in summer the water is lower than in former years. This alternation of very high and very low water is attributed by Mr. Coolidge to the cutting down of forests around the headwaters of the Merrimac, the Pemigewasset and other affluents. The woods held back the water, but now that they have been largely destroyed the rain, running rapidly over the surface of the ground, which is baked by the sun or frozen hard by the winter cold, pours all at once into the streams, turns them into roaring torrents, and finds its way all at once into the Merrimac, sweeping everything before it. In a few days the river sinks rapidly and becomes in time of drouth an insignificant stream.

THE PENNSYLVANIA FORESTRY COMMISSION, Wm. F. Shunk, Engineer, reports that there are in that state 13,973,737 acres of cleared land, and 9,099,817 acres of woodland. Both Mr. Shunk and Prof. Rothrock, the Forestry Commissioner, recommended the purchase of forest reserves by the state, both to better protect standing timber from fire and to perpetuate our forests. They say that unless something of this kind is done at once the state will be denuded of valuable timber within the next 15 years. During recent years one firm of lumbermen has lost 150,000,000 ft. B. M. of timber by forest-fires. In the past season one tract of 125,000 acres was thus devastated.

DURING THE CONSTRUCTION OF THE MELAN arch bridge, at Topeka, Kansas, the remains of another bridge were encountered in the foundation, a bridge forgotten by nearly everyone now living in Topeka, though it was only built late in "the fifties." Topeka was then a village, and a bridge was built across the river, with pile-piers and a swing-span for the accommodation of passing steamboats. The bridge fell almost immediately after its completion, and the wreck was soon buried in the sand by a shift in the channel and forgotten. The oak piles in the foundation of the old pivot-pier, which were encountered in founding the Melan arch, were in an excellent state of preservation, and they are being withdrawn for use under the new piers.

PANAMA CANAL WORK, says a Panama news item, is being "pushed" on the Culebra Section with a force of 150 negroes. The American system of handling earth by towers, endless chain of buckets, etc., copied from some of those used on the Chicago drainage canal, has been introduced on the Empire Section, and is said to work well. M. Belin, the Director-General for the new canal company, has arrived at his post. He is not an engineer, but a lawyer, formerly connected with the administration of the old canal company.

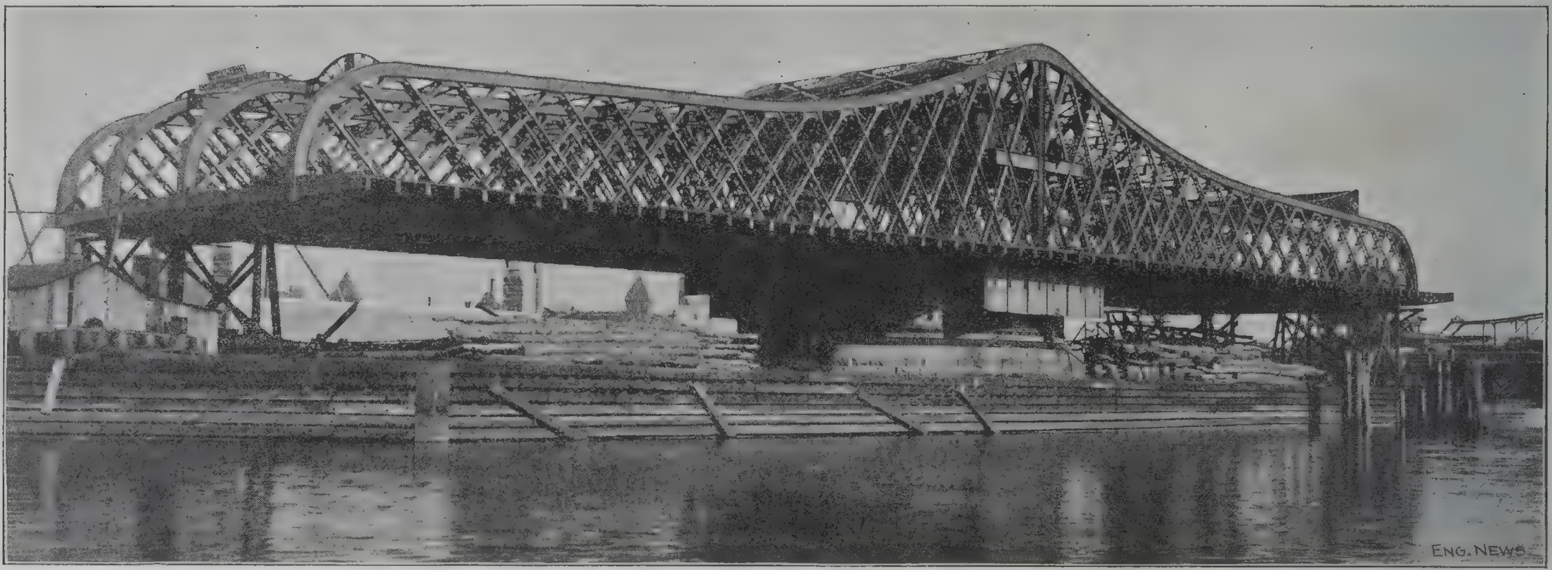
WOODEN PAVEMENTS seem to have little connection with politics, other than in the contract stage of their existence; but the authorities of Chicago, through the Chief of Police, have forbidden the use of the wooden blocks for making election bonfires. Boys have been caught tearing up the blocks on Jackson Boulevard and storing them away for this purpose.

BRICK PAVING FOR COUNTRY ROADS is being tried near Monmouth, Ill. About 3,000 ft. of brick pavement have been laid in Monmouth township (Warren county), there being a single course of brick laid on 6 ins. of sand, while a strip of 30 ins. of broken stone paving is laid on each side of the brick. The cost is said to be less than $5,000 per mile.

THE THIRD AVE. DRAWBRIDGE OVER THE HARLEM RIVER; NEW YORK CITY.

We illustrate herewith the drawspan for the new Third Ave. bridge over the Harlem River, New York city, which is now completed, and will be opened to traffic as soon as the approach spans are finished. This is one of the largest and heaviest drawbridges ever built, and it is notable not only for its size, but for the attempt which has been made to improve its appearance. While the truss is of the general form which has become a standard for swing spans of this class in America, curved outlines have been adopted for the top chord in place of the angular outline which such a truss usually presents, and the top chord has been emphasized in the construction.

There may be some things in the field of engineering construction which are more awkwardly ugly than the ordinary swing span truss as usually constructed, but we do not now recall what they are. The attempt to remedy this by the introduction of curved outlines which has been made in the present case is a most interesting experiment, and opinions will doubtless differ as to its success. We are inclined to believe that a more radical departure must be made from conventional forms if the swing span is to be made a thing of beauty.



DRAWBRIDGE OVER THE HARLEM RIVER AT THIRD AVE., NEW YORK CITY.
Thomas C. Clarke, M. Am. Soc. C. E., Engineer. Phœnix Bridge Co., Builders.

As an engineering structure the bridge is especially notable for its use of multiple-intersection lattice trusses in a structure of such magnitude. These, with the curved top chord, have made necessary great care and accuracy in the shop and field work.

The span is 300 ft. long and 87 ft. 6 ins. wide over all. The Act of Congress authorizing the rebuilding of the Third Ave. bridge, requires a clear headway of 24 ft. above high water. The limited space available for approaches on the south side of the river made it necessary to design the draw with a very thin floor, not over 20 ins. deep, in order to keep the approach grades down to 3%. This made it necessary to place the trusses near together, and the bridge is therefore built with four trusses, dividing the floor into two carriage roadways and a roadway for a double track electric railway, the latter being between the middle trusses. The three roadways are each 20 ft. wide, and two sidewalks 9 ft. wide are carried on cantilever brackets outside the trusses. The depth of the trusses is about 38 ft. at the center and 18 ft. at the ends. The floor system is of buckle plates, covered with concrete and an asphalt pavement for roadways and sidewalks. The weight of the draw is 2,500 tons, and this is carried on a turntable of 60 ft. diameter, which is said to be the largest ever built, that of the 400-ft. four-track drawbridge carrying the New York Central R. R. across the Harlem River being 54 ft. diameter. There are 80 wheels, 24 ins. diameter and 12 ins. wide, running on a track 60 ft. in diameter. The bridge can be turned easily by hand power.

The traffic over the bridge and on the river is very considerable, being approximately equal to that of the Chicago River and the main bridges across it, and this traffic is rapidly increasing. The traffic over the temporary drawbridge at Third Ave., during the 24 hours between 12 p. m., July 9, and 12 p. m., July 10, included 4,996 vehicles, and the draw was opened 60 times during that period, the aggregate time of opening being five hours. The traffic on the Harlem River amounted to 5,910,376 tons in 1893, while foreign shipping from the port of New York amounted to 7,000,000 tons in the same year.

In view of this very heavy traffic it was therefore important to devise such machinery for operating as would swing the bridge quickly and would reduce to the lowest degree the liability to failure. The problem to be considered was the best method of swinging a bridge span weighing 2,500 tons through a quarter of a circle in two minutes, several times a day. This work can be done by a 50-HP. engine but in order to prevent closing the bridge for repairs or minor accidents, a duplicate plant is fitted, consisting of two 60-HP. boilers, and two double cylinder (7 × 10 ins.), inclined, oscillating engines, either of which can operate the bridge at half speed. The boilers also supply steam for the end locking gear, and for a 35-HP. dynamo for lighting purposes. The machinery is placed in a powerhouse between the trusses. In preparing to open the bridge, the engineman first signals the gatemen, who close the gates on the outer end of the fixed approach spans. He then simultaneously withdraws the central locking bolts, runs up the eight supporting nuts and eight hydraulic rams under the ends of the four trusses, and also raises the ten aprons (four for sidewalks, four for roadways, and two for electric railway) which cover the space between the draw and the fixed spans, while at the same time the rail connections of the electric railway tracks are also raised. These operations are performed simultaneously in about 10 to 12 seconds. The time occupied in swinging the span is such that the whole time occupied will not exceed two minutes for a full opening, and two minutes more for closing and locking the bridge.

There are two 117-ft. plate girder deck approach spans, one at each end of the draw, and these have a 50-ft. roadway paved with granite, and two 12-ft. sidewalks paved with limestone flags. Beyond these are masonry approach viaducts, that on the north side being in line with the bridge, while at the south end the approaches curve away in either direction, almost at right angles to the bridge. The north approach is 60 ft. wide, and the two south approaches are 35 ft. wide. These approaches have no sidewalks, the sidewalks of the bridge proper being reached by two stairways 12 ft. wide. A movement is on foot to have another approach from the Southern Boulevard, on the north side, and to extend one of the curved approaches on the south side to the west of Third Ave. All the stone work is rock-faced, except the cut granite balustrades, railings and curbs.

The detail bids for this entire structure were given in full in our issue of Sept. 7, 1893. The total cost of the bridge, including land, will be from $2,000,000 to $2,500,000.

The bridge was designed by Mr. Thomas C. Clarke, M. Am. Soc. C. E., and the machinery was also built under his specifications and direction. Mr. Geo. W. Birdsall is engineer in chief of the whole work by virtue of his position as Chief Engineer of the Department of Public Works. The general contractor was Mr. Isaac A. Hopper, of New York. The drawspan was built by the Phoenix Bridge Co., of Phoenixville, Pa., of which Mr. John Sterling Deams, M. Am. Soc. C. E., is Chief Engineer. The machinery was built by Joseph Edwards & Co., of New York city.

NOTES OF A TRANSCONTINENTAL TRIP.

IV.

The Great Salt Lake.

On July 12 I took a trip to this remarkable lake, which is about 15 miles from Salt Lake City, and has two pleasure and outing resorts reached by rail. Garfield Beach is reached by a branch of the Union Pacific Ry., and Saltair Beach (which was the place visited) is reached by the Saltair Ry. (a branch of the Rio Grande Western Ry.). This latter line has engines built by the Rhode Island Locomotive Works, of Providence, R. I., and they are painted in an unusually gaudy style, with brilliant red wheels and a liberal allowance of gold leaf and varnish. The first car of the train is a closed combination baggage and smoking car, the other cars are open-sided excursion cars with 20 transverse seats, resembling in style the cars of the Coney Island lines, so familiar to New York people. The train lands its passengers at the entrance of the great pavilion shown in Engineering News, Nov. 9, 1893, from each side of which extends a curved trestle with rows of dressing rooms for bathers. The water of the lake is remarkably clear, and the bottom is of fine sand as soft as a velvet carpet. It was also pleasantly warm and afforded a most enjoyable bath. The water has a specific gravity of 1.107 and contains 17 to 27% of saline contents (varying at different parts of the lake.) The bulk of the saline contents is common salt. The Dead Sea has a specific gravity of 1.116 and contains about 24% of saline contents, while ordinary sea-water has a specific gravity of 1.026, and contains 3 to 5% of saline contents. The lake is about 80 miles long and 30 to 50 miles wide, with an average depth of 20 ft. and a maximum depth of about 80 ft. It receives the Jordan, Weber and Bear Rivers, but has no outlet. There are two large islands, 12 and 16 miles long, with hills as high as 3,000 ft., and having good fresh water springs; besides these there are a number of smaller islands. On the south side are the mountains, while dry desert and salt marshes form the south and west sides, and irrigable lands are on the east side. The old water line is plainly visible on the rocky sides of the mountains.

Salt Lake City to San Francisco (So. Pacific Ry.).

I left Salt Lake City on the Pacific mail train of the Rio Grande Western Ry., July 13. The line follows mainly the course of the lake shore to Ogden, 37 miles, where the Rio Grande Western Ry. terminates by a junction with the Union Pacific Ry. There is a handsome station here, built beside the tracks and having no trainshed or platform sheds. The through cars for this latter line are here attached to the Overland Limited Express which runs over the Chicago & Northwestern Ry. and Union Pacific Ry. to Ogden, and thence over the old Central Pacific Ry. (now the Central Pacific Division of the Southern Pacific Ry.) to San Francisco. This train, on July 13, was made up of seven cars; a fast freight car, baggage and mail car, day car, tourist sleeping car, dining car and two sleeping cars. It was hauled by a ten-wheel engine, built by the Cooke Locomotive Works, of Paterson, N. J., one peculiar detail of which was a step attached to the crosshead, evidently to give the cleaners access to the running board without climbing up on the front end. On the Sacramento Division, running between Sacramento and Truckee, are some immense twelve-wheel engines with cylinders 22 × 26 ins., and weighing 173,000 lbs., with 145,000 lbs. on the eight driving wheels. These engines are reported by Mr. H. J. Small, Superintendent of Motive Power, to be giving remarkably good service on the heavy mountain grades over the Sierras.

Near the track, at Sacramento, were seen the works of Schaw, Ingram, Batcher & Co., manufacturers of riveted sheet, steel and iron pipe for mining, irrigation and power purposes.

Southern Pacific Ry. (Central Pacific Division).

The Central Pacific Ry. was one of the two great lines whose construction was assisted by the United States government in order to secure a transcontinental railway line. The total amount of subsidy issued to the Central Pacific Ry. was $27,855,680, and about 12,000,000 acres of land. The line was to extend from San Jose to Ogden. Work was commenced at Sacramento in February, 1863, and the connection with the Union Pacific Ry. was made on May 10, 1869. The communication with San Francisco was at first by steamer, until the Western Pacific Ry. was opened from Sacramento, and this was later superseded by the California Pacific Ry., which has a route 60 miles shorter, but includes a ferry crossing of the Carquinez Strait. The Central Pacific Ry. is now leased to the Southern Pacific Ry. for 99 years from April, 1885.

On leaving Ogden the railway at once begins to ascend from the level of the Jordan Valley, the grades being pretty heavy in places and combined with sharp curves. The valley here is composed of salt marshes and desert land, and high upon the hills is plainly visible the water line of the former level of the lake. For several hours the dark blue lake and its mountain islands are present to the view; in fact as far as Monument, 77 miles from Ogden. For many miles one sees on the south side of the line evidences of a partly graded roadbed, with cuts and fills, the grade being usually below that of the existing line, but running out into the latter at Promontory, Corinne, etc. This is part of the line built by the Union Pacific Ry. when the transcontinental line was under construction, and the point of junction of the Union Pacific Ry. (from the Missouri River) and the Central Pacific Ry. (from the Pacific Coast) had not been decided upon. Both companies built as fast as possible in order to gain the subsidies for length of line, and as many men were put on as could work without getting in each other's way. The graded lines overlapped for nearly 200 miles, but the actual meeting of the tracks was made at Promontory, on May 10, 1869. Ogden was afterwards settled upon as the junction point. At Kelton, 92 miles, is the water supply station for the westbound trains, which here strike across the northern edge of the Great American Desert for a distance of nearly 100 miles, the line being on an ascending grade and reaching an elevation of 5,975 ft. at Toano, on the western border of the desert. The general appearance of the desert is similar to that of the Utah Desert, already described, being a sand with sufficient loam to form a thin, flat scale like the cracked mud bottom of a dry pond, and to form a thin, slimy mud when wet by the occasional furious rainstorms, which are preceded by wind and sand storms. The train passed through one of these storms, the blinding sand being followed by a drenching rain, which effected a welcome cooling of the atmosphere.

From the desert the line ascends the Cedar Pass, climbing the Divide between the desert and the Humboldt Valley. Here the snow sheds and snow fences begin to appear, and the summit is reached at Moors, 6,167 ft. above sea level. Beyond this there is an almost continuing descent to Browns, 610 miles, the elevation of which is 3,929 ft. About 140 miles of this distance is across the desolate Nevada Desert, which, however, this train crosses at night. The speed is considerable at times, 40 to 50 miles per hour, but though the track is fairly easy riding for the Pullman cars, it was the least easy of any thus far encountered. Reno, 4,497 ft. elevation, is the junction for Carson City and Virginia City, in the great silver and gold mining district of which the Comstock mines are the most celebrated. Here begins the ascent of the Sierra Nevada, amid the scenery of pine-clad slopes and peaks which are characteristic of this region and which are a great relief after the sand and dust and glare of the Utah, American and Nevada deserts. For many miles the line follows the rushing and tumbling clear Truckee River, and, rising from it are seen the long, steep chutes of plank, down which the logs are sent from the hill tops to the river. Unfortunately, the snowsheds begin at Truckee and continue almost without a break for 40 miles, so that, as there is no outside line for summer traffic (as on the Canadian Pacific Ry.) much of the view is lost. Glimpses of snow patches are seen through the loopholes, however The station at Summit (elevation, 7,017 ft.) is in the snow shed, and at intervals the sheds are wide enough for a side track for passing trains, or for the water train for protection from fire. In view of the stifling fumes and gases from the engines in this 40 miles of tunnel, which are very trying to the lungs, it would seem as though in summer some of the roof boards should be removed for ventilation, which is not sufficiently provided for by the gaps between the boards forming the walls. This removal of boards is indeed carried out to some extent, but not enough to ameliorate the certain inconvenience and possible dangers arising from inhaling these fumes. From Summit the train goes coasting down the Pacific slope of the range at high speed, amid magnificent scenery, the descent being almost continuous from Summit (7,017 ft.) to Sacramento (30 ft. above sea level). The distance is 105 miles, and is made in five hours. A few miles east of Sacramento is the junction with the Southern Pacific Ry.'s main transcontinental line (through southern California and Texas), and its line north to Portland, Ore.

PIER AND TURNTABLE FOR THIRD AVE. DRAWBRIDGE.

The track is laid mainly with 75-lb. rails, having square suspended joints with 24-in. splice bars and pin bolts. Servis tie-plates are very extensively used, many of these being four-flanged plates with four spike holes for double spiking on curves. Redwood ties are used, and some old ones in the Sacramento station appeared to be in very good condition. Across the desert the telegraph poles are square sawed posts, with the insulators attached to the underside of the crossarm. The train of eight cars was hauled by two ten-wheel engines, and it was noted that some of the road engines have a hose reel and fire hose on the top of the rear end of the tender tank, while some of the switch engines have also a fire pump mounted on the boiler. The station at Sacramento is worthy of comment in that it is one of the few large stations provided with a trainshed.

The train now passes through the fertile Sacramento valley, with its extensive fields of grain dotted with numerous groups of fine oak trees. West of the city the line passes over flat swampy grass lands (the "tules"), over which thousands of birds are flying, and then again across more rich agricultural country with quantities of fine trees, the bright fresh green of which is most refreshing to the eyes after days of rocky scenery, desolate hills, barren desert, or even the dark pines of the Sierra Nevada.

At Benicia the railway is cut by the Carquinez Strait, an arm of San Francisco Bay, across which the whole train is ferried on the transfer steamer "Solano." At Port Costa the train again runs ashore, and continues its trip to Oakland, running out upon a pile and rock-filled pier nearly two miles long, in the bay. At the end of the pier is a trainshed and ferry house building 1,050 ft. long over all. The trainshed has a central portion 120 ft. wide and 60 ft. high, and two side portions 60 ft. wide and 40 ft. high, these latter portions being used for the suburban traffic. At the end of the central part of the trainshed is the headhouse building, containing a waiting room 120 × 120 ft., restaurant, offices, etc., and from the waiting room there is access to the upper deck of the large sidewheel ferry steamers running between Oakland and San Francisco.

Railway Ferry Steamer "Solano;" Southern Pacific Ry.

This is the largest car ferry steamer ever built. It plies between Benicia and Port Costa, across the Carquinez Strait, 12 miles from San Francisco, the total length of trip being about two miles and the time less than ten minutes from stop to start of train. The vessel was designed in 1884 by Mr. Arthur Brown, while Superintendent of Bridges and Buildings of the Central Pacific Ry., and it was required that it should have capacity for the longest freight trains on the line. Some idea of its size may be gathered when it is stated that the deck is 424 ft. long and 116 ft. wide, with four tracks having a capacity for 48 freight cars or 24 passenger cars, with locomotives. The hull is of wood, stiffened by four longitudinal Pratt trusses under the deck. It is divided into 12 compartments, and contains the quarters for the officers and crew. There are two vertical engines with walking beams, both placed on the center line of the hull, and each driving one of the side wheels, the shafts being 16 ft. apart c. to c. The engines occupy a superstructure in the middle of the vessel, while the four batteries of boilers (fore and aft of each paddlebox) are in the superstructures erected on the guards, or the overhanging portions of the decks. There are four smokestacks. The steering is effected by four balanced rudders, 11½ × 5½ ft. each, at each end of the boat, the set of rudders at the bow (in either direction) being fixed. The four rudders are coupled together and operated by hydraulic machinery, which, as well as the hand steering gear, is operated from either of the two large pilot houses on the end bridges of the vessel. The engines were built by Harlan & Hollingsworth, of Wilmington, Del. By means of the large rudders and the independent engine to each wheel this great craft can be easily handled in the current, which runs at the rate of eight miles per hour. At either end of the trip the boat runs into a slip formed by guard piles, while an apron 100 ft. long, having five combination bowstring trusses, is adjusted by hydraulic power to fit the level of the deck, being latched to the boat. This apron has four tracks. A full description of this interesting vessel with illustrations may be found in a paper on "The Railway Ferry Steamer 'Solano,'" by Mr. Robert L. Harris, M. Am. Soc. C. E., in the "Transactions of the American Society of Civil Engineers." The leading dimensions of the vessel are as follows:

Length on deck	424 ft. 0 ins.
Length between perpendiculars	406 " 0 "
Beam of hull	64 " 0 "
Width of deck, over guards	116 " 0 "
Draft, light	5 " 0 "
Draft, loaded	6 " 6 "
Height at centre	18 " 5 "
Height at ends	15 " 10 "
Camber of deck	2 " 4 "
Tonnage, registered	3,541 tons
Engines (2)	2,000 HP.
Cylinders (1 to each engine)	5 × 11 ft.
Boilers, number	8
" length	28 ft. 0 ins.
" diameter	7 " 0 "
Tubes, number	143
" diameter	4 ins.
" length	16 ft. 0 ins.
Heating surface, total	19,640 sq. ft.
Grate area, total	288 "
Wheels, diameter	30 ft. 0 ins.
" number of floats	24
" size of floats	17 × 2½ ft.
Apron at slip, size	100 × 44½ ft.
" weight	150 tons

STREET RAILWAY TRUCKS.*

By John N. Akarman.

The term truck, in this case, means the separate framework for holding the running gear of an electric car; namely, the wheels, springs, brakes, motors, etc. When motors were first placed upon street cars, it was believed that there was no necessity for special construction, or any marked departure from the prevailing horse-car practice. The idea of a separate truck was first conceived about 1885, but it was not until the latter part of 1887 that, in its concrete form, it was put into operation.

The first truck consisted of a continuous upper chord made of bar iron in the form of a rectangle. Its purpose was to support the car body, the sills of which rested on its frame. The sides of this upper chord were re-enforced by heavy oak sub-sills to which the chord and the pedestals were both firmly bolted. This form of frame kept the body square and took many of the strains on itself; but it has been abandoned, and in abandoning it and using separate bars, I think we have been drifting away from the best practice, for it had a very important advantage in preserving the squareness of the body and truck. In addition to this upper chord, there was a bar extending around the truck to which the bottom of the boxes were fastened.

Springs over the axle boxes were unsatisfactory, from their stiffness in the limited space available, but by widening the box at the bottom, or adding ears so as to form spring seats, it was found possible to give each box two springs, one on each side, and of ample diameter and length so that they would carry the load with ease and have sufficient motion. Thus placed, they had the advantage of carrying the box perfectly steady, preventing entirely the rocking and unsteady motion. It was soon found that brakes upon electric cars were a very much more important feature than they had been upon horse cars. The brakes were first suspended from the sills of the car, and the sinking of the car body under a load left the shoe so far from the wheels that in applying the brakes, the slack of the chains was increased and could not be taken up without considerable delay. Another difficulty was the longitudinal rocking or pitching of the car body, which is not only excessively unpleasant to passengers, but very destructive to the trucks, motors and track. The lengthening of the wheelbase as a remedy for this did not prove to be of much advantage. The first success as a remedy appears to have been made by extending the sides of the truck, and mounting elliptic or semi-elliptic springs on the ends of the extension pieces. This latter method with the semi-elliptic spring has been the most successful preventative tried.

The composite frame demonstrated its imperfections with the locomotive years ago, and has been found even less successful as a form of construction for a motor truck. This is due in a measure to the fact that on account of cost, first class workmanship is out of the question in building a low-priced truck. The truck frame consisting of a solid forged bar, of course, gives greater strength to resist strains thrown upon it from all directions than any form of a built up truss. I believe the ideal four-wheel truck for electric cars at the present time is the one having the fewest number of parts in its construction, in which the side pieces of the main frame are single forged bars connected across the ends by bars either bolted or welded on so as to make the frame one continuous piece. This frame is carried by springs from the journal boxes, and itself carries an upper chord, likewise, a continuous rectangular piece which has suitable seats for the springs. This upper chord is recessed to take the bolts and spring seats, leaving its upper surface flush. The ends are carried by the half elliptic springs, while the spirals are placed at the journal boxes. The brake should be hung by links. Diagonal bracing is out of the question in the construction of a truck on account of the motors, but the diagonal strength is usually increased by the introduction of transoms. Such a frame carries its machinery with a certainty of its always being in alinement with the driving axle, and as it is spring carried, it is as light on the rails as any form of single truck, while the longitudinal oscillation is prevented by the peculiar effect of the half elliptic springs which do not respond readily to rhythmic motion.

At its best, however, the four-wheel truck is an uncomfortable carriage and a track destroyer, and should only be used where cars are run at comparatively slow speed, and with moderate length of car bodies. Where it is desirable to run at higher rate of speed in suburban service, the damage to the track becomes so great that it should preclude its use. The only alternative is to use a double truck car with swivel or pivoted trucks, and this is easy on curves to a degree that would hardly be credited by those who have only been familiar with four-wheeled cars. The greater number of wheels not only reduces the weight on each wheel, but correspondingly reduces the blow when the wheels strike a joint or a low place in the track. This is still further diminished by equalizing the springs, so that each wheel in rising or falling in passing over any imperfection in track elevates the load a distance but half as great as its own rise. Oscillation, whether longitudinal or transverse, can be completely done away with by the use of double trucks.

The conditions, however, are not altogether in favor of the pivotal truck. As for instance, if all the weight is used for adhesion it is twice as expensive in use as a four-wheel truck. If two motors are used, it only has 50% of the propelling power. In its ordinary form, it makes a wide body necessary and hence is out of place in narrow streets or places where traffic is very heavy. It also has the disadvantage of putting the body at a greater height than is necessary with four wheels.

The "maximum traction" truck may be defined as a pivotal truck in which the load is eccentrically placed in relation to the four wheels of each truck. Two of them receive only a sufficient amount of weight (20%) to keep them upon the track, while the others take the remainder of the load. It was found that it was not necessary to have the wheels of equal size. The large pair used as driving wheels, being very near the pivotal point, have a comparatively small amount of swing, and can be allowed to rise within the floor timbers, while the small wheels moving through a much greater arc easily clear the sills. By this form of construction, the body can not only be brought down, but the frame can be made as narrow as in the ordinary street car body. This form of truck enables the car to be utilized for both street and suburban service. It is also found in its latest form utilized under long open cars. It carries the motors in a satisfactory manner, guides readily and answers nearly all the requirements of the service.

As inter-urban service is almost equivalent to service on steam railways; for this service, pivotal trucks having regular swing beams, equalizers, elliptic springs, and all the parts of the steam railway truck are entirely satisfactory. They take curves easily at a high rate of speed. But for trucks which must run not only on trams, but on T rails, some form of the maximum traction truck will give, all things considered, the best service.

An important question to be considered in connection with the adoption of single and double trucks, is whether the punishment to the track by single trucks is not so great as to more than make up for the cost of putting in and running double trucks under all cars, whether short or long.

---

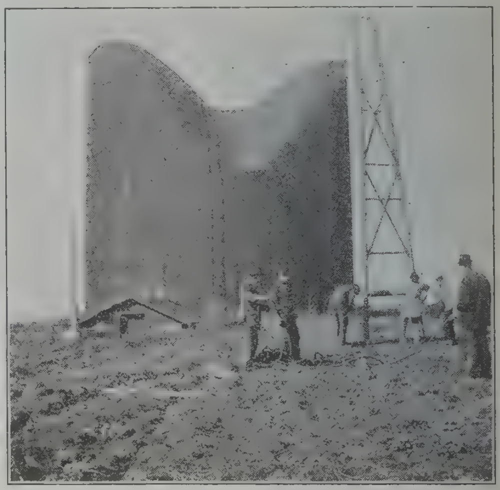
*Abstract of a paper presented at the Annual Convention of the American Street Railway Association at St. Louis.

A WIND-INDENTED STAND-PIPE AT CORTLAND, N. Y.

A partial wreck of a stand-pipe occurred at Cortland, N. Y., on Sept. 29, as shown by the accompanying reproduction of a photograph of the pipe after the accident. The accident seems to point to the necessity, at least in the case of so large a structure, of ample top stiffening.

The stand-pipe is on a hill about 150 ft. high. It is of ½-in. iron for the lower five sheets and ⅜-in. for the remaining distance to the top.

The accident occurred during the night of Sept. 29. A high wind wrecked many roofs in the village of Cortland and blew at an estimated velocity of 80 miles an hour for two hours. The recording gage showed 22 ft. of water in the pipe at the time of the accident, the water extending 2 ft. above the bottom of the bent portion.



View of Partially Wrecked Stand-Pipe; Cortland, N. Y.

Repairs were made by pulling the top back into place, attaching a 4 × 4-in. angle around the top, patching the hole at the break and guying the top by four 1¼-in. steel cables anchored to stone posts.

We are indebted to Mr. Wm. B. Landreth, M. Am. Soc. C. E., of Cortland, for the above information. The photograph from which the view was reproduced was kindly furnished Mr. Landreth by the Cortland Water-Works Co.

THE NEWTOWN CREEK BRIDGE COMPETITION.

(With inset.)

We present to our readers in this issue the designs submitted in the Newtown Creek bridge competition. The engineering problem presented for solution in this case is one of great interest, and one which is likely to come up very frequently for solution in the future. The various designs presented therefore are worth careful study.

Before describing the different designs, however, the principal facts in connection with this much discussed piece of engineering work may be set forth.

Newtown Creek is an arm of the East River which extends from a point about opposite 28th St., New York city, east and south a distance of nearly three miles. It is lined for a large part of its length with docks and wharves and manufacturing establishments, and in consequence a large traffic is continually passing in and out of it. The creek forms the boundary line between Brooklyn and Long Island City, and the Vernon Ave. crossing, only a quarter mile from the mouth of the creek, is the only means of direct communication between these two cities. The next crossing up the creek is on Greenpoint Ave., a mile further up the stream, and there is practically no means of reaching Long Island City

from Brooklyn by this route except by a long detour.

For many years the old wooden bridge, operated by hand power, which has done duty at the Vernon Ave. crossing, has been the subject of severe criticism; and about two years ago, we believe, the U. S. Engineer Officer in charge of the district declared it an obstruction to navigation, and intimated that no center-pier draw-span would be permitted to replace it; some type of movable bridge must be chosen which would give an unobstructed channel the full width of the creek when the bridge was opened.

It may be remarked in passing that the provision of a new bridge at this point has been greatly complicated and without doubt delayed by the fact that Newtown Creek forms the boundary line between Kings County and Queens County, and the joint action of the Boards of Supervisors of the two counties was necessary.

After much discussion of various plans, it was decided to build a bridge similar to the Halsted St. lift bridge in Chicago, designed by Mr. J. A. L. Waddell, M. Am. Soc. C. E., and illustrated in Engineering News of April 19, 1894. The clear span was to be about 140 ft., and the total height of lift about 150 ft.

Bids for constructing the bridge were advertised for, and on July 29 seven proposals were opened. The contract was then awarded to the lowest bidder, the King Bridge Co., of Cleveland, O., at its bid of $418,000.

Subsequently the award of the contract was vetoed by the Supervisor-at-Large, on the ground that the contract price was excessive, being $100,000 more than the estimate made by the county engineer of Queens Co., Mr. John J. McLaughlin, M. Am. Soc. C. E.. Shortly after this, legislation took effect which abolished the organization of Kings county, as it had become coterminous with the city of Brooklyn. The Kings County Board of Supervisors thus ceased to exist and its powers were transferred to the Board of Aldermen of the city of Brooklyn. Joint action of this body and of the Queens County Board of Supervisors thus became necessary to any progress in the matter of the Newtown Creek bridge.

After several months' delay a new scheme was agreed upon, and in July of the present year engineers were invited to submit designs for a bridge on the Vernon Ave. site. A peculiar feature of this competition was that no prizes or compensation of any sort was offered.

Each engineer submitting plans was required to state their price, and was warned that no compensation would be given to any except the one whose designs might be approved and adopted, and he must agree in advance that the entire charge for all his work should not exceed the price submitted with his design. Further, the right to reject any and all designs was reserved.*

On July 23, the designs received by the committee were examined. It was found that eight competitors had submitted plans for a bridge; and one engineering firm which had examined the location and concluded that a tunnel was a preferable solution of the problem submitted a brief advocating that construction.

The designs submitted, with two exceptions, are shown upon our inset sheet. Following the date set for the receipt of designs, plans were also submitted by Mr. Albert H. Scherzer, of Chicago, for a structure similar to the rolling lift-bridge; designed and patented by the late Wm. Scherzer, and in use at Chicago by the Metropolitan Elevated R. R. at its crossing of the Chicago River, and by the City at its Van Buren St. crossing. As this type of bridge was illustrated in our issue of Feb. 21, 1895, and as the design was not presented during the time fixed by the committee, we do not include it on our inset sheet.

After the receipt of the designs, the committee visited Chicago and examined the various types of bridges in use there. As a final result of its investigations it first adopted a resolution approving the bascule type of structure as the most suitable for the conditions existing at the Newtown Creek crossing, and later adopted the plans submitted by Mr. Thos. E. Brown, Jr., M. Am. Soc. C. E., 38 Park Row, New York city.

Turning now to the drawings upon our inset sheet, it should be explained that we have redrawn all the designs to uniform scale and in uniform style from drawings and blue prints kindly furnished by the several competitors. Necessarily, most of our drawings show much less of the details of construction than was shown in some cases on the designs submitted to the committee; but we have endeavored in every case to show enough detail to make clear the important features of the design.

Fig. 1 shows the design submitted by Mr. Brown. It is a hinged-lift structure in two halves, supported by towers on each shore and operated by hydraulic power. More in detail the design is described by Mr. Brown, as follows:

"The bridge consists of two hinged spans 80 ft. 4 ins. long from center of hinge to center of river, or a total of 176 ft. 8 ins. between hinges, and two towers about 74 ft. high, surmounted by houses for the operators.

The outer ends of each span will rest on steel trestle bents, hinged to the lower chords of the trusses. These will rest on castings in a sub-pier at bottom of river. The trestle bents will rise with the bridge and fold parallel to the floor of the spans, leaving the full depth and 150 ft. width of stream clear of obstruction. This motion will be controlled by a positive automatic connection, independently of the weight of the bents.

Small hydraulic pressure pipes will be laid, as indicated, to the central sub-pier. Any silt drifting under the feet may be washed away by turning pressure on these pipes. The bents may be dispensed with if preferred, and the span supported by suspenders from the towers, as indicated on the plans.* This will increase the cost of the bridge.

Each span will be balanced by two cast-iron weights in steel frames running in guides in the frame work of the towers. These will be connected with the span by 12 1½-in. steel cables (six on each side), passing over two 10-ft. diameter steel riveted wheels, placed on top of the tower. The weights will be subdivided and the cables attached to them by equalizers with adjustable connections.

The cables will be connected to the spans by a system of links, so arranged that the counterweight, though constant, will balance the span in all positions, except near each end of the travel, where the position of the links is such as to cause the weight to act against the moving span and assist in bringing it to rest. This arrangement is shown by an explanatory diagram on the drawings.

On the ends of the spans are placed curved lattice buffers which will engage the cables should the spans pass the perpendicular line. These are so arranged that a wind pressure of over 30 lbs. per sq. ft. will not be sufficient to force spans against towers.

Each span will be operated by eight hydraulic rams, 12 ins. in diameter and about 8 ft. stroke, four for lifting and four for lowering. These will be supplied with pressure from a compound duplex pump. An additional duplex pump is provided to act as a relief for the compound pump and to increase the working pressure during high longitudinal winds. These will be automatically controlled by variable power hydraulic valves.

All hydraulic pipes, fittings and cylinders will be tested to 2,500 lbs. per sq. in., and will be so duplicated that the bridge will be capable of operation in the event of disabling of any two of either set of four rams or their connections. The rams are of sufficient size and strength to resist a longitudinal wind pressure of 30 lbs. per sq. ft. on the entire floor of the bridge. The arrangement of pumps is such that a range of hydraulic pressures may be obtained up to 1,200 lbs. per sq. in. Under average conditions the working pressure will be about 250 lbs. per sq. in. Mechanical automatic stops will be provided in connection with the operating valves, which will bring the bridge to rest gradually at the end of its travel. Hydraulic buffers will also be provided on the ends of the rams, for the same purpose, as an additional safeguard.

Hydraulic speed governors will be provided, by means of which the speed of the bridge will be controlled or limited independently of the operator. The operator may move the bridge as slowly as he may desire or stop it entirely at any point of its travel, but he cannot, nor can a puff of wind, increase the speed beyond the limit at which the governors are set.

The bridge may be operated in calm weather in 30 seconds and closed in the same length of time. Under average conditions the time would be about 45 seconds opening and 45 seconds in closing. The bridge may be operated directly by a man in the tower, or by signal bell to a man in the engine room, as may be preferred.

The plan includes suitable boiler and appurtenances, and the entire power apparatus is located in the foundations of the tower. If a supply of electric current is available, electric motors may be substituted for hydraulic rams and the boiler be dispensed with. We prefer a hydraulic plant for this class of work, considering it more reliable and certain in action, and less liable to derangement."

Fig. 2 shows a half-span of a structure designed by Mr. W. H. Breithaupt, M. Am. Soc. C. E, 71 Broadway, New York City. It is a three-hinged arch, made in halves, with the bridge floor suspended from it and hinged to it. The following is from the description submitted by Mr. Breithaupt with his design:

> The floor is in two parts and is hinged to the arch near its ends. The arch is made to part at the center point, and each half is arranged to revolve around its endpins. There are two towers, one at each end of the arch. Over the tops of the towers, and attached to the two halves of the arch at the center joint, are cables, by means of which the mid-stream ends of the floor and arch halves respectively are raised. The floor suspenders are stiffened pairs of eyebars, jointed at the center of their length so as to fold between the floor and the arch as the floor is raised. In opening the bridge the floor halves are first pulled up against the arch; then the arch parts, with the floor parts close against them,are raised to approach a vertical position against the towers. In many cases, such as to allow passage of single tugs or barges having no high projections, it will be necessary to raise the floor parts only, without disturbing the arch. When the bridge is open the roadway from either side is shut off by the bridge floor standing on end across it, and forming an effective barrier.
>
> There are two sets of counterweights, one for the floor, and a main set for the entire bridge. The floor counterweights are of constant counterbalance, consist of a single weight each, and operate, with the exception of a short-leverage pull afterwards, only in raising the floor against the arch. The main counterweights consist each of a chain of weights, suspended from the respective cables, and having its lower end attached to a fixed point. As the counterweight descends it gradually reverses and its weight is gradually and evenly, without shock of any kind, transferred to hang from the fixed point spoken of. This arrangement provides for uniform conuterbalance as the arch parts rise.
>
> The bridge is operated by means of electric motors, one in each tower, connected by a cable under water, and controlled from one switch by a single operator. The mechanism is so arranged that the two arms of the bridge move together and that one cannot get ahead of the other. The motors connect to the drum shafts by means of worm gearing, as an additional safeguard in regulating the movement of the bridge arms. The motive power may also be a steam engine in each tower, electrically controlled to operate synchronously. A hand winding arrangement is provided at each worm shaft, so that the bridge can be operated by hand power, in the very improbable case of this being necessary.
>
> The floor can be raised to the arch in less than 20 seconds and the full raising of the bridge can be done in 40 seconds. No locking of any kind is required, on closing, and therefore no time is taken up in this way.
>
> Forming the center joint of the arch, one arm has a convex end and the other a corresponding cavity with guide projections, which serve to bring the two arms to their proper bearings against each other. The surface of contact between the arms is, in vertical section, a little less than a vertical semi-circle, a slight revolution of one end about the other being provided for. This allows for expansion and contraction of the arch arms, without disarrangement of any part. To avoid shock on the coming together of the two arms, hydraulic buffers are interposed at the tops of the towers to check the main counterweights as they come to their upper limit of travel. Buffers are also placed at the points where the floor impinges against the arch, during the raising of the bridge.

Mr. Chas. E. Bedell, 156 Fifth Ave., New York city, submitted a design which is shown by Fig. 3. It is of the bascule type, and the outer ends of the two folding arms are supported by eye-bars from the towers. An important feature of the design is the support of the towers on cylindrical piers and the provision of a rear anchorage for the tower to a masonry abutment on the shore to take up the pull of the suspenders that carry the channel span. In order to vary the pull of the counterweight with the varying positions of the channel span, each counterweight will consist of a number of separate plates of cast-iron arranged to be supported on small brackets at intervals of about 2 ft. vertically in the height of the tower and to be picked up in succession as the counterweight ascends, or deposited as it descends. This is practically the same device that was used in the temporary drawbridge of the New York Central R. R. over the Harlem River.

---

*See Engineering News, July 9, 1896, pp. 24 and 26.

*By an error in our drafting department the dotted lines showing these suspenders were omitted from Mr. Brown's design.—Ed.

The bridge is to be operated preferably by a 50-HP. electric motor, in each tower, and 40 seconds is given as the time necessary to raise or lower the bridge. The dimensions proposed are a clear span of 150 ft.: lift-arms, 96 ft. each; fixed spans, 50 ft. each; height of towers, 112 ft. Travel of counterweight, 95 ft.; cross-section of counterweight well, 4 × 8 ft.

It will be seen that the eye-bar suspenders are attached to the channel spans at a point ⅓ of their length from the outer end and make an angle of 45° with the towers. They have a pin joint at the center permitting them to fold as the bridge is raised by the cable.

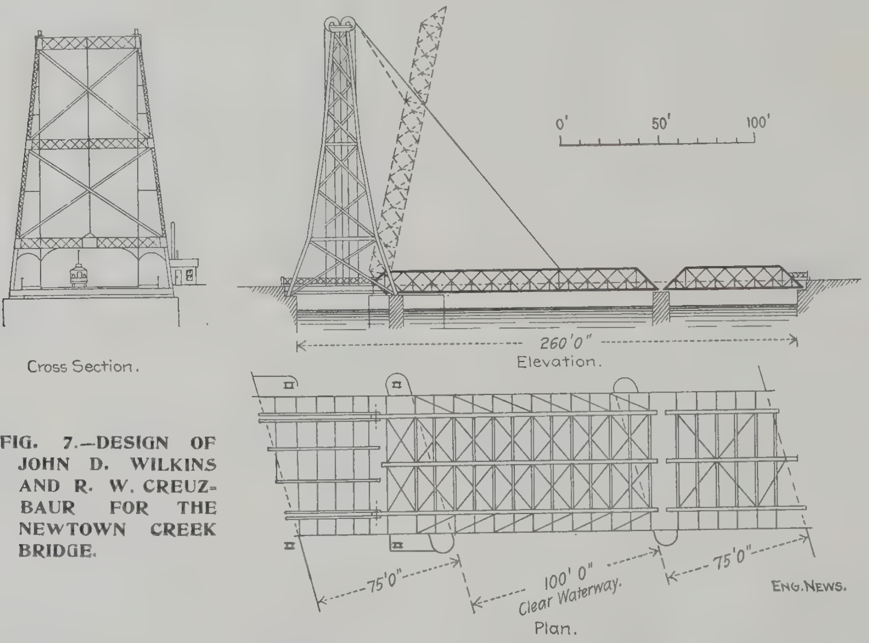

FIG. 7.—DESIGN OF JOHN D. WILKINS AND R. W. CREUZBAUR FOR THE NEWTOWN CREEK BRIDGE.

To operate the structure an attendant is required in the motor-house in each tower. Folding gates to close the sidewalks and roadway and operated from the motor-house are provided at each tower.

The design submitted by Mr. E. B. Jennings, 170 Florida St., Springfield, Mass., is shown in Fig. 4. It is also of the bascule type, but dispenses with towers, and a truss is used instead of a girder for the span. When the bridge is closed the top chords of the two halves simply butt against each other, but the bottom chord is made continuous by a pin joint. We quote as follows from the description furnished to us by Mr. Jennings:

> To open the bridge it is only necessary to withdraw this pin, when by means of suitable machinery at each end the bridge revolves vertically on the pivots and the channel is left entirely free for navigation.
>
> The ends are counterbalanced, and the gearing used may be similar to that of an ordinary horizontal swing bridge.
>
> At the center of the top chord there is a V-shaped projection at one end, and a corresponding depression at the other end serving to bring the bridge into proper position when closed. The eye-bars at the center of the bottom chord are placed an inch or two apart so that they may more easily come into place when the bridge is closed. The pin at the center of the bottom chord is made cone-shaped and the chord bars are bored to fit, thus allowing the pin to be more easily moved in and out.
>
> If the motive power is steam, the engine, boiler, etc., may be placed under the roadway, or electric motors may be used if preferred.
>
> Two subways are suggested to accommodate foot passengers while the bridge is open.

The design submitted by Messrs. F. S. Williamson, M. Am. Soc. C. E., and Alfred Liebmann, 50 Broadway, New York city, is for a lift bridge (Fig. 5), resembling in its general construction Mr. Waddell's Halsted St. lift bridge at Chicago. The chief difference is that these designers have curved the rear leg of the tower and have arranged to have the span raised and stopped at a level of about 30 ft. above low water to permit the passage of tugs, scows, etc., and still permit foot passengers (but not vehicles) to cross the bridge. Further, these designers propose to use gates to automatically close the roadway at each tower when the bridge is raised.

We have been favored by the designers with the following interesting discussion of the elements involved in the problem and the reasons for their selection of the design which they submitted:

> The Bridge Committee of Kings and Queens counties, having invited designs for this bridge at Vernon Ave., we commenced the study of the problem by at once visiting the site and seeing for ourselves the conditions we had to meet.
>
> We found in the first place that the majority of the people of Long Island City were in favor of a high level bridge, and that they had so publicly expressed themselves on more than one occasion. Also that this view of the case had been held and advocated by the "Brooklyn Eagle" for a long time past. The approach on the Long Island City site is crossed by no fewer than six tracks of the Long Island R. R., a most dangerous crossing, and it is not to be wondered at that the people using this bridge should advocate a raised approach thereto.
>
> We next found that the railway company was prepared to co-operate with the city in the building of a viaduct in connection with such a high level bridge, and moreover would surrender a portion of its yard for this purpose if required for a more gradual descent to the street level.
>
> The abolition of this dangerous grade crossing would be only in the line of the vast improvements going on in almost every large city of the country, at great cost to all concerned.
>
> The roadway of the bridge, if this plan were carried out, would cross the creek at such a height that all mastless vessels could pass under it, thus allowing the passage of seven-eighths of all the water traffic at this point. This is a matter not only affecting the owners of tugs and barges, and the shippers and manufacturers doing business along the banks of the creek, but the thousands of pedestrians and wagons crossing the bridge.
>
> The writers on one occasion stood at the entrance of the bridge for 15 minutes and in that time the bridge was opened no fewer than three times, and the gates at the railway crossing, not 300 ft. away, closed four times. The obstruction to street traffic was as serious as it was confusing, dozens of teams being hemmed in between the gates on the one hand and the open draw on the other. Now, if a bridge should be built which would allow seven-eighths of the water traffic uninterrupted passage, while permitting a free crossing for the thousands of pedestrians, a great part of the problem would be solved.
>
> It was feared. however, that the opposition of the property-owners would result in legal complications and long delays. The decision was therefore arrived at to abandon this part of the plan, owing to the urgent call for the new bridge at this point. Nevertheless the probability of this high level approach being called for at no very distant date, led us to believe that the bridge must be of such a character that it could be converted cheaply and expeditiously to meet this eventuality.
>
> Now that we were obliged by force of circumstances to give up the idea of a high level structure, the importance of having to close the bridge as seldom as possible to the very large number of foot passengers using the bridge, became evident. These passengers at certain times of the day are largely work people, going to or coming from their work, whose crossing should be obstructed as little as possible. This would be impossible if the bridge had to be lifted every few minutes for the passage of every tugboat or float.
>
> We think that our design offers a solution of the two important points herein enumerated; first, the inexpensive and ready manner in which the lift bridge can be changed to suit the future construction of a high level approach; and second, the importance of being able to raise the bridge to such a height as to admit of the passage of mastless vessels without interrupting the crossing of the large number of foot passengers.

The illustration on our inset sheet shows the construction which these engineers propose for the present. It will be evident that by merely placing column supports of proper height at the towers the bridge would become a high level structure whenever the necessary viaduct approaches may be built. The estimate of cost submitted by Messrs. Williamson & Liebmann was as follows:

Steel in superstructure, 1,290,000 lbs, at 4 cts...	$51,600
Lumber in floors, 60,000 ft. B. M., at $30.......	1,800
Operating machines, cables, weights, etc........	72,600
Substructure	74,000
Total	$200,000

A peculiar design, submitted by Mr. Chas. Steiner, 403 Bushwick Ave., Brooklyn, is shown in Fig. 6. It is a hinged lift span in two halves. Each half consists essentially of a principal compression member which is stiffened by trussing, as shown. When the bridge is closed these two compression members abut against each other and their thrust is transmitted to the abutments on each side. To raise and lower the leaves a segmental-shaped chamber is built on each abutment and a rectangular piston attached to and forming part of the bridge truss is moved to and from in this chamber by water, "at a head of 100 to 200 ft." Sketches were submitted, which we do not reproduce, showing a method of making this rectangular piston and the chamber in which it moves water tight, and "spray-guards of light plates protect waiting passengers from occasional escape of water."

Messrs. John D. Wilkins, 51 State St., Albany, N. Y., and R. W. Creuzbaur, Assoc. M. Am. Soc. C. E., submitted a design of which we received a drawing too late to include it on our inset sheet. It is, therefore, shown herewith (Fig. 7), while Fig. 8 shows a detail of the counterweighting system employed, which is the principal feature for which claims are made in this design. It will be seen by the drawing that the counterbalance, or a part of it, is in the form of a heavy chain, as in the design submitted by Mr. Breithaupt, but one end of this chain is attached to a cable passing over the pulley at the top of the tower instead of being attached to a fixed point as in Mr. Breithaupt's design. We quote as follows from the description submitted with the drawings:

> The movable part of the proposed bridge is a hinge bridge, firmly hinged at one end and lifted by means of steel cables to nearly a vertical position, to give a clear way for the passage of vessels.
>
> The bridge is designed with the Wilkins improved counter-balance, which has no loose parts, is noiseless in its operation and counterbalances the bridge with the greatest precision in any position it can take. Being so nicely balanced, it requires the least amount of power to operate the bridge, and on account of the steady motion of all the moving parts the bridge can be opened or closed with the greatest rapidity.
>
> A balanced-hinge bridge in motion requires a continually changing counterweight. In the original hinged bridge this change of counterweight was effected by releasing parts of the counterweight at intervals during the raising of the bridge, and in picking them up again during the lowering of the bridge. Only a rough approximation of the true counterbalance can be made in this way. The continuous releasing and picking up of heavy pieces of cast iron occasions severe blows, and requires powerful engines and a heavy tower. The motion of such a bridge must be slow to avoid destruction of machinery and structure. The Harlem River hinge bridge was built on this plan; it has to be operated slowly, but otherwise it works very satisfactorily.
>
> The Wilkins system provides for a continuous change of counterweight by connecting the separate parts of the weight in the form of an endless chain. A perfect counterbalance may be obtained in this way, the motion is steady,

without shocks and vibrations, therefore the maximum of speed is attainable. It is the simplest device of a changeable counterbalance known; it has no loose parts, is almost without friction, and it cannot get out of order. In addition to perfect balance and speed of operation, the Wilkins system of counterbalancing a hinged bridge requires less than half the power required for a vertical lift bridge, only one tower and no other substructure besides the bridge. It requires less machinery than any other kind of movable bridge. The operating engine occupies a space of about 6 × 8 ft.; besides this there are no other parts of machinery, no gear wheels, no shafting, no part of the structure or machinery is below high-water mark, and every part is easily accessible. The greatest care has been taken to select and combine only such devices as will insure immunity from repairs. All parts of the machinery and the wire ropes are arranged so that they can be replaced if worn out without interrupting for a minute the operation of the bridge.

The bulk of the counterweight is in stone ballast, contained in a box made of steel plates and angles. If at any time it is desired to put a heavier floor on the bridge, practically perfect counterbalance can be restored by adding more stone and adjusting the chains.

Fig. 8.—Details of Wilkens' Counterweight System for Bascule Bridges.

With this description an argument was also submitted respecting the advantage arising from quick opening in a swing bridge and from economy in operation. We reproduce it as follows:

> The difference in time of opening does not represent the total amount of time gained. A bridge-keeper finds it much more difficult to estimate the distance a vessel can cover in three minutes than in one. Therefore, in the latter case the vessel is far more likely to be ready to enter the channel as soon as opened; whereas, with a slow-opening bridge, the vessel is apt to be a distance off after the passage for it is clear.
>
> The gain of only two minutes semi-hourly during fifteen hours—a moderate estimate—amounts to a saving of one hour; an hour taken daily from a busy community complaining of the loss of every minute. Estimate the loss of time to all the waiting vehicles and pedestrians at only $20 per day, shows that a bridge which saves such time is worth to the city, at 5% interest, $120,000 more than any other bridge that does not save such time, every other qualification being the same. * * * *
>
> A saving of $10 a day in operating a bridge increases its value at 5% by $60,000.

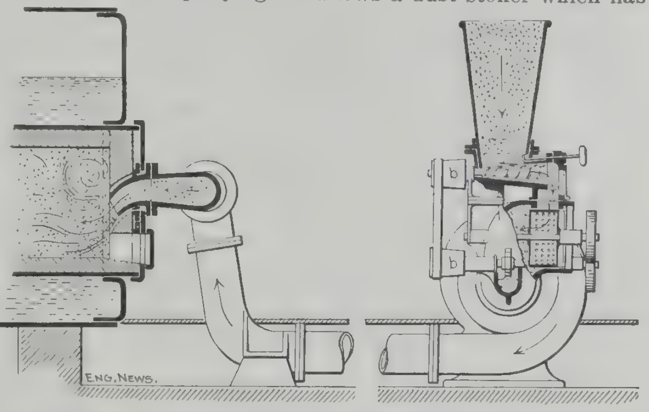
Messrs. Wm. W. Crehore, Assoc. M. Am. Soc. C. E., and Frank Miller, C. E., Havemeyer Building, New York city, submitted to the committee a design for a tunnel with an argument in its favor. We omit the design, but present the substance of the description submitted to the committee as follows:

> The chief objection always raised, whenever a tunnel has been proposed at this site, is the expense consequent upon having to reach back on either side of the Creek far enough to avoid impracticable grades. The accompanying plans have been prepared with the idea of reducing this item of expense to a minimum.
>
> Beginning at the intersection of 3d St. and Vernon Ave., in Long Island City, it is proposed to depress the middle of Vernon Ave. (for a width of 30 ft.) to a grade of 10%. for a distance of one block or to the north side of Ferry St., at which point the covered tunnel would begin. This opening in the street will, of course, be fenced in and the street curb will be moved back about 5 ft. on each side of the street to permit vehicles to pass along beside the opening. Thence passing under Ferry St. and the Long Island Ry. tracks with a grade of 5.3%, to a point 37½ ft. beyond the bulkhead line on the Long Island City side, the tunnel will have reached its lowest point. The War Department's requirement for a channel is 125 ft. wide and 18 ft. deep at low water. The proposed tunnel is level for a distance of 125 ft. in midstream and at such a depth that its highest point is 7 ft. below the War Department requirement above mentioned. Thence on the Williamsburgh side the ascending grade will be 6.7 ft. in 100 to Commercial St., whence a 10% grade continues to the surface of the ground one block away.
>
> It is proposed that the main section of the tunnel shall be composed of a steel frame and concrete arches 2½ ft. thick, so constructed as to be impervious to water. The clear height at the centre will be 14 ft. and the clear width 32 ft., which provides for a 20-ft. roadway and two 6-ft. sidewalks. An efficient system of drainage, including a small pumping plant, will be supplied. On the 10% grades at each end of the tunnel, the roadway will be widened to 32 ft., the sidewalk being discontinued before reaching this grade by providing stairways on either side for pedestrians. By increasing the width of roadway on these grades and by placing the car tracks at one side, a suitable track of inverted steel channel bars could be provided on the other side of heavily loaded vehicles going up. Vehicles entering the tunnel are to follow the entering car track, while those leaving may select either the up car track or the track especially prepared for them. This method will facilitate travel on the steepest part of the road and prevent delays. It is also proposed to provide an endless cable on this 10% grade, moving slowly at any desired velocity along the side of the wall about 3 or 4 ft. above the tunnel roadway, having rings at short intervals so that teams which need assistance in ascending the grade at the mouth of the tunnel may carry a hook and line to catch in one of these rings.
>
> Pedestrians will enter and leave the tunnel by easy flights of stairs located between Ferry St. and the Long Island Ry. tracks on the Long Island City side; and just north of Ash St. on the Williamsburgh side, These stairways will be 10 ft. wide to a platform about one-third the distance up and then shall divide in two stairways, each 5 ft. wide, leading in opposite directions. Two such flights of stairs will be placed at each entarnce to the tunnel, one on each side, as shown on plans. The capacity, roughly estimated, would be 15,000 to 20,000 pedestrians per hour in each direction.
>
> Method of Construction and General Cost.—There are several methods of constructing tunnels in soil which is of the nature of this soil and it would be a matter for contractors to figure on as to which method might be the cheapest and best. In proposing a steel frame and concrete arch lining for the tunnel, we considered that the coffer-dam method of construction would be the cheapest and that it would be possible to use it throughout the length of the tunnel. It would only be necessary to keep open a portion of the route at a time, and in view of the fact that the traffic would have to be turned aside over a temporary bridge, in any case, this should not be a serious objection. The cost of excavating, constructing the tunnel, and back-filling, including all contingencies, such as the removing of the old bridge pier on the river and setting up the old bridge as a temporary affair further up stream, we estimate would be in the neighborhood of $450,000.
>
> Advantages of a Tunnel.—The item of time saved to teams, pedestrians and street car traffic as well as to the traffic in the river itself, is something that cannot be accurately estimated, but can readily be imagined. With a tunnel instead of a bridge, the cost of maintenance would be reduced practically to nothing, and a continual stream of travel may be kept up in either direction, both on land and in the river. The one item of the cost of seven men (four by day and three by night) to attend the present drawbridge is worth, if capitalized at 4%, about $75,000. Practically the only running expense in connection with the tunnel would be a small pumping engine and one man to tend it.
>
> Any proposition to cross the river by a bridge at this point, which does not include a viaduct approach on the Long Island City side, leaves half the problem unsolved, inasmuch as the delay to traffic by crossing the Long Island Railroad tracks at grade is fully equal to any delay due to a drawbridge or lift bridge. The present proposition is to cross these railroad tracks below grade, and in addition to the saving of time thus made there is the advantage of absolute security from any accident from railroad traffic. This advantage accrues to the railroad company, as well as to the municipal government, inasmuch as they are practically secured against suit for damages due to accidents or loss of life. The railway people will also be relieved from the running expense of guarding this crossing. It seems to us in view of the advances being made in other states in the matter of abolishing grade crossings, that the time is not far distant when some legislation will be taken by the State of New York to compel the abolition of all grade crossings of whatsoever nature. In such an event, either a tunnel must be constructed similar to the proposed design, or a problem of much greater magnitude will present itself for solution. In either event any bridge across Newtown Creek at the level indicated by the present lay of the land would have to be abandoned.
>
> In addition to the advantages already enumerated, the adoption of the tunnel will provide much greater dock front on both sides of the river at the points now used for the bridge approaches.

◆

A GERMAN COAL DUST STOKER.

The burning of coal dust was taken up in this country a dozen years or more ago with a view to utilizing the culm or waste products of the anthracite mines in this way. Since it is now found possible to burn the culm as it comes from the breakers without further crushing or grinding, nothing has been done, we believe, toward the development of dust fuel burning. In Germany, however, the matter has been taken up and the accompanying cut shows a dust stoker which has been in successful use in Berlin for 18 months. The construction is evident from the drawing. The coal is ground in a mill and carried to the hopper of the stoker by a traveling conveyor. The rate of feed of the dust is regulated by a slide in the bottom of the hopper and also by the cone pulleys b b, which drive the feeding worm. The amount of air blown into the furnace with the dust is also regulated by a slide in the fan.



A STOKER FOR FIRING COAL DUST.
F. de Camp, Inventor, Berlin, Germany.

The apparatus is the invention of F. De Camp. The boiler which is working in Berlin is said to have shown the system to be durable and to require few repairs. The boiler flues are cleaned once or twice a day. The advantages claimed for the system are that it is an automatic stoker and forced draft combined; that combustion is complete and smokeless, even when the poorest grade of fuel is used; and that the system gives a high evaporative efficiency and is economical in operation. It will be noted that it has the advantage over automatic stokers of the ordinary type that no machinery is exposed to the fire.

THE COMMERCIAL UNION OF SAXONY, says U. S. Consul Monaghan, of Chemnitz, has issued its tenth annual report showing the progress made in building up a foreign trade. In this ten years the Union has sent out, at a total expense of $75,000, seven traveling commissioners to investigate trade prospects in Canada, Mexico, the West Indies, South America, Eastern Asia and South and East Africa. It has also circulated German and English catalogues, circulars and reference books in five languages, calling attention to the industries of Saxony. Since 1885 8,000 merchants have visited the sample rooms and 9,000 answers have been sent out regarding the standing of foreign firms. Sample orders to the extent of 13,000, and covering $1,750,000, were sent out and these secured business valued at $7,500,000 more. The union has 46 agencies in Europe and 53 beyond the seas, with a home membership of 504 business houses. This union is only one of a number in Germany, and Mr. Monaghan says that the 3,500,000 people of Saxony are "busy as bees" turning out all manner of products for the English, French and American markets. This ten years of Saxon experience should be studied and followed by American producers. Export organizations already in existence in New York and in Philadelphia will tell them how to profit by it.

ENGINEERING NEWS
AND
AMERICAN RAILWAY JOURNAL.

Published every Thursday at Tribune Building, New York. Entered at the Post Office, New York, as Second Class Matter.

London Agencies: Kegan Paul, Trench, Truebner & Co. (Limited), Paternoster House, Charing Cross Road; Sampson Low, Marston & Co., (Limited), St. Dunstan's House, Fetter Lane.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; 6 months, $2.50; 2 months, $1.00; Single copies, 15 cents. To all other countries in the Postal Union, add $2.08 per annum (4 cents per number) to above prices for postage. No club rates allowed. Mailing addresses may be changed at will by sending both old and new address. We shall be obliged if subscribers who fail to receive their papers promptly will notify us without delay. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 326 means that subscription is paid to the 32d week (that is the issue of Aug 6) of the year 1896; the change of these figures is the only receipt sent, unless by special request.

ADVERTISING RATES: 20 cents per line agate measure. Want notices, special rates, see page 22. Rates for standing advertisements sent on request. Changes to standing advertisements must be in hand on Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.

In the Supreme Court of Kings County, Mr. John Ireland is held personally responsible for the construction of his building which collapsed in this city, a year ago, and the jury returns a verdict of $10,000 against him for the loss of the life of one Burke in the suit brought by his mother. While this suit was also instituted against the two contractors, these latter were exonerated by the jury, which held that the construction was under the personal supervision of the architect, the direct agent of Mr. Ireland. While this finding will probably be contested, the tendency of similar awards would be to impose greater responsibility upon the owners of real estate, and to lead them to be more careful, both in the selection of their architects and their contractors. The lowest professional fee combined with the lowest bid for work to be performed would no longer be a safe standard for acceptance on the part of the owner and actual builder.

◆

The censure of Chief Engineer W. S. Moore, U. S. N., for the late grounding of the battle-ship "Texas" in Newport Harbor, carries with it a lesson not made sufficiently plain in the official finding of the board of inquiry. And that is that the whole accident was due to the lack of a sufficient number of trained steam engineers on board this important vessel, and that as a consequence both port and starboard engines at the time of the accident were in the temporary charge of unskilled and irresponsible men, one a naval cadet and the other the chief machinist. It is true that a remarkable chain of circumstances preceded the accident that could not have been foreseen. The dynamo broke down and put out the lights in the engine-room just as the ship was entering the harbor; this accident made it necessary for the Passed Assistant Engineer in charge of the starboard engine to leave his engine in the temporary care of a naval cadet. When the signal came to reverse the engines, the starboard engine stuck and the Assistant Engineer in charge of the port engine left his post to assist the naval cadet in handling the reversing gear; the chief machinist put in temporary charge of the port engine, meanwhile, failed to observe the working of the mechanical telegraph which was used in place of the disabled electric telegraph, and he kept his engine going ahead while reporting that he understood the signal given from the bridge. The Chief Engineer was at his post, but he could not see the indicator dials and know that the signals were being misinterpreted. The court ascribes the grounding to a combination of these causes and censures the engineers, while very properly exonerating from all blame the captain of the ship. The accident is a telling commentary upon the attempt of certain naval officers, not engineers themselves, to still further reduce the engineering staff, and to put the actual working of the costly machinery of our war vessels into the hands of machinists and other subordinates of no authority and limited training. With the proper officers at their proper posts the signals given from the bridge of the "Texas" would most probably have been obeyed and the grounding would not have occurred. But, by reason of two engineers having to attempt to do four men's work, both engines were temporarily left in the hands of men who blundered; for no particular cause other than that they were not equipped for the work entrusted to them. The accident is a further illustration of the fact that in handling modern warships plenty of well trained engineers are an absolute essential; and that the number on board each ship should be such that no emergency can call from his post the engineer in direct charge of any engine. It never pays, even in the United States Navy, to set a boy to do a man's work, though some officers think that this can be done with safety.

◆

A correspondent believes that we have been somewhat too sweeping in our note of timber and pile graving docks, as expressed in our issue of Oct. 22, and he questions the existence of timber dry-docks in England at all. Our chief arguments in favor of timber for this purpose were the cheapness of such docks as compared with either stone or concrete, their roomy proportions, which better facilitated work within them, their quick construction, and the fact that they could be protected against the marine worm, and against decay in the upper works, by a judicious use of concrete. There is one qualification, however, which we omitted, and that was in the location of the docks. In our country it is altogether probable that in the warm waters and damp weather of the South, a timber dock will decay faster than in the North (and the point may possibly be reached where the stone or concrete will be preferable). In the North, the stone dock is subjected to the attacks of frost, and this mischievous agency does necessitate, more or less, frequent and costly repairs, and the timber dock is, as a consequence preferable.

◆

Our statement above referred to contained a misprint as to the time occupied in the construction of the Puget Sound dry-dock. The original contract of Oct. 29, 1892, called for completion in 36 months; but a supplemental contract was made. on Dec. 10, 1892, for lengthening the dock 50 ft., with an extension of time amounting to 3½ months, or 39½ months in all. But notwithstanding the added work the dock was finished in about 33 months; not 43 as printed. The timber dry-dock at St. Johns, Newfoundland, was completed in 13 working months; the timber dock at Norfolk was built in 21 months and the Newport News and the League Island docks each in 24 months. As to the actual experience with timber dry-docks in the United States, it may be stated that the oldest Simpson dry-dock was built at East Boston, and finished in November, 1854; another was constructed there in 1855, and a third in 1864. These docks are practically in good condition at the present day. The two timber docks at Portland, Me., were built in 1868-70. Concerning the use of timber for dry-dock construction in England, our correspondent is referred to a valuable chart on the "Dry Docks of the Thames," issued in 1882, by Mr. Charles James Jordon, M. I. N. A. This chart, in book form, covers all the dry-docks on the Thames, at that date, 41 in all. Of this total, in 1882, 6 were all wood, only 7 were all masonry, and 28 were partly of wood. Unfortunately the date of construction is not given for these several docks; but the fact that some of the all-wood docks are of small dimensions, and are closed by the old-fashioned wooden gates would point to a very early construction. These wooden docks, however, are unlike the type now built in this country, in being unprovided with altars, or steps, and in having vertical side walls of timber. Some of them have wooden bottoms and wooden gates with brick side walls. The important fact, however, is that timber has long been used for this purpose in England, and that many of these timber docks were still in use upon the Thames a comparatively short time ago.

◆

The results of the tests of the Roebling system of fireproof construction, in which a concrete arch, strengthened with steel rods, constitutes the floor support, will, we think, be a surprise to those who have not known hitherto the value of concrete as a fire-resisting material. That an arch of this construction of 4 ft. span, only 3 ins. thick in the center, could support a floor loaded with 150 lbs. per sq. ft., while a fire was kept under it for five hours, reaching a temperature of above 2,300° F., or beyond the melting point of copper and even of cast-iron, and then after this heating and sudden cooling by a stream of water could withstand a load of 600 lbs. without fracture, would, we think, be considered highly improbable had it not been proved by these tests. The competitive test between an arch of concrete and one of hollow tile, in which the latter failed, is one of the most important contributions to our knowledge of the ultimate resistance of fireproof floors which has been made for many years. The manufacturers of tile floors will no doubt have something to say in their own behalf in regard to this test, for it was not an official one, but as the matter stands it looks as if the concrete men had shown that in fire-resisting qualities their construction is at least as good as that which has heretofore been accepted as the best standard construction.

◆

THE DESIGN OF MOVABLE BRIDGES.

The designs for a movable bridge over Newtown Creek, at Brooklyn, N. Y., which are presented on our inset sheet in this issue, are interesting not only as respects the solution of the problem presented in this especial case, but as evidence of departures in the construction of movable bridges from the long-time standard swing span, which deserve the careful attention of engineers.

It is true in engineering work as in every other industry, that the force of precedent and custom is exceedingly powerful, and often leads to the adoption of a certain pattern or type of structure or machine, not because it is the best that could be devised or that is offered, but because custom has sanctioned it, and anything else is an innovation. In the especial case before us it has come to pass that the swing bridge is accepted without question as the proper means of carrying a road over a navigable waterway. Only within the past dozen years have any notable instances been furnished of exceptions to this general rule.

It is of interest to trace the process by which the swing bridge came to be the standard type of construction. The original drawbridge was not a swing bridge at all, but a lift bridge. In the centuries preceding the modern era, practically the only place where movable bridges were used was in crossing the moat that surrounded a castle or fortress. For this purpose a simple floor, hinged to a tower on the inner side of the moat and drawn up to a vertical position when the bridge was opened, was the type of structure in general use. The floor of the bridge when opened was an admirable barrier against enemies who might succeed in crossing the moat. The under-side of the bridge was sometimes covered with iron to prevent an attacking party from cutting it away.

Of course the openings which all such spans covered were of trivial width. Not until the art of building timber trusses was developed was it possible to bridge any stream of considerable breadth with a fixed span even, much less a movable one. With the advent of timber trusses, however, it for the first time became possible to throw structures across navigable streams of some size, and then the problem for the first time was presented of providing a passage both for vessels and for the bridge traffic. While various structures of the bascule type were devised for narrow openings, the spans to be moved soon reached such dimensions that with the hand power which was alone available at that day, the only course open was to build the span on a center turntable, or pivot, and revolve it in a horizontal plane. When iron and steel construction took the place of timber, it was entirely natural that the wooden swing span should be copied in metal.

It is only within very recent years, since the necessity of bridging waters which carry a busy traffic has arisen, that the defects of the swing bridge have become apparent. For all crossings of any considerable width, and where the water traffic is inconsiderable, it is doubtless true that the swing bridge is the best possible type. The structure itself is as stable, if properly designed, and erected, as a fixed span; and, aside from the machinery for turning it, it costs but little more. But when we come to narrow channels, and especially those where a large traffic is moving, the swing bridge is no longer so satisfactory. In a narrow channel, a center pier with the necessary draw-rest forms a serious obstruction to navigation. The time required to open or close it constitutes a delay to the traffic both over and under it. The swing of the arms necessitates keeping a considerable of the channel unobstructed and may in some cases make unavailable for docks, etc., valuable water-front adjacent to the shores. The liability to accident through collisions with passing vessels is considerable, and such accidents sometimes not only disable the bridge, but leave it in such a position as to stop passage through the channel. The danger to the traffic using the bridge, when the bridge is open, has been made familiar by a long series of distressing accidents. It is doubtless true that no structure could prevent a runaway team from dashing into an open draw; but it is quite possible that the elevated floor of a bascule bridge would prevent an electric car from taking such a fatal plunge as occurred at Cleveland less than a year ago, and it can be made to form a barrier which is a certain protection to ordinary foot and vehicle traffic.

We may add to this that the swing span thus far is the despair of those with a regard for the aesthetic in bridge construction. Its development thus far has been strictly on the lines of maximum strength with minimum material, and the resultant form, while undeniably correct from an engineering point of view, is a most awkward and ugly monstrosity to an artistic eye. There may be some method by which a swing span may be made a graceful and pleasing structure, but so far as we are aware, it has not yet been discovered. While this consideration in many situations will be considered of no importance, the tendency is all the time growing toward the requirement of some features of architectural merit in the bridges of city streets; and in locations adjacent to public parks or the choice residential sections of large cities this matter may often have more weight than anything else in selecting the design for a structure.

Turning now to the types of movable bridges other than the swing span, they may be classified broadly as straight lift bridges, pontoon bridges, rolling bridges and folding or bascule bridges; each of these classes, the latter especially, including a great variety of designs. The straight lift bridge is simply an ordinary bridge span with cables attached at each end passing over towers and with a counterweight attached. To open the bridge the span is lifted straight upward. The pontoon bridge explains itself by its name. The rolling bridge is mounted on wheels running on a track and rolls straight back in the direction of its axis to open the channel. The bascule bridge is a bridge in which the floor lifts or revolves backward toward the end of the span to open the channel.

Some interesting examples of these various types of construction were furnished by the competitive designs for a draw bridge over the ship canal at Duluth, Minn. (Eng. News, Oct. 27, 1892.) Of the 12 designs presented in this competition, one was a straight lift, two were pontoons, six were rolling draws, and only one was a bascule bridge. The other two were swing bridges with unequal arms, and pivot piers on the shore, the ends of the long arms meeting in mid-channel.

The straight lift bridge has the merit of simplicity; but its reputation has been somewhat injured by several unfortunate accidents which have befallen the only prominent example of this construction, the Halsted St. bridge at Chicago. From the experience there it would appear that to make this type of bridge a success the greatest care must be given to the operating machinery in every detail, and it should be so designed as to make the failure of the mechanism so as to stop the working of the bridge an exceedingly remote possibility. This type of bridge is rather expensive to operate from the fact that the entire weight of the span must be lifted. It leaves the streets unprotected when it is raised unless an additional provision of automatic gates is made. On the other hand it may be made a very handsome structure, and an especial advantage in the case of the Vernon Ave. crossing is the ease and economy with which changes in its height may be made to suit changes in the street level.

The pontoon bridge has never been actually used where frequent and rapid opening and closing were essential. Some interesting designs which contemplated this were submitted in the Duluth competition, but it is doubtful whether rapid opening and closing could ever be attained by this type of structure. The fact that it has to swing against the traffic, moving in one direction, increases the amount of delay necessary and it will be evident that it is worse than a swing bridge with respect to its obstruction of the water front, and the sweep of clear water that it requires. It may also be pointed out that it is essentially a low-level structure, whereas a movable bridge over a busy stream ought to have its normal level far enough above the water to permit the passage of most mastless vessels without opening the bridge.

Rolling bridges are chiefly objectionable because of the space required by the structure when it is drawn back on shore to open the channel and for the complication in approaches which is necessary. In the case of a double rolling bridge, the ends meeting in mid-channel must be locked together to make a continuous truss, as it is hardly feasible to provide counterbalance on the shore arms for live load. Existing examples of rolling bridges are of very small span, so far as we recall.

The folding, or bascule, bridge has been built in a variety of types during the past few years, and is at present, with the exception of the swing bridge, the most popular type of movable bridge Some of its popularity may be due perhaps to the success of the noted Tower bridge in London. It is certainly remarkable that in the Duluth draw bridge competition of 1892, only one design out of 12 was of this type, whereas in the Newtown Creek competition, six out of the eight designs are for a structure of the bascule type.*

The advantages of the bascule type of movable bridge may be enumerated as follows: It leaves an entirely clear channel.; it interferes with no dock space adjacent to the towers; it requires less power to operate it than any other type of structure, the average lift being only half (or a quarter) that of a straight lift bridge, and one end being supported at the tower. The span itself may be made to furnish an automatic barrier across the roadway when the bridge is opened. It can be opened and closed very quickly, and in its motions takes no space in the channel as do all classes of swing bridges. Its towers enable the bridge to be made a very graceful and ornamental structure, wherever this is a consideration.

Of the various types of bascule bridges that have been devised, the least expensive, when the cost of operation is considered, is probably the type with a single moving leaf spanning the entire channel, of which the design of Messrs. Wilkens & Creuzbaur is an example. A single operating-house moves this bridge, and with bascule spans, meeting at the center of the channel, it is not yet demonstrated that operating machinery on each side of the channel will not be necessary. It may be objected that this type of bascule leaves the roadway open at one end when raised, but it ought not to be difficult to provide automatic gates at this end worked by the raising of the bridge. Of course, for very long spans, the truss would become very heavy to handle; but for spans of moderate length, it appears to be a very promising type of bascule.

Of the bascules with arms meeting in mid-channel, a variety of types are shown on our inset sheet. Two classes are represented, those in which the span is made continuous by connecting the lower chords of the two halves when the bridge is closed, and those in which the floors and their loads are carried entirely on suspenders from the towers or from an everloaded construction. With the first class the tower may be made very light, or may even be dispensed with altogether; but the truss itself must of course be made considerably heavier, and the connection of the lower chord might prove rather complicated.

A problem of some interest in connection with the bascules supported by inclined suspenders from the towers is the method by which the two parts of the span will be kept at the same level at the center when a heavy load crosses. It will be seen that the weight of the span itself is balanced by a cable running to the counterweight. The office of the eye-bar suspenders is to support the live load, and they will evidently hang in a considerably flatter curve when the bridge is loaded than when it is empty. It will probably be necessary to provide locking gear to keep the abutting ends at the same level.

The problem which has been solved in the greatest variety of ways is the method of counterbalancing the span uniformly in all its positions. Several different plans of affecting this are shown in the designs on the inset sheet. The system in which the counterweights hang in a chain, which transfers its weight to a fixed point, or to the other side of the head sheave as the span moves, seems to promise especially well for smooth and rapid working.

The question of the best power for operating a movable bridge should have but one answer at the present day, the electric motor, in any city where a reasonably certain supply of electric current is obtainable. The only objection to it is the possibility of failure, and this is very small at the present day. Of course all movable bridges should be fitted with hand gear for moving in case of failure of the power machinery in any event, and in a very important structure an emergency steam plant with a fire-engine boiler might also be installed. The actual amount of time that is occupied in moving a bridge even over the busiest streams, is so small that the amount of power actually used is very small. With an electric motor there is no expense for power save when the bridge is actually moving, and what is of more importance, the bridge operator has nothing to do but move a switch and can give his undivided attention to the movements of vessels and traffic.

As most movable bridges require attendance both day and night, the ability to operate them with a small force is a very important matter; the saving of the wages of one or two men per shift will pay the interest on a large sum of money. It is worth noting that lift bridges, in which the operating machinery is on the shore, are better adapted to operation by electric power than swing bridges where the machinery is on a pier in the stream and the current must be carried to the pier by cables under water, which are liable to be fouled by passing vessels.

Space forbids the discussion of other interesting questions in connection with the subject, such as to the comparative first cost of swing span and bascule structures; but it is hoped that what has been said may lead to a better appreciation of the merits of movable bridges other than the swing span. The design of every bridge should be a matter of study in connection with the local conditions and a swing span should not be adopted where a movable span is necessary unless it fulfils the requirements better than any other type.

---

*For drawings and descriptions of recent bascule bridges, see Engineering News, May 23, 1891; Dec. 14, 1893; Jan. 18, 1894; Feb. 21, 1895, and March 7, 1895.

LETTERS TO THE EDITOR.

Early French Movable Dams.

Sir: Can you refer me to any descriptions of the primitive movable dams used in France, say prior to 50 years ago, and of the Thenard shutter?

Very truly, "Barrage."

State College, Pa., Oct. 28, 1896.

(In the "Proceedings of the Institution of Civil Engineers," Vol. LX., p. 24, will be found a paper on "Fixed and Movable Weirs," written by Mr. L. F. Vernon-Harcourt, M. Inst. C. E. This paper describes the Poiree needle-weir, of 1834, the movable shutter of M. Chanoine, and the drum-weir, bear-trap weir, segmental gate weir, rolling shutter and the various hydraulic shutter weirs, all used in the improvement of the River Seine. The needle-weir, which seems to have been one of the earliest forms, was made up of a series of needles, or bars, 11½ ft. long, and 3 ins. square, furnished with hooks by which they revolved on the top-bar of a supporting trestle of iron work. They were used side by side with shutter weirs and were regarded as simpler in construction, more easily moved and less liable to get out of order than the early types of shutter weirs. The Chanoine shutter or wicket was introduced upon the Seine about 1860. Our correspondent is also referred to the published work of Mr. Vernon-Harcourt on "Rivers and Canals." We regret to say that we can give no detail of the Thenard shutter.—Ed.)

◆

A Puzzle in Mechanics.

Sir: A problem in mechanics recently given to the students here has attracted considerable attention and aroused no little enthusiasm. I take the liberty of stating the problem and asking that you give your solution:

"A man stands on a perfectly level, solid and frictionless table, large enough so that he will not fall off. Nothing but air surrounds him and he has nothing to throw. How can he get off the table?"

Of a number of answers given, the most sensible were, that he could swim off or blow himself off. But when action and reaction are considered, even these seem impossible solutions. Of course a quick exhale would produce some motion, but the inhale would also tend to move him back to his original position, and so with his hands if used as in swimming. When he threw them out he would move nearer his destination, but when he drew his hands back again would he not tend to move toward his original position? Again, is it possible for him to turn his head, even slowly, without a movement of his feet?

You will note that the problem brings up a number of complicated questions, and I hope you will give me your idea.

Very respectfully yours,
Chas. W. Gennet, Jr.

Chi Psi Lodge, Ithaca, N. Y., Oct. 29, 1896.

(The man could blow himself off for he could inhale vertically, through the nostrils, which would produce no horizontal reaction, while he could exhale horizontally through the mouth. He could also inhale slowly and exhale rapidly. He could also get off by a swimming motion, for he could move his hands in one direction while they were placed so as to cut the air, and turn them to act as paddles against the air before moving them in the opposite direction. We think he would not be able to turn his head without moving the rest of his body, for the motion is produced by contraction of some muscles in the neck, which would act at both ends, pulling the head in one direction and the body in the other.—Ed.)

◆

Wright's "Element of Mechanics,"

Sir: In the review of my "Mechanics," contained in Engineering News of Oct. 22, the reviewer advances views which to say the least are misleading.

1. The reviewer takes to task writers who do not follow the methods of twenty years ago, but introduce innovations.

The answer is not far to seek. The Mechanics of to-day, unlike that of twenty years ago, is not for the civil engineer only. The electrical engineer and physicist have come to the front in the meantime. They must have a notation and units as well as the civil engineer. His are not sufficient for the reasons stated in the book (p. 62), Hence to the gravitation system of units is added the absolute system, and hence the new terms micron, megadyne, kilo-watt, barad, etc. Hence, too, the theory of dimensions at which the reviewer sneers. Without an account of the theory of dimensions any book on Mechanics is antiquated.

The introduction of new terms is, therefore, to be looked for mainly* in a region in which the civil engineer has hardly any concern. And by omitting to read the last chapter he may never meet them. At least the reviewer has found nearly all that excites his ire in the domain of the physicist and electrician.

The terminology given is that of the best authorities, the British Association Committee and the International Electrical Congress held at Chicago in 1893. I have been careful not to add anything as I am as much opposed to terms not authorized as is my critic.

2. Twice my attention is called to the absence of the relation

$$M = \frac{W}{g}$$

or mass is equal to the quotient of the weight by the factor g.

This is found in all the old books and has, I venture to say, been a source of endless confusion. Its elimination marks a great advance.

The factor g is introduced to change from an absolute to a gravitation system, or vice versa (p. 60). When this is understood the question "whether shall I multiply or divide by g" is answered.

3. In order not to make this letter too long I will not enter upon a discussion of the questions raised regarding force and energy. The definition of force laid down is that given by Newton in his first law of motion and is not a verbal hair-splitting by any means.

It would seem that, after all, progress in Mechanics is possible—in fact modern physics is rapidly assuming the form of a dynamical problem.

T. W. Wright.

Schenectady, Oct. 27.

The Economy of Steam Shovel Work.

Sir: In your issue of Sept. 24, you give in detail the bids on the "Nashua Aqueduct," for the new Metropolitan water supply. These bids make an interesting showing of the advantage which any contractor has who uses steam shovels for work of any magnitude. The successful bidder on this work has been using a Vulcan "Little Giant" steam shovel and based his bid on what he knew could be done at a profit. The work comprises 290,000 cu. yds. of earthwork and stonework of different kinds. There were 21 bids opened, and the totals ranged all the way from $86,960 to $401,275, quite a difference. The lowest bid was rejected. The next lowest and successful bid was $89.470. In this bid the 290,000 cu. yds. of earthwork were priced at 18 cts. per cu. yd.

I give below a statement in detail, showing how much lower than the successful bid each one would have been if each had figured the earthwork at the same price (18 cts. per cu. yd.) Strange as it may seem, the highest bid, $401,275, if figured at 18 cts. (the lowest price), would have been $12,995 lower than the successful bidder. It was actually $324,800 higher on the excavation.

Yours truly,
The Vulcan Iron Works Co.,
Alex. Backus, President.

Toledo, O., Oct. 26, 1896.

Table Showing the Effect of High Estimates for Earthwork in Bids for Nashua Aqueduct.

Bid No.	Price per yd. over successful bid, cts.	Excess on the earthwork.	Actual total bid.	Had each bid been 18 cts. per cu. yd. on earthwork, the bids would have been:	
				For whole work.	Or less than successful bid by.
1	3	$8,700	$86,960	$78,260	$11,210
2	...	.....	89,470	89,470	......

Salinas Bay as a Pacific Terminus for the Nicaragua Canal.

Sir: I notice in your paper of the 8th inst., a letter from Mr. Sylvanus Miller, M. Am. Soc. C. E., in which, among other things, he advocates a survey of the Salinas Bay route for the Nicaragua Canal, on the west side of the isthmus. It is undeniably the fact that the surveys made by the Nicaragua Canal Construction Co. were too much confined to one route, but I must take exception to Mr. Miller's assertion that the surveys on the Salinas Bay route were not thorough and complete enough. It must be remembered that we went out there for the purpose of locating one of two predetermined routes, and not, like a government expedition, for the purpose of exploring the isthmus. That had been done previously by the U. S. Government, by the Government of Nicaragua and by various private companies and persons; and as a matter of information I will inform Mr. Miller that a survey of the Salinas Bay route had been made by Col. Childs, in 1851, and by the parties under command of Commander Lull, in 1874.

However, the first thing that I did after being placed in charge of the Nicaragua Canal, was, in obedience to orders from the chief engineer in New York, to send one of my assistants, with a full field party, to Salinas Bay, to make a careful survey of this route and settle the question; which, by the way, had been twice settled before. I always supposed that this survey was ordered to appease the Costa Rica Government, in whose territory it lay, and who naturally wanted the canal terminus in their republic, if possible.

Be that as it may, my assistant, Col. Perez, went to Salinas Bay and started the survey toward the lake, and a copy of his report is before me. Before they had proceeded three miles they attained an elevation of over 800 ft., and were confronted with perpendicular rock cliffs, which they could not scale without making a great effort. They examined the country thoroughly, all about the bay, and this was the best line they could find. It was intended to take the line down the valley of the Sapoa River, an insignificant stream, emptying into the Lake Nicaragua, or any other that could be found that would better answer the purpose; but upon receiving his preliminary report, it was seen to be utterly impracticable, as much as we would have liked to utilize the fine harbor of Salinas, and I therefore recalled the party.

While the Salinas Bay line is unfortunately impracticable, I will say that I know that a better line, more economical and more practicable by far than the line selected by the Nicaragua Canal Co. does exist. It is thoroughly known to me, and I have personally examined it; a line that will do away with the immense divide cut and most of the other objectionable features of the line we were sent out to locate, and which had previously been selected by the company. If I had been sent out there by the company to find and locate a line across the isthmus that would be the best and most practicable and least expensive, I should certainly have selected the line referred to; we were not, however, sent out for any such purpose, but to make the best and most thorough location on the route previously determined upon, which comprised the high and low level lines that we surveyed, and I found by experience that any suggestions in regard to other routes were not received with favor.

In regard to the line that we did locate, I venture to say from an experience of over 25 years on public works that no public work ever projected, and I make no exceptions, ever had more complete, thorough and careful surveys, examinations and studies than the upper route of the Nicaragua Canal; and if the U. S. Commission had seen and examined all of the surveys, preliminary and trial locations, reconnaissance and fly-lines, cross-sections, check and counter-check levels, measurements and gaging of streams, determinations of river slopes and oscillations, soundings and borings, rainfall records, barometric levels, lake oscillations, etc., etc., they would have been forced to the same conclusion. But from reading their report, it would appear that the half of the data collected and forwarded to the home office by myself and my predecessor, Lieut. Peary, had never been collated and placed before them.

J. Francis Le Baron.
Late Principal Assistant and Division Engineer in charge,
Nicaragua Canal.

Jacksonville, Fla., Oct. 9, 1896.

TESTS OF THE ROEBLING FIREPROOF FLOOR.

In our issue of Sept. 17, we described a test which was made in New York city, on Sept. 3, of a fireproof floor constructed by John A. Roebling's Sons Co. A description and illustration of the system of construction, and of earlier tests upon it, was given in our issue of July 18, 1895. In that test the floor was subjected to a hot fire for two hours, and was then cooled by water, and found to be uninjured. As a protest sent to the Building Department of New York city claimed that two hours was not a sufficient time for a thorough test, it was decided to have a second test for a period of five hours. This test took place on Oct. 28, and its conclusion was witnessed by a member of the staff of this journal. Invitations had been freely sent out by the builders, and a large crowd was present, including many engineers and others interested in fireproof building construction. The test was made in the same building that was used in the former test, its location being an open lot at 81st St. and Western Boulevard. It is a steel skeleton brick structure, built after designs of Mr. G. C. Henning, the expert of the Department of Buildings, who also was in charge of the test. The size of the test structure is 12×16 ft. in area, by 12 ft. high. The floor was made of 10-in. I-beams, 25 lbs. per ft., 15 ft. 6 ins. between supports, spaced 4 ft. apart between centers, with concrete arches 3 ins. thick at the crown sprung across the beams. The concrete was made of 1 part Aalborg Portland cement, 2 parts sand and 5 parts ashes, from steam boiler furnaces. A filling 2 ins. thick was placed between the nailing sleepers, consisting of a concrete made of 1 part Aalborg cement, 2 parts sand and 10 parts ashes. A ceiling was placed under two-thirds of the floor, made of wire netting and lime plaster furnished by the United States Mortar Supply Co. The remainder of the floor was left unprotected. The floor arches were concreted on Sept. 26, and the ceiling plastered on Sept. 30 and Oct. 1. A grating extending over the entire floor area was fixed at about 3 ft. above the ground, and on it was placed a 2½-ft. layer of dry hard cord wood, sprinkled with oil, so as to cause it to ignite readily. A second grate about 2 ft. below the first was also supplied with fuel with the object of heating the air entering the building and thereby creating a higher final temperature. Before the test the central panel of the floor was loaded with brick to 150 lbs. per sq. ft. The test was begun by lighting the cordwood, at 10.06 a. m. The temperature was measured and graphically recorded by a Uehling & Steinbart pyrometer, which worked perfectly throughout the test. Some of the temperatures recorded are the following:

---

*Mainly, but not wholly, as for example, torque and horse-power-hour.

Time.	Temperature.	Time.	Temperature.
10.40 a. m.	1,100°	1.03 p. m.	2,050°
11.00 "	1,450°	1.33 "	2,050°
11.20 "	1,725°	1.55 "	2,125°
12.00 "	2,000°	2.11 "	2,050°
12.23 p. m.	2,100°	2.28 "	2,100°
12.43 "	2,300°	2.51 "	2,000°

From 11.55 a. m. to 2.51 p. m. the temperature was never less than 2,000°. This is a more uniform range of temperature than has been obtained in any of the previous tests by the Department, or in any other fireproofing tests ever made, so far as we are aware: At 3.06 p. m., a strong stream of water from a fire engine was thrown directly against the underside of the floor. When the structure had been sufficiently cooled, and the steam cleared, so that the floor could be inspected, it was found that the ceiling of wire netting and plaster had disappeared, but the arches were to all appearances uninjured, and the floor sustained its load. The maximum deflection of the roof before the water was put on was about 4 ins. On the next day the load on the roof was increased to 600 lbs. per sq. ft., which load was sustained without any signs of failure.

A comparative test of the Roebling system and ordinary hollow tile flooring was made on the day preceding the official test above described, in an adjoining structure. We abstract the following from a printed statement issued by the John A. Roebling's Sons Co.:

On Sept. 3 a comparative fire and water test was made in the smaller of the two brick structures at 82d St. and Western Boulevard, New York city. Two fireproof floor arches had been built in the structure, about 8 ft. above the ground, one according to the Roebling system; the other, an ordinary sectional hollow brick flat arch. A concentrated load of common brick, weighing 9,000 lbs., was distributed over about 15 sq. ft. near the middle of the arch. A hot fire was started and maintained underneath these arches for about an hour and a quarter, after which the water was turned on by a detachment of the Fire Department. After the fire was extinguished, it was found that both arches had sustained the test without apparently any damage other than the displacement of some of the plaster and a slight deflection of the hollow brick arch.

It was claimed by some of the persons present that the test was without significance, and that to have any value, the arches should be fired until one or the other failed. Acting on these suggestions, the ceilings of both arches were replastered on Oct. 1. A second fire and water test of these same arches was made on Oct. 27. Pig iron weighing 10,000 lbs. was piled over an area of about 7 sq. ft. in the center of each of the two arches, making a superimposed load of over 1,400 lbs. per sq. ft.

At 10.00 a. m. the fire was started.
- 10.30, the white coat of plaster off in many places, and at others, clinging to ceiling.
- 10.50, plaster still intact under both arches.
- 11.45, rough plaster of ceiling still intact under both arches. Copper plug for indicating temperature not fused.
- 1.00, rough plaster still in place; copper plug not fused.
- 1.35, copper plug fusing.
- 1.50, cracks beginning to form around load in hollow tile arch.
- 1.55, cracks opening parallel to wall and adjacent to it along both arches. That portion of the hollow-brick arch directly under load slightly depressed below level of the remainder of arch. Joints opening and smoke issuing around load on flat arch.
- 2.05, load over flat arch dropped through suddenly to the ground inside the brick structure.

Iron work erected Aug. 10; Roebling arch concreted Aug. 11; flat arch erected Aug. 10 to 11; first fire and water test Sept. 3; ceilings replastered Oct. 1; thickness of crown, Roebling arch, 3 ins.; depth of hollow brick arch, 10 ins.; size of beams, 10 ins.; 25 lbs.; spacing of beams, 5 ft., center to center; proportions of cement mortar used in setting flat arch, 1 part Aalborg Portland cement, 1 part sand; proportions of concrete used in Roebling arch, 1 part Aalborg Portland cement, 2 parts sand, 5 parts steam ashes.

This test was an unofficial test, but was witnessed by several members of the Department of Buildings as well as a number of others interested in the subject of fireproofing.

◆

THE VILLA BRICK MANTLE, FOR PROTECTING RIVER BANKS FROM EROSION.

Signor Giovanni Villa, of Milan, Italy, has invented and now tested for some years a system of protection for the banks of rivers and canals that is simple and cheap and certainly possesses meritorious features. This protective device is a mantle made of perforated bricks of terra-cotta or cement strung upon galvanized iron wire and connected laterally, between each row of bricks, by a strip of wood. The bricks vary in dimensions so as to break joints, as shown in Fig. 1. Mr. Villa has designed a special apparatus for making the mantle and for putting it in place on the river bed.

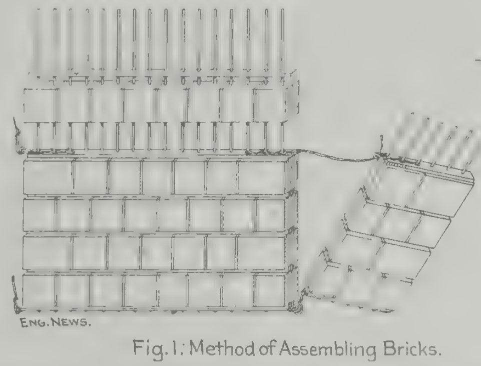

Fig. 1.—Details of Construction of the Villa Brick Mantle for Protecting River Banks From Erosion.

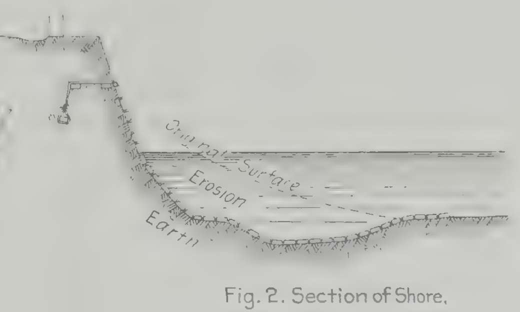

Fig. 2.—Cross Section Showing the Mantle in Place.

The mantle is applied to an eroding river bank in sections varying in width from 5 to 10 ft. with the character of the work; but these strips are also united together by wire at intervals, as shown in Fig. 1, and are anchored to the shore above the water-line. The resulting mantle, or covering, is strong and flexible, adapting itself to the conformations of the river bottom and extending from any desired point in the river to the bank. It is quite smooth and permits the water to flow easily over it. The inventor makes the following claims for this mantle: Cheapness, as compared with other methods of accomplishing the same end; great efficiency and duration; and rapidity and ease in making and laying. There is no obstruction to the normal flow of water in the river, and the deposit of fine mud carried into and behind the mantle only tends to give it greater permanence.

As to the important claim of durability, it seems that the first mantle was tried about five years ago on the River Olona, near Milan. Here a dike protecting some agricultural lands from inundation was faced for a distance of about 3,000 ft. on the Villa system. In 1895 this work was in good condition and grass was growing between the bricks. On the River Po, near Crespino, the mantle has been used to protect a communal hospital which was in danger from the cutting away of the bank in a curve in the river. This mantle is about 800 ft. long, and it is said to extend under the water for about 130 ft. It has stood two years' wear without any injury and has stopped all erosion, though the bank is very steep. Its cost was about $1,500, including the preparation of the bank for the mantle.

Mr. Villa says that a single threading machine will keep 15 men busy and make 180 sq. yds. of mantle "per day," without specially trained men. As to cost, the inventor supplies the following estimate for one square meter, stating that one of the chief advantages of this system of bank protection is that the cost can be definitely fixed beforehand, at so much per square yard, regardless of the stage of water, etc.:

Cost per Square Metre in Francs.

17 cement bricks	3.40	francs.
2 bundles of wooden slats	.20	"
2.2 lbs. of galvanized iron wire	.35	"
Foreman	.50	"
Tools and labor	.15	"
Cost per square metre equals	4.60	"

This is equivalent to about 77 cts. per sq. yd., though the materials and labor are doubtless figured on a European basis in the above. Mr. Villa says that the use of terra-cotta bricks would reduce the above total to 3.75 francs per meter, or say to 63 cts. per sq. yd. The plant required for a considerable piece of work is estimated as costing $20,000 in Europe, and included in this plant are:

6 barges, at 5,000 francs each	30,000	francs.
6 hand machines for threading	18,000	"
Tools	5,000	"
Chains and rope	5,000	"
12 small boats	6,000	"
Office expenses, etc.	20,000	"
Contingencies	16,000	"
Total	100,000	"

The English patents seem to be controlled by the "Villa's Patent Mantle Syndicate, Ltd.," of Liverpool; the inventor is Signor Giovanni Villa, of Milan, Italy, and the present owner of his patents is Signor Riccardo Biragchi, of Milan.

◆

THE USE OF OLD RAILS AS UNDERGROUND CONDUCTORS.*

By F. O. Rusling.

While the writer was the Superintendent of the Buffalo (N. Y.) Railway Co., serious indications of electrolysis of the pipes within a half-mile of the power-house made it necessary to call in expert advice to put a stop to the trouble. A careful and thorough electrical survey was made of the entire district. This was a long and difficult matter, since there were three systems of natural gas pipes, two of illuminating gas, one of water and two conduit systems. Although the pipes were already connected to the negative bus-bar by large copper cables, it was found that these were entirely inadequate, and that there were two points where the pipes at heavy load were 3 to 5 volts positive to the adjacent rails. One of these points was 1,500 ft. north and the other 1,800 ft. east of the power-house.

The expert calculated that, until extensive changes could be made in rail returns, the former point would deliver about 1,000 amperes and the latter about 3,000. To bring this current to the dynamos with but 5 volts loss would need over $8,000 worth of copper. While hesitating over this large expenditure it occurred to us that there were about 300 tons of old tram rails on hand that might be used for the purpose. These were flat, center-bearing rails, originally weighing 56 lbs. to the yard, but worn down to 50 lbs. or less; they were high in carbon, hard and brittle.

---

*Reprinted from the "American Gas Light Journal."

The best scrap price obtainable was $8 per ton, delivered. Our expert carefully tested their conductivity with 1,000 to 1.500 amperes, using an instrument reading to .001 of a volt in order to secure accuracy. As the showing was satisfactory, it was determined to try the rails on the 1.500-ft. length, which would require four rails in parallel to give the desired results. A trench was dug between the curb and sidewalk and a continuous trough of rough lumber put into it.

The rails were bolted together in pairs back to back, and arranged so that the end of one rail was at the center of its mate. The bonding was effected by scraping contact spots with a file near the end of each rail and amalgamating them with the Edison solid alloy. A steel washer ¼-in. thick, 1⅛-in. inside diameter, and 4 ins. outside was dipped into hot insulating compound and placed against one rail so as to inclose the contact spot. The hole in the washer was filled with the Edison-Brown plastic alloy, inclosing an amalgamated steel spiral spring. The upper rail was then bolted on and the completed conductor lowered to the bottom of the trough, resting on one edge so that gravity would maintain the contacts. It will be evident that with this arrangement two of the bonds on any one rail would have to give way before the circuit could be broken; each bond was made large enough to transmit 1,500 amperes. When the second set of rails was lowered into place, the trough was filled with a hot insulating compound and a cover nailed on. This compound was cheaper and better than asphaltum; it remains viscous even in cold weather and has high insulating qualities. It is a product of petroleum distillation much lighter than asphaltum and costs about $25 a ton.

This four-rail conduit was connected up and carried at heavy load, 1,100 amperes, 1,500 ft. with a loss of but four volts. This result was so surprising that our expert suspected that his instruments were wrong and sent them back to Weston for recalibration; they were returned, but proved that the measurements were correct. To appreciate the performance of these old rails and their bonds I need only say that, to give the same result, it would require a copper section of 3.55 sq. ins.; 1,500 ft. of this would weigh 20,532 lbs., and cost at 12 cts. per lb., $2,462.83. Our four-rail lengths weighed 50 tons and cost as scrap but $400. The resistance of steel as compared with copper is usually considered to be between 7 to 1 and 9 to 1. but this including 50 bonds in each length, was about 5.63 to 1. The tests proved that the plastic bonds actually did make an "electrically continuous rail," and after a year's service they are still maintaining their conductivity. This is more than can be said of any copper bond ever used. It will be noted that steel like this, even at $30 per ton, would be cheaper than copper as a conductor.

As the steel was so hard and brittle, a great deal of time was required to file the contact spots and to bore holes for the bolts to hold them together, so another method was adopted in the second case. In the power-house is an air compressor for cleaning out armatures and removing dust from the boiler-house walls. An iron pipe was connected from the air reservoir to the yard and a single layer of rails, bottom up, was put on each wagon. Each load was carried into the yard and the contact spots were rapidly cleaned with a reciprocating pneumatic tool, borrowed from a boiler shop. To avoid drilling the rails, pieces of ¾-in. iron, about 24 ins. × 8 ins., were placed in the trough every 15 ft. These were bored at the ends for a pair of countersunk ¾-in. bolts and had four contact spots cleaned with an emery wheel. On these were laid the plastic bonds and four rails side by side, with base down. The spaces between the treads were just right for a second layer of three rails bottom side up. Then another set of bonds and an iron plate ¼-in. thick, 20 × 8 ins. On these more bonds, other layers of four and three rails, and finally a ¾ × 24 × 8-in. top, bolting all layers together. The sides of the trough were but ½-in. from the rails between clamps, so as to save wasting insulating compound, with wider spaces to accommodate the clamps. Rail joints were broken as before.

This construction allowed very rapid and satisfactory work compared with the first. The performance was also satisfactory, as the 14 rails transmitted 3,250 amperes 1,800 ft. with but four volts drop; an insulated pilot wire was put down with this conduit and permanently connected with a voltmeter in the power house. The rails used in this conduit weigh about 210 tons, which at $8 would amount to $1,680.

It would require a section of 12.48 sq. ins. of copper to equal in conductivity the section of 70 sq. ins. of steel. This copper would weigh 86,580 lbs., and at 12 cts. per lb. would cost $10,389. The total cost of the rails and bonds, for both conduits was about $3,322, as against $12,852 for equivalent copper. The labor to install the copper would of couse be less, but on the other hand we had the rails in stock and the only actual outlay was for labor, bonds, lumber, bolts and insulating material. I have not the details of these now at hand; my recollection is that the total expenditure did not exceed $2,500, and that we thus secured results which would otherwise have cost nearly $15,000.

From my experience with copper bonds I should not advise the use of buried rails for conduits if ordinary copper bonds are used for connections. Even when new it is impossible to get the full conductivity of the rail, and the contacts get worse and worse as time passes. The copper when covered with the damp earth will oxidize at a rate determined by the composition of the soil and the amount of current transmitted.

◆

A 54-IN. WOODEN BARREL SEWER.

By J. C. Meem, Assoc. M. Am. Soc. C. E.

The accompanying sketches show sections and details of a typical 54-in. wooden barrel sewer, adopted from plans of similar ones, recently designed and built in Brooklyn. Mr. Chas. H. Myers, M. Am. Soc. C. E., Engineer in Charge of Sewers, however, makes no claim to originality, as the Brooklyn plans are practically the same as those used by the Dock Department of New York.

The sketches show two designs, Fig. 1, with boxed supports for pier extension, discharging through a mouthpiece in the bottom; and Fig. 2, with supports better adapted for cribwork, and with an open end discharge. The general construction is similar in both cases, except when shown to be different in the plans.

The "streaks" or staves are creosoted with 10 lbs. of dead oil of tar, weighing 8½ lbs. per ft. at 120° F.

The intermediate bands and the cover bands for the joints are of galvanized iron, as is also the mouthpiece which is fitted to the opening in the sewer. This last is bolted to the staves at the four corners and to a galvanized iron strap which goes over the sewer at the center of the opening.

In constructing the sewer it is made in 20-ft. sections and floated to place at high water, or else it is set up in position, according to circumstances. A little calking may be given to the joints between sections when it is impracticable to get a good fit. The simplicity of their construction and the durability of these sewers make them especially desirable for this character of work.

The sewers are built in elliptical or other shapes as well as circular, according to necessity.

FIG. 2.—DETAILS OF PIER EXTENSION OR CRIBWORK

A 54-IN. WOODEN OUTLET SEWER AT BROOKLYN, N. Y.

THE FAIRMOUNT PARK ELECTRIC RAILWAY, at Philadelphia, Pa., is now completed and nearly ready for traffic. It opens up communication with all parts of the great park, and all roadways and drives are crossed below grade. The power-house has an engine room 156 × 55 ft., and a boiler room 156 × 36 ft., with a large coal storage vault. There are three tandem compound Corliss engines, each directly connected to a General Electric dynamo of 500-K-W. capacity. Steam is supplied by six Berry vertical boilers of 250 HP. The boilers and engines were built by Robert Wetherill & Co., of Chester, Pa. The car shed is 425 × 114 ft., of ornamental design. The equipment includes 30 motor cars and 30 trail cars, each seating 72 passengers. Each car is mounted on two four-wheel trucks, with 33-in. wheels, and each motor car has four motors. All the cars have electric brakes. They were built by the J. G. Brill Co., of Philadelphia, Pa.

◆

NEW STEEL MAKING PROCESSES claimed to supersede the Bessemer process, are invented every year or two, and achieve a brief notoriety through the medium of the daily papers. The latest is the Hawkins' process, which is described in three columns of fine print in the St. Louis "Globe-Democrat" of Oct. 25. As nearly as we can understand, the operation of the process is as follows: Pig iron melted in a cupola flows in a stream into a reverberatory furnace beneath; the stream is met by two jets, one of air and one of steam. The steam or hydrogen blast is supposed to turn sulphur into a gas that is burned up, and to turn the phosphorus into a slag which floats on top of the melted metal. The latter is then tapped out of the reverberatory furnace or "converter." Experiments are said to have been made with the process by Chicago capitalists at the old Jefferson Steel Works in Birmingham, Ala., in a plant which was erected at a cost of $10,000. A dispatch received from them says "Parties interested jubilant over results and declare it a revolution in steel making." The most absurd claims are made for the process, such as that steel may be made by it as cheap as cast iron, and that steel castings made from the Hawkins' process are equal to steel forgings.

◆

ALUMINUM CAN BE SOLDERED OR BROWNED, says Dr. Gottig, in the "Metallarbeiter," as follows: The aluminum is treated with a solution of ammonia alone, or with ammonia in the presence of salts of ammonia. In the first case, the aluminum, which always contains a little iron and silica, is dissolved on the surface; but the silica and the iron remain and form an adhering coating of a brownish yellow or a blue-grey color; the color varying with the amount of impurities in the metal. In the case of the treatment with ammonia in the presence of salts of ammonia the iron is also dissolved and the silica alone remains. But the combination formed reacts upon the ammoniacal salts and the deposit of hydrate of alumina and oxide of iron again forms a protecting coating. The physical and chemical properties of the surface of the aluminum are so modified that this surface will resist the action of humid air and waters slightly acid. Another advantage is that the aluminum thus treated can be easily soldered and electrolytic deposits will adhere strongly.

◆

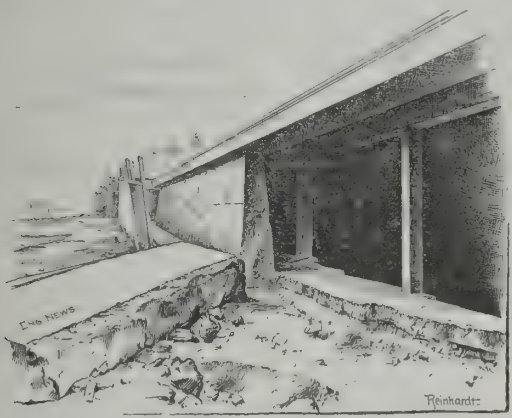
THE WESTERN UNION TELEGRAPH CO., according to its annual report for the year ending June 30, 1896, owns 826,929 miles of wire, has 21,725 offices, forwarded 58,760,444 messages, for which it received an average toll of 30.9 cts. at an average cost per message of 24 cts. In 1893 it transmitted nearly 66,600,000 messages and received 31.2 cts. for each at a cost of 22.7 cts. The gross earnings for the year 1896 were $22,612,736, with operating expenses of $16,714,756 and net earnings of $5,897,980. The company is reconstructing its trunk lines with copper wire, with excellent results.

A RESERVOIR FAILURE AT OAKLAND, CAL.

A reservoir on Vernon Heights, Oakland, Cal., belonging to the Oakland Water Co., failed about 6:30 a. m., Oct. 20. No damage was done beyond flooding basements of houses for a few blocks. The accompanying view was drawn from a photograph taken the next day.

The original reservoir was about 100 ft. square, partly in excavation, lined with brick, and plastered on the inner face with a coat of asphalt. It extended to the height of the ledge shown in the photograph.

To increase its capacity, a wall of asphalt concrete was built around the old reservoir, 8 ft. higher, and connected with the brick and asphalt lining by an 8-in. layer of the same material. This wall was 2 ft. wide at the base and 1 ft. at the top, with its inner face vertical. It had no depth in the ground and no footing, and was built partly on made earth. This upper wall failed. The break showed no bond between the wall and the horizontal layer, but it did show a break in the bond between the upper and lower parts of the wall (also shown by a crack in the wall left standing).



A Reservoir Failure at Oakland, Cal.

It is stated that previous to the break, water had been carried to within 1 ft. of the top of this wall and at the time of failure it was 22 ins. above the ledge.

The reason assigned by the water company for failure was the explosion of dynamite by some malicious person.

We are indebted to Mr. Geo. S. Dillman, of Dillman & Wallace, San Francisco, for the above information, and for the photograph from which the view was drawn.

NOTES FROM THE ENGINEERING SCHOOLS.

Lehigh University, South Bethlehem, Pa., opened Sept. 23, with a Freshman class of 115, as against 75 last year. The president announced the return of Professor Thornburg, the head of the Mathematical Department, who had been on leave of absence for the past year, and the addition of two new instructors in the departments of Mechanical and Electrical Engineering.

A characteristic feature of the technical instruction at Lehigh University, is the regular and systematic instruction given to the students in the shops of the Bethlehem Iron Company, and the shops of the Lehigh Valley R. R., at South Easton.

On Founder's Day, Sept. 8, Mr. John H. Converse, of Philadelphia, a member of the firm of the Baldwin Locomotive Works, made the annual address. Mr. Converse is a graduate of the University of Vermont, and much interested in educational matters. His address on "Citizenship and Technical Education," which will be published by the University, will attract much attention on the part of engineers and educators. He advocated a college course which should for the first three years be devoted to culture studies and the humanities, and for the last two or three years to professional subjects.

The "Combined Courses," at Lehigh University, which cover five or six years, and lead both to the degree of A. B. and an engineering degree, are largely in the line of Mr. Converse's proposition. The chief objection to the present system of education of engineers in our technical schools is its one-sidedness. If we are to make this education broader we must take more time for it.

Separate pamphlets are issued by the different engineering departments, describing in detail the methods of instruction. We have received three of these pamphlets, describing, respectively, the courses in civil, mining and mechanical engineering.

At the University of Michigan, Mr. John R. Allen, Univ. of Mich., '92, and J. T. Faig, Mich. & Agl. Coll., of Kentucky, '94, have been appointed Instructors in Mechanical Engineering, to fill the place vacated by the resignation of Asst. Prof. F. C. Wagner, who has gone to the Rose Polytechnic Institute, at Terre Haute, Ind.

At the Massachusetts Institute of Technology, the equipment of the engineering laboratories has been increased by the acquisition of new apparatus as follows:

In the laboratory of Applied Mechanics has been added a 100,000-lb. Olsen testing machine, capable of testing specimens 5 ft. long and under. In the same laboratory has been added a frame of two large iron girders, and other suitable apparatus, provided with a set of steel rods, which, with a pair of large cast-iron skewbacks already in the laboratory, make a machine of 400,000-lb. capacity for testing masonry arches of such sizes as are used in practice. To the Mechanical Engineering laboratory has been added a 36-HP. Otto gas engine, which is to be used mainly for purposes of investigation. An apparatus for testing steam injectors has been built and was in use during the latter part of last year. A compound Marsh pump of a capacity of 800 gallons per minute has been loaned to the laboratory for experimental purposes. In the Hydraulic laboratory has been added a calibrated measuring tank of 20,000 lbs. capacity, in addition to the old tank of the same capacity. Each is equipped with ten quick-opening valves, enabling large quantities of water to be measured accurately.

In the double number of the "Technology Quarterly," just issued, dated June-Sept., 1896, will be found Nos. IV. and V. of the "Results of tests made in the Engineering laboratories," No. IV. giving the detailed results of the test of the triple engine of the Chestnut Hill Pumping Station, made in May, 1895, by the students under the direction of Prof. E. F. Miller. No. V. contains the detailed results of tests made in the course of the regular work of the laboratory of Applied Mechanics, on the following subjects:

1. Tests on two series of bolted joints.
2. Tests on wrought-iron pipe of different sizes, used as columns.
3. Tests of spruce and of Norway pine beams.
4. An extensive series of tests of the compressive strength of timber at right angles to the grain.
5. Torsional tests of shafting, mostly 2 ins. in diameter.
6. Tensile tests of specimens or steel and of iron, of wire, of manila, of cotton, of hemp, and of sisal rope, and of the strength of alloys.

During the last school year, in the course of the regular laboratory work, complete tests of two large plants; one a 50-hour test of the West End R. R. Power Station, at Sullivan Square, Charlestown, and one a 24-hour duty test on the triple engine of the Chestnut Hill Pumping Station.

Extensive additions have recently been made to the plant of dynamo-electric machinery. The principal of these are a 30 arc-light Brush machine, a 30-HP. Westinghouse 4-pole direct current machine, and a 10-HP. Westinghouse direct-current machine, arranged so as also to give quarter-phase alternating currents when desired. This machine can also be used as either a direct or alternating current motor, or as a rotary transformer. Two 20-HP. transformers have been added to be used in connection with the large alternator already possessed by the Department. All of this apparatus is for regular use in the laboratory by the students.

There is also under way a new plant especially arranged for illustrating the testing of the combined efficiency of steam engine and dynamos. It consists of two similar multipolar direct-current dynamos, of 35-HP. each, made by the General Electric Co. These will be driven by a separate compound high-speed engine.

A 20-HP. electro-magnetic transformer for heavy currents has also been added to the equipment. This is intended to be used particularly for the study of the heating effects of very strong currents. There has likewise been constructed a transformer giving a pressure of 40,000 volts, whose special use is to determine the electrical strength of materials used for insulating purposes, A large addition has also been made to the storage-battery equipment already possessed by the department.

Many additions have been made to the apparatus for precise measurements in electricity and heat, including special forms of apparatus for studying the errors of standard thermometers, and for determining thermal conductivities. A new standard air condenser should also be mentioned.

The New Mexico College of Agriculture and Mechanic Arts, Mesilla Park, N. Mex., sends us a photograph of its new engineering building. It is a flat-roofed one-story building of a very substantial appearance, and differs in one particular from probably every other engineering college laboratory in the country in being built of adobe, plastered inside and out. The adobe bricks (unburned clay and straw) are laid up in thick walls, making a building cool in summer and warm in winter; and in a land of sunshine and little rain, they make a very durable structure.

The equipment just added has been selected from the Davis & Egan Co., Egan Co., Fulton Steam Boiler Works, Laidlaw, Dunn, Gordon Co., Springfield Emerywheel Co., Weston Engine Co., Standard Scale Co., and other makers. The college offers four regular courses, viz., Agricultural, irrigation engineering, mechanical engineering and scientific. Spanish is thoroughly taught in the college. It is the prevailing language in much of New Mexico, and in all of the country southward.

The dry atmosphere and mild climate of New Mexico are very beneficial to those subject to pulmonary troubles, and the college has been of great service to many students who were unable to pursue such work at the eastern and northern colleges where the climate is more severe.

The engineering work is in charge of Frank W. Brady, M. E. (from Purdue University, Lafayette, Ind.), with Mr. Chas. Mills, assistant.

In the engineering department of the University of Minnesota, prizes for original theses have recently been awarded to students as follows: First prize, $50 and gold medal, to Mr. C. P. Jones, Jr., for thesis entitled, "An Original Design for the Steel Frame of a Ten-Story Building;" second price, $30 and a gold medal, to Mr. C. E. Magnusson, for thesis entitled, "Specifications for an Electric Lighting Plant for the Gillette-Herzog Mfg. Co." This system of prize-giving was instituted five years ago by the Gillette-Herzog Mfg. Co., of Minneapolis, Minn., with a view to stimulating original research in various lines of engineering. Their plan is to offer prizes as described above, placing the papers prepared by students in the hands of a committee composed of prominent engineers.

The Worcester Polytechnic Institute, Worcester, Mass., has made many important changes during the past two years. We are indebted to Prof. Sidney A. Reeve for the following account of them:

> News from this Institute can hardly be fully understood without a word as to the general changes which Dr. T. C. Mendenhall inaugurated upon his accession to the presidency and which are only now, some two years later, beginning to be manifest in works. Up to that time the Institute had remained one of the best schools for the training of mechanics which the country afforded. The growth away from this original character has, of course, always been responsive to the changing demands of the changing times; but within a few years this has been accentuated, and the school, still retaining its full original equipment of commercially operated shops, can boast a similarly complete equipment for scientific and technical education.
>
> The Washburn Shops continue to be the centre of the Institute. About them have sprung up in a very few years an array of laboratories, each specially equipped for its work. In chemistry, the special branches of gas-analysis, metallurgy, sanitary and industrial chemistry each have special laboratories, and, with the exception of the first, special professors devoted to them. The department of sanitary chemistry derives special advantages from Worcester's possession of the fine Blackstone River sewage-disposal works, which annually attract a number of experts in that line from all parts of the world.
>
> Applied electricity and electrical engineering now have

new laboratories of their own, with a new chair, occupied by Prof. Harold B. Smith. The lighter electrical work is carried on in the original laboratory, now remodelled; the heavier electrical power work occupies its portion of the new Power Laboratory, of which more will be said later.

The departments of pure mathematics and language have each been enlarged to meet the requirements of incrasing classes, and the superintendency of the Washburn Shops has passed into new hands. The most marked advance has been made in the departments of Mechanics and Steam Engineering. As the laboratories devoted to this work are of recent construction and of somewhat novel arrangement, a somewhat detailed description may be of interest.

The Mechanical Department.

The apparatus and work in this line was transferred about a year since to two new buildings erected especially for it from funds coming from the State of Massachusetts. One of these, locally known as the "Power Laboratory," is devoted to the study of questions in steam, electrical, and gas power, all on a commercial scale. The other, known as the "Mechanical Laboratory," is occupied by laboratories for lighter mechanical investigation into problems in general applied mechanics, strength of materials, hydraulics, kinematics and thermodynamics; it also contains an instrument-room, recitation and lecture rooms, and the mechanical and freehand drawing rooms.

The Power Laboratory contains two vertical 80 HP. boilers built for a steam pressure of 200 lbs., three horizontal steam engines, a condenser, absorption dynamometer, and the heavier electrical machinery. In the future it will also be equipped with a 100-HP. gas engine and power gas generator.

The possibilities in the line of combination of this apparatus, by means of clutches, quills, and a countershaft, are almost innumerable. The three engines, whose cylinder-volumes bear the ratio of 1 : 3.06 : 7.84, may be combined into a compound engine by the connection of any two of them, or all three may be run as a triple compound. The speed of any one or all, although all possess automatic cut-offs, may be varied so as to vary these cylinder-ratios to any value between 2 and 10. Any one or any set may exhaust into the atmosphere or into the condenser. Any one or set may be operated with or without steam-jackets, on barrel or on either head, and the jacket-water weighed separately. Between each pair of engines is a live-steam re-heater which may be used or not, and its condensation measured. While any engine or pair is being used experimentally, the other may be used to drive the commercially operated Washburn Shops, which normally consume about 25 HP., and which are driven from the Power Laboratory the year around. Finally, the power from any engine or any set may be carried over to the absorption-dynamometer and there weighed, or may be further transmitted up to any one of the three electrical generators for consumption or measurement.* The near future will add to this array of prime movers an 80 HP. motor receiving current from the Institute's Hydraulic Power Laboratory at Chaffinsville, five miles north of the city, and which may be similarly coupled in with the other apparatus in almost any combination. This hydraulic power laboratory, containing an 80 HP. turbine using the drainage from a 2,500-acre watershed under a 30-foot fall, with Venturi meter, absorption dynamometer, 10-ft. weir, and all accessory apparatus, constitutes practically a department of itself.

The circulating-water from the power-laboratory condenser is carried back to the Mechanical Laboratory building, where the laboratory hydraulic apparatus admits of its being measured by orifice, by weir, or by weight, or by all three in series. The same hydraulic apparatus of course is prepared for all experimental work in hydraulics itself, for which purpose water is supplied from a pressure-tank in the laboratory, for all heads up to 200 lbs. per sq. in. The tank is now being equipped with a mercury-column 33 ft. in height for standard orifice work, but which will also be used for testing gages or any other incidental work of the sort.

On the same floor are the testing machines: a 100,000-lb. Emery, a 50,000-lb. Fairbanks vertical, a Riehle torsion, and a Riehle light tension for wire and cement; to these is being added a 20,000-lb. Wicksteed lever-machine. The first of these machines is operated by water-power from the pressure-tank, under a system which permits the most delicate gradation of load and the retention of the load at any point almost independently of leakage. The others are operated by hand-power or belt-power.

Amongst the interesting work recently done by this section of the laboratory was the destruction by crushing of sixteen specimens of concrete of different compositions for a prominent firm of contractors and builders. The specimens were bedded in a mortar of plaster-of-paris, which was allowed to set while the specimen was under a strain of a few hundred pounds. The method of giving way to the strain which all of the specimens except three exhibited—that is, the leaving on the heads of the machine a pair of cones of material almost uninjured—gave rise to doubts as to whether the results were not more favorable to the concrete than would be the case in actual practice. It is perhaps, however, the only method of reducing the test-results of different mixtures and machines to a just basis for comparison. The following table gives the results of the compression tests of concrete cylinders, Sept. 28 to Oct. 1, 1896, axial compression:

	—Dimensions.—				—Strain—Lbs.—		
Mark.	Length, inches.	Cross-section, sq. ins.	Weight, lbs.	oz.	First crack.	Ultimate.	Per sq. in.
AT 1	8.15	28.22	18	12	25,000	26,900	954
AL 1	8.10	28.32	18	14	18,200	22,700	802
D 1	8.05	28.22	..	..	22,500	22,500	800
G 1	8.08	28.20	18	12	28,000	28,900	1,025
S 1	8.11	28.32	18	11½	20,400	27,200	961
R 1	8.08	28.22	17	7½	3,000	6,200	220
AT 2	8.11	28.04	..	..	89,900	89,900	3,210
S 2	7.97	28.13	17	11½	89,600	89,600	3,190
AT 3	8.12	27.94	..	..	19,000	35,800	1,280
S 3	8.06	28.32	18	9½	51,200	51,200	1,810
AT 4	7.98	28.13	18	9	25,500	28,500	1,013
S 4	8.06	28.41	18	7½	33,800	34,800	1,225
AT 5	12.12	50.68	52	11	Strained to 100,000 lbs. without apparent injury.		
S 5	12.13	50.36	50	15	64,400	69,100	1,371
D 5	12.17	51.06	50	11	81,400	82,200	1,609
G 5	12.11	50.30	52	2	99,100	100,000	1,988

NOTES.—The mixtures had set about 30 days, the exact time being unknown in the laboratory.

AT 3 was not well filled out on one side with sand and cement—irregular, elongated cavity about ½ in. wide and deep.

S 3 was full of small cavities on outside.

G 5 was not well filled out on a complete circle about 1½ in. from one end; but specimen did not give way there.

The mixtures were in proportions indicated by the numbers as below, the stone of No. 2 being fine stone of 1½ in. mesh.

No.	Stone.	Sand.	Cement.
1	5	2	1
2	2	1	3
3	4	2	1
4	6	3	1
5	4	2	1

The letters indicate different brands of cement.

Some recent tests of interest were made upon steel strips cut from a rifle-barrel which had been in actual use.

A recent acquisition in this connection has been an optical extensometer which reads, and with accuracy, verified within the limits of probability, to $\frac{1}{20{,}000}$ in. in 8 ins.

This same laboratory contains, besides the hydraulic apparatus already mentioned, a special small surface-condenser and three experimental steam-engines for thermo-dynamical problems. It is expected that a refrigerating and ice-making machine, erected solely for experimental and illustrative purposes in thermodynamics, will be shortly installed.

The department of drawing, which occupies the top floor of this same building, has recently received a new head, Prof. Ames, who is remodelling the course so as to unify all the branches—free-hand, mechanical drawing, and machine design—and all the four years' work, so as to lead towards a complete and homogeneous education in that direction.

In the electrical engineering department a post-graduate course has been established, which includes 14 hours per week of laboratory work, and 12 hours of electrical engineering design, besides lectures, reviews of current electrical literature, etc. The following new electrical machines are being placed in the Power Laboratory: A 30 K-W. 110-volt compound direct current dynamo, and one of 60 K-W. 500 volts; a 30 K-W. 1,000-volt single phase constant potential alternator, and a 60 K. W. 3,000-volt 3-phase motor to take current from a generator located at the hydraulic power plant of the Institute at Chaffinsville.

The Colorado State School of Mines is about to apply to the coming session of the legislature for an extension of space, the applications for admission having overrun the capacity of the present buildings. The summary of attendance shows that 33 per cent of the students are from outside of Colorado.

DERAIL FOR THE GIBBS ELECTRIC STREET RAILWAY INTERLOCKING DEVICE.

The greatly enlarged liability to serious grade-crossing accidents, which has followed the rapid increase of high-speed electric railways, has become so evident by frequent collisions and still more frequent narrow escapes that the need for a suitable protection for such crossings is now seldom questioned. It is also quite generally recognized, in the most advanced practice, that the old highway crossing gate is inadequate to the conditions of heavy, high-speed electric cars not infrequently rendered uncontrollable by the blowing of a fuse or jumping of the trolley, and that the logical solution of the problem is along the lines of the mechanical interlocking signals used at steam railway grade crossings. In our issue of Feb. 22, 1894, a special interlocking plant of this character, invented by Mr. Geo. Gibbs, M. Am. Soc. M. E., Mechanical Engineer of the Chicago, Milwaukee & St. Paul Ry., was described in some detail, and since that time the device has come into quite extended use along the lines of that company and on other railways.

The particular characteristics of Mr. Gibbs' device, as will be remembered, are: (1) the motive power of the electric cars is cut off when it is necessary to block the line; (2) a derailing device is provided to prevent the cars from drifting over the crossing. This derail resembled the scotch block sometimes used with steam railway interlocking apparatus rather than the derailing switch proper, and has recently been supplanted by Mr. Gibbs with a device more nearly approaching the ordinary derail. Through the courtesy of the inventor we are enabled to present herewith details of this improvement.

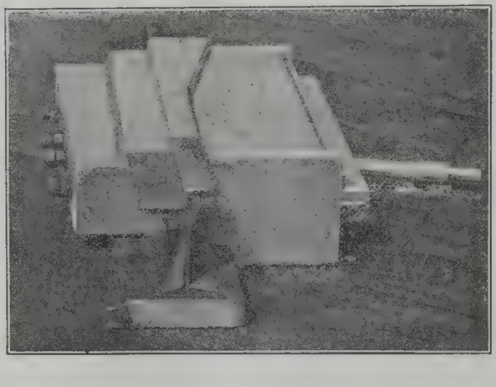

Fig 1.—Derail Closed.

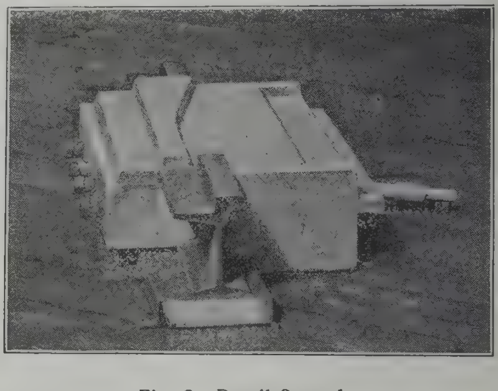

Fig. 2.—Derail Opened.

VIEW OF DERAIL FOR GIBBS' ELECTRIC STREET RAILWAY INTERLOCKING SYSTEM.

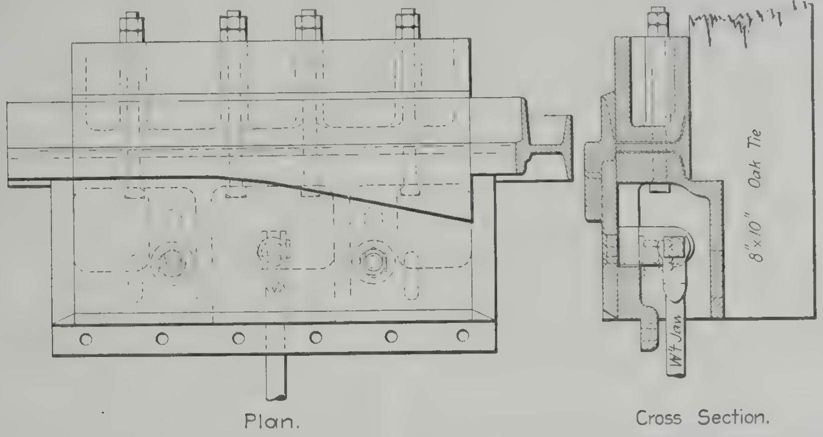
A brief consideration of the structure of the ordinary derailing switch will show its inapplicability to street railway tracks. It breaks the continuity of the rail, weakens the track, and affords an opportunity for destructive battering which can only be prevented by assiduous attention in keeping the joints tight and the ties well surfaced and tamped. In street railways the position of the ties and rails below the pavement renders impracticable this attention, and further the construction is an obstruction to wagon traffic, and is especially liable to clogging by mud and ice. The attempt was made to overcome all these difficulties in the derail illustrated. As will be seen by the illustrations it consists of two cast-iron boxes, bolted to each side of the rail through the web, and a cast-steel plate sliding on these blocks through a passage provided by cutting out the rail head for a distance of 26 ins. Cast on the top of the sliding plate is a suitable projection or ridge to replace the rail head cut away, when the derail is closed, as shown by Fig. 1. Fig. 2 shows the derail in the open position, that is thrown to one side, so as to break the track and derail the car. It should be noted here that the apparently narrow flangeway is due to the fact that when the photograph was taken the sliding plate had not been fully thrown open. In Fig. 3 the details of the various parts of the derail are clearly shown and need not be described further.

---

*Some preliminary tests of these engines will illustrate this opportunity of varied combination. While the middle engine of the three was driving the Washburn Shops upon 60 lbs. non-condensing, the first and third were running condensing under 110 lbs. of steam under a brake and indicated efficiency test. The water consumed was 15¾ lbs. per I. HP. per hour. After the test the shops were transferred from one engine to another without any interruption whatever.

The features to be noticed particularly in this device are: (1) The web and flange of the rail are left intact, only the head being cut away; (2) the device is applied to the rail by bolting through the web, and consists of two cast-iron boxes which have footings on the same crossties which carry the rail. Owing to this fact it is not necessary to make a special foundation for the derail or in any way to disturb the ties and their bedding; (3) a smooth surface is presented at a level with the street paving for the passage of wagon traffic; (4) the sliding plate has beveled edges to make it self-cleaning from mud or snow and ice; (5) all operating parts are protected from injury; (6) the operating rod or pipe is attached about 4 ins. only under the surface of the street, by which difficulty from drainage in deep boxes is avoided.

A number of derails of this construction have been put into use, the latest having been recently installed at Indiana St., Chicago, Ill., in a plant built by the National Switch & Signal Co. All of these have worked satisfactorily, being easily operated by the levers and infallibly derailing the cars as has been demonstrated on several occasions. It is stated that in passing over this derail no perceptible jar is felt, indicating that there is no deflection of the track by reason of the cutting away of the head of the rail.



Plan. Cross Section.

FIG. 3.—DETAILS OF DERAIL FOR GIBBS' ELECTRIC STREET RAILWAY INTERLOCKING SYSTEM.

RAILWAY TERMINAL STATIONS.*

The passenger movement at terminal stations is composed of three classes: 1, Through or long distance; 2, suburban or short distance; and, 3, excursion or irregular travel. In addition to these three classes of travel, it is generally necessary to provide for express and mail matter, and in many cases for the handling of milk.

The long distance passengers have a large amount of baggage, some of which can be taken directly to or from the train, but a large proportion requires provision for storage, and all requires provision for handling while at the station. Passengers of this class usually upon arrival go to their destination by some conveyance, either carriage or street car, so that the location of the station is of less importance to them than to those of the second class. Its arrangement as to comfort of waiting rooms and convenience of baggage rooms is of greater importance. Many passengers of this class wish to take the cars of some railway other than those of the road upon which they arrive. If the trains of both railways are in the same station, with convenient provision for the prompt transfer of the passengers and their baggage from one to the other, their comfort and convenience are served in the best manner. This result is reached in many of the union stations which have become common within the last few years.

The second class of traffic, including the greatest proportion of passengers using the terminal station, including all passengers whose work calls them to the city daily, have very different requirements. They do not need such provision for baggage nor waiting rooms. They reach the station just before the time of departure of their trains and hurry from their trains immediately on arrival. Inside the station, convenient ways for quick ingress and egress are the primary requirements, with a good system of running and despatching trains, and conspicuous and plain indicators showing destination and starting time of trains. To this class, the location of the station is of great importance, and for it, on general principles, the station should be as near the business centre as possible. If this class of business is to be attracted to the railway, the facilities offered and cost of transportation must be as favorable as those of competing lines. The majority of this class are people with small incomes, to whom the addition of a street car fare daily to the steam car fare is a serious expense, hence the necessity of bringing them as near to their places of business in the city as possible.

For the third class noted above, the location of the terminal station does not play so important a part, neither does the arrangement of waiting rooms and baggage rooms. The main features needed are large space and free egress from the trains for the excursion crowds. Care is needed also to have the train indicators plain and conspicuous, and proper provision for preventing crowds from going to the wrong train.

At first the steam railways took the larger share of suburban traffic. As the territory along their lines within reasonable distance of the city became built over, it became necessary to develop the territory between them. This was at first done by omnibuses and horse cars. It has become necessary to build farther from the business centers and farther from the suburban stations of the steam railways. The heavy passenger traffic brought about by the latter movement and the absence of branch feeders to the steam railways, has enabled the electric railways to develop and extend the street systems formerly operated with horses, and, by the superior facilities offered, to bring such competition as to seriously affect the earnings of the suburban steam lines. To meet this competition successfully, the steam railways must have better facilities than were called for by the small traffic of former times.

It may be interesting to show the number of passengers carried by the railways entering Boston during 1894:

	Total.	To and from Boston.
Boston & Albany..	12,152,000	7,546,000
N. Y., N. H. & H....	44,448,000	13,831,000
New England....	8,146,000	3,426,000
Boston & Maine....	33,385,000	21,654,000
Fitchburg....	7,117,000	4,055,000

Arranging these figures in groups according to the railways which use the north station and those which will use the new south station, the distribution is as follows:

	Total.	To and from Boston.	Trains per day.
North station.. ..	40,448,000	25,709,000	574
South station	64,502,000	24,803,000	678

After the location of a terminal station has been determined, the point next in importance is the arrangement of the buildings and tracks. The headhouse usually contains the waiting rooms for passengers, with ticket offices, toilet rooms and lavatories for men and women, news stands, restaurants, telegraph and telephone offices and information offices. It is also necessary to provide for baggage and express rooms, and often a place for the milk traffic. Besides the above noted rooms pertaining directly to the passenger traffic, provision must be made for many things incident to such traffic, such as rooms for trainmen, sleeping car companies and station officials, store rooms and other rooms for uses connected with the passenger business, but not used directly by the passengers.

In general, the station should be so designed that baggage, express goods and milk, with such other articles as may be received or delivered at the station, shall be handled either below or above the level of the tracks, and in most cases it must be below such level. There are several reasons why such an arrangement is desirable. The movement of passengers and of trucks conveying baggage on different levels makes it safer and easier for people to make such movements as are necessary or desirable about the station. The risk of injury to passengers is much reduced, and less platform room is required for the same amount of business. The movement of both passengers and goods can be made promptly.

On the score of economy of space and cost of land, it is better to have all work pertaining to baggage and freight under the headhouse and trainshed below the level of the tracks, thus making two uses of the ground area, which is quite an important saving where land has such value as is generally the case near the business centers of cities. Such an arrangement renders it possible also to give more and better space to carriages and teams receiving and delivering baggage and goods, also to separate the receiving and delivering points for the various classes of traffic in the station.

With the tracks above the level of the surrounding streets, passages can be made from the tracks to the streets by the most direct course, enabling passengers arriving on trains to disperse much more easily and quickly than if they are obliged to all pass along the platform and out through the headhouse. At times of extraordinary movement of passengers, this is quite an important element in their safe and prompt movement. Objection is sometimes made to such an arrangement, that it renders it necessary for passengers to go up or down stairs and that elevators are needed for the use of passengers. With careful planning, however, inclined ways can generally be provided which can be used by such passengers as object to climbing stairs.

Placing the tracks at a higher level admits of crossing above the streets near the station, avoiding the necessity of crossings at grade or of expensive changes of streets, which in important cities carry with them not only the great direct expense of making the changes, but also a greater indirect expense in the detrimental effect on the value of property. It is also generally possible to obtain better architectural effects with the tracks above the street level, as is well shown in many of the stations recently built in London and various German cities and notably in the terminal stations in Philadelphia.

Generally at terminal stations, space is allowed for carriages and cabs to stand while waiting for inward trains. In many English stations, a wide space between platforms at which long-distance trains arrive is devoted to this use, so that passengers leaving the cars can go directly across the platform into the cab. A practical objection to providing room for carriages under cover is that it is impossible to keep such places clean and free from odor.

In designing a trainshed, if the cost can be ignored, a roof of large clear span is desirable, but with most railways it is necessary to consider the first cost, and as short spans with rows of posts between the tracks give the greatest economy in construction, this plan has been followed in many of the trainsheds recently built. With the improvements in the manufacture of glass, it has become possible to make a large portion of the roof covering transparent, thus giving good light to the interior of the trainshed. The greatest objection to the use of short spans with posts is the trouble experienced in taking care of snow and the difficulty of keeping the roof tight.

Platforms between tracks should be of some hard material which can be easily kept clean. The surface of platforms should be on the same level as the top of rails, so that baggage trucks and other wheeled vehicles can pass from one platform to another upon the same level, thus doing away with the need of moving such vehicles on the same platform with passengers taking or leaving trains. This construction is also safer for passengers, especially for those who get on or off moving trains.

Unless there is some very serious practical objection, inward long-distance trains should always enter on one side of the trainshed, and outward long-distance trains depart from the other side, although such an arrangement may cause more crossing of trains on tracks outside the trainshed. The middle tracks, those between the inward and outward tracks devoted to long-distance trains, should be used for short-distance suburban trains. These suburban trains can enter the station, discharge the inward passengers and take on outward passengers without switching, another engine backing onto the train and hauling it out, relieving the engine which brought the train in. This engine can follow the train out, going to some place where provision has been made for turning and taking water ready for the next trip.

The tracks in trainsheds are usually arranged in pairs, with a platform between each pair of tracks. For suburban trains it might be well in some places to lay three tracks together, in order to allow the locomotives to pass around the trains and avoiding the necessity of drawing the train out of the station before loading it for its outward trip. For tracks on which inward trains having a large amount of baggage and express goods arrive, it might be well to change the above arrangement by placing a narrow platform between the tracks of a pair, and using this platform for baggage and express trucks, thus keeping the regular platform free for the movement of passengers, avoiding what in many stations is a serious inconvenience.

---

*Abstract of a paper read by Mr. E. K. Turner, M. Am. Soc. C. E., at a meeting of the New England Association of Railroad Superintendents, at the United States Hotel, Boston, Mass., Oct. 12.

The modern application of interlocking switches and signals, with the improved methods of handling both switches and signals, together with the good track appliances and material now obtainable, makes it possible to do many things safely and promptly with moving trains that would a few years ago have been impossible, so that the crossing of trains from one track to another is now admissible, removing the principal objection to the arrangement of trains alone recommended. It is possible to have a terminal station too large, for anything beyond the room required for active use is not only wasted, but is positively objectionable. It increases the distance of those parts of the station between which passengers and employees must pass; it furnishes room for standing cars which should be stored elsewhere, and it leads to carelessness and lack of neatness in the care and policing of the station. Therefore, while a proper provision for growth of business should be made, care should be used not to carry this to an extreme.

BOOK REVIEWS.

A MANUAL OF STEAM BOILERS.—Their Design, Construction and Operation. For Technical Schools and Engineers. By. R. H. Thurston, M. A., LL. D., Dr. Eng., Director of Sibley College, Cornell University. Fifth edition, revised and enlarged. New York: John Wiley & Sons. 1896. 8vo.; pp. 881; $5.

This well-known work has now reached its fifth edition. It has been brought up to date by the addition of a good deal of new matter, among which we notice condensed reports of the tests on steam boilers recently made in England by Messrs. Donkin & Kennedy.

LOCOMOTIVE MECHANISM AND ENGINEERING.—With an Appendix on the Modern Electric Locomotive. By H. C. Reagan, Jr., Locomotive Engineer. Second Edition. New York: John Wiley & Sons. Cloth; 8vo.; pp. 419; illustrated. $2.

The first edition of this book was reviewed in our issue of April 19, 1894, and the principal addition to the second edition is the appendix on electric locomotives, which occupies nearly 100 pages. The book deals largely with the handling and emergency repairing of locomotives, while nearly 100 pages are devoted to modern types of American compound locomotives, and 80 pages to matters connected with the brakes. In the appendix the general operation of electric motors is described at some length, and particulars are given of the construction of the Baltimore & Ohio R. R., Sprague and Heilmann (French) electric locomotives. The book is written in a style easily comprehended, is well printed in large clear type, and is fully illustrated.

EXPERIMENTS UPON THE CONTRACTION OF THE LIQUID VEIN Issuing from an Orifice and upon the Distribution of the Velocities within it. By H. Bazin, Inspecteur Generale des Ponts et Chaussees. Translated by John C. Trautwine, Jr., Civil Engineer. New York: John Wiley & Sons. 8vo.; pp. 64; with diagrams. $2.00.

The author is already well known to engineers by his studies of the flow of water in open channels, made in connection with M. Darcy, and by his careful determination of the coefficients of discharge under widely varying conditions. In the present work, admirably translated by Mr. Trautwine, M. Bazin deals with the contraction of the liquid vein and the velocities within it, as observed in passing through rectangular and circular orifices in both vertical and horizontal walls. He treats of the method of determining the coefficient of discharge, the geometrical figure and transverse section of the vein, and, by a modified form of the Pitot tube, he ascertains the velocities in the vein and the distribution of these velocities. In his resume he says that his experiments do not show the generally-admitted existence of a contracted vein, if that expression is taken in the sense of a minimum section. In reality the vein, after being rapidly contracted upon passing the orifice, always continues to contract, much more slowly but constantly, as its distance from the orifice increases. While there is no doubt as to the absence of the minimum of section for veins issuing from circular and rectangular orifices there may be some doubt as to the square orifice, experimented with. In the distribution of the velocities in the plane of the orifice there is a minimum; in circular orifices in a horizontal plane this minimum is, of course, in the center and in vertical orifices it is a little above the center of gravity of the section. In the case of circular horizontal orifices the velocities are rapidly equalized as the distance from the plane of the orifice increases, and they soon become uniform through the entire transverse section. But this is not the case with orifices in a vertical plane; the minimum existing in the central region soon disappears, but the velocities in the lower part of the vein remain greater than those in the upper part. M. Bazin presents full data for all his conclusions, and gives in tabular form a long series of experiments in the determination of the velocities and of the pressures in the interior of the liquid veins.

DIE SCHWINGUNGEN EINES TRAEGERS MIT BEWEGTER LAST. (The vibrations of a girder under a moving load.)—By Dr. H. Zimmermann, Geheimer Ober-Baurath. Pp. 46; illustrations in text; 4 lithographed plates; paper; 8vo. W. Ernst & Sohn, Berlin. 1896. Price, M. 6.00 ($1.50).

In the calculation of the strains in a girder, due to static load, it is generally assumed that the live load in its various positions rests upon the girder; the fact is, however, that the live load often traverses the girder or truss with considerable speed.

The girder changes its outline under the passing live load; the latter, therefore, does not move in a straight line, but describes a curve. The movement of a body in a curved line is influenced by a centrifugal force, which depends upon the mass and the speed of the moving load. The pressure which the load exerts upon the girder is therefore dependent upon the bending moment of the latter and the speed of the passing live load; this pressure then causes the bending of the girder and incidental curvature of the line traversed. Intricate, as the law of the mutual dependence of these two factors may appear, it will still admit of mathematical investigation. Attempts in this direction have so far, however, utterly failed, as the error generally committed was to confound the curved line traversed by the moving load with the elastic curve of the girder. The author has attempted to treat this difficult subject from a mathematical standpoint. The method of integration employed here will yet admit of a solution, when the force acting upon the moving load is not unchangeable, but is a function of the position of the load. It need hardly be said that this is a piece of hair-splitting which will scarcely be applied in practical bridge design. It is an excellent example of the "mathematical engineering" which has caused so many practical men to look with distrust upon the work of technical schools. It is, however, a perfectly proper field for the student of pure mathematics, and there is no reason why it should be confounded with practical engineering studies.

A PRIMER OF THE CALCULUS.—By E. Sherman Gould, M. Am. Soc. C. E. Van Nostrand's Science Series No. 112. New York: D. Van Nostrand Co. 16mo., boards; pp. 91; with 17 folded plates. 50 cts.

The object of this little book is well expressed in the following words from the preface:

> This work is a development of the infinitesimal calculus as far as the first differentials of algebraic functions of one independent variable and their corresponding integrals. That is to say, it is restricted to the absolute rudiments of the science. Within these narrow limits, however, the treatment is tolerably full, and suffices to show how far-reaching a mathematical instrument the calculus is, even in its elementary steps. This seems to the author to be the best way of communicating a working knowledge of the science; namely, to teach a few elementary rules and then put them into immediate use, as far as they will go. The student then recognizes the necessity of the more advanced steps.

The ideas of the author, as expressed in the above extract, appear to be most excellent, and his methods of carrying them out in the book are admirable. He seems to have written the book with the intention of furnishing an easy introduction into calculus to the beginner of the study, and of making it interesting from the start by giving numerous practical examples of its application. We think, however, that the book may also be found useful to another large class of students, namely, those college graduates who toiled through calculus during their course with the object of passing an examination in it, and then proceeded as rapidly as possible to forget all about it. To many such students there comes a time in after years when they wish they could remember something of the subject, and to them this book may be useful as a refresher of their memories; in fact, it may offer to them a new view of a science which may thereafter prove to them a useful tool. The time at the disposal of the present reviewer will not allow of any critical examination of a mathematical work like this, but a rather hasty reading of the text shows it to be generally quite clear and accurate. Exception, however, must be taken to a couple of sentences on p. 29. The first is:

> The province of the calculus is to deal with ratios, which while constant as between the variables, are constantly changing as to their numerical values.

The meaning of the words "constant as between the variables," is not very clear, and the author in attempting to explain the sentence gives the differentiation of the equation of the parabola and then says the differential coefficient $dy \div dx$ "is the constant ratio of the infinitesimal increase of the ordinate to the infinitesimal increase of the abscissa, but it is changing its numerical value by infinite gradations." As the ratio $dy \div dx$ in the parabola has a different numerical value for every value of x, we cannot see how in any sense it can be considered a "constant." For the word "constant" the word "finite" should apparently be substituted, and the word "infinite" is, apparently, a misprint for "infinitesimal."

THE MANUFACTURE AND PROPERTIES OF STRUCTURAL STEEL.—By Harry Huse Campbell, S. B. New York and London: The Scientific Publishing Co.; 8vo.; pp. 397. $4.

Mr. Campbell is the superintendent of the Pennsylvania Steel Co., at Steelton, Pa., having been connected with that company since 1879, shortly after his graduation from the Massachusetts Institute of Technology. During the last few years he has contributed several papers on the subject of steel to the Transactions of the American societies of mining and civil engineers, which have shown an unusual amount of scientific study and experiment for one practically engaged in manufacture. The volume he has now produced is filled with matter of great value to every student of the subject of steel, and especially to the engineer who uses steel in construction. Mr. Campbell is not a professional writer of books, and the reviewer from a literary standpoint might find much in it to criticise. For instance he writes as if all his readers were well-versed in steel technology, whereas many of them will be young students who would like to have his definitions more clearly explained. Thus under the head of the Acid-Bessemer Process, he states that the operation is conducted in an "acid-lined vessel." This may be perfectly clear to those familiar with the difference between the "acid" and the "basic" processes, but it might be well to explain that the "acid lining" is made of fire-brick or ganister high in silica, while the "basic" lining is one high in lime and magnesia. Such literary defects, however, are of trifling importance as compared with the value of the work as a whole. Mr. Campbell is an original investigator, he has a great deal of valuable information to give as the results of his researches, and he gives it in his own way. We should be grateful to him for having thus given us the results of his labors, and not be hypercritical as to its literary form.

We are glad to observe that Mr. Campbell takes strong ground in regard to the retention of existing trade nomenclature. Thus he closes a discussion in which he unsparingly castigates those writers who have endeavored to thrust into our language the terms "weld-iron, ingot-steel," etc., by the following:

> By the term wrought iron is meant the product of the puddle furnace or the sinking fire. By the term steel is meant the product of the cementation process, or the malleable compounds of iron made in the crucible, the converter or the open-hearth furnace. This nomenclature is not founded on the resolutions of committees or of societies. It is the natural outgrowth of business and of fact, and has been made mandatory by the highest of all statutes—the law of common sense. It is the universal system among engineers not only in America but in England and in France. In other lands the authority of famous names, backed by conservatism and governmental prerogative, has fixed for the present, in metallurgical literature, a list of terms which I have tried to show is not only deficient, but fundamentally false.

In regard to the recent controversy concerning the elastic limit and the "yield point," Mr. Campbell takes equally strong ground, quoting from the editorial review of the subject in Engineering News of July 25, 1895, and approving the position there taken in the following words:

> These conclusions represent common sense in their summary dealing with the petty theories of enthusiasts, who are so wrapped up in the accurate determination of a micrometrical measurement that they ignore the more important variations inherent in the method itself, not to mention the still more overwhelming differences caused by changes in the history and shape of the material.

The first chapter of the book is entitled "The Errancy of Scientific Records," and is devoted especially to a discussion of the differences in results of chemical analysis of steel as obtained by different chemists. Then follow chapters on pig iron, on wrought iron, and on the several metallurgical processes by which steel is made. This portion of the book, which occupies about a quarter of the whole, will be of interest chiefly to metallurgical students. The remainder of the work appeals more directly to the structural engineer. It contains chapters on homogeneity and segregation, influence of hot working, annealing, the history and shape of the test piece, the influence of certain elements on the physical properties of steel, classification of structural steel, welding, steel castings and inspection. A great deal of space is given to a mathematical investigation by the method of brace squares, of the problem what is the influence of carbon, phosphorus, manganese, copper, sulphur and silicon upon ultimate tensile strength. To solve this problem, the records of 1,880 test pieces were taken, combined into 137 groups, and the average chemical analysis of each group was obtained. An enormous amount of mathematical work was performed upon this mass of data, resulting in the conclusion that the method of least squares is inapplicable to the problem if all the data are included. Thus the mathematical solution gave the absurd conclusion that .06% of sulphur would increase the strength of steel 22,000 lbs. per sq. in., when in fact it would cause only a very slight increase, if any. By neglecting the factors silicon, copper and sulphur from the mathematical equation and applying the method of least squares to the remaining factors, equations were reached which gives results which are probably as close to actual test records as any formula for relation of strength to chemical analysis can possibly give, although individual tests will frequently show wide differences from the result given by the formula.

The chapter on inspection should be carefully read by every one who has occasion to draw specifications for steel contracts. Dishonesty of manufacturers is a "sad fact" to which Mr. Campbell calls attention, and his exposure of some of the tricks of the trade should have a salutary influence.

LETTERS TO THE EDITOR........................ 314

A 54-in. Wooden Barrel Sewer; Correction—The Cement for the Melan Bridge at Topeka, Kan.—An Experience in Raising a Swing Bridge—"Metallic Structures, Corrosion and Fouling and Their Prevention"—Swing or Lift Bridges for Heavy Traffic—The Resistance of Concrete to Fire—Further Discussion of the Nicaragua Canal Surveys—Specifications for Water-Tube Boilers for the St. Louis Water-Works—Notes and Queries.

THE THREE ELECTRIC LOCOMOTIVES of the Baltimore & Ohio R. R. tunnel line, at Baltimore, O., will soon be used to handle the passenger trains as well as the freight trains. The overhead conductors are being extended ¾ mile northward (to the new Mount Royal station) and 1,500 ft. southward, to obviate the necessity of using steam pusher engines on the tunnel approaches. The electric engines are giving good satisfaction, and the maximum trainload hauled so far has been a train of 41 loaded freight cars with two locomotives not working. The electric power plant is now being used not only to furnish the power for the tunnel locomotives but to run 180 street cars of the Baltimore Traction Co., and also to light the Camden station and yards, the tunnel, the Locust Point freightsheds, warehouses and yards, the Mount Clare shops and the new Mount Royal passenger station.

◆

THE CASCADES LOCK, built by the U. S. government for passing the Cascades on the Columbia River, Oregon, was formally opened to traffic on Nov. 6. The completion of the 3,000 ft. of canal through the rocky gorge of the Columbia River and the construction of this lock was contracted for on Jan. 24, 1893, with J. G. & I. N. Day. It was to be finished in one year from the date of contract, but the unprecedented flood of June, 1894, and other causes delayed the work. The lock is 521 ft. long between hollow quoins, 90 ft. wide and has a low-water lift of 24 ft. The lock and guard gates are built of steel and were furnished by the Maryland Steel Company, of Sparrow's Point, Md. They are of the single-skin type, swinging freely on the pivots without the aid of rollers or flotation chambers. The height of the lower guard gate is 36 ft. above the miter-sill, and the lower lock gate is 46 ft. and the upper lock gate 40 ft. high, with an upper guard gate 54 ft. high. These are claimed to be the highest metal gates ever built; the five gates in the Sault Ste. Marie Canal, built by the U. S. government, ranging from 25½ to 43 ft. in height.

◆

THE DRY-DOCK AT ABERDEEN, Scotland, has become famous among engineers for the deterioration of the Portland cement concrete used in its construction through the chemical action of the sea water. In 1887, repairs were carried out on the dock under the direction of Mr. P. J. Messent, M. Inst. C. E., but the deterioration has continued, so that the engineer to the Aberdeen Harbor Board has just made a report advising the entire reconstruction of the dock at an estimated cost of about $500,000. The action of the sea water on the cement at the Aberdeen dock was fully described in Proc. Inst. C. E., Vol. CVII, pp. 73-198.

◆

ADDITIONAL WOOD PAVEMENTS IN MILWAUKEE are prohibited by an ordinance now pending before the common council of that city. The ordinance also provides that all pavements must be laid on concrete foundations. The ordinance may be amended to permit the use of wood pavements in outlying districts, to be laid on concrete. The requiring of concrete foundations would in itself practically exclude wood, according to Mr. Geo. H. Benzenberg, M. Am. Soc. C. E., City Engineer, who states that in Milwaukee brick pavement is cheaper than wood, if each is laid on concrete.

THE PROTECTION OF MACADAMIZED ROADS is aimed at in an ordinance prepared by the Street and Water Board of Jersey City, N. J. The trucking traffic on some of the avenues has become very heavy since the new pavement was put down, and much damage has already been done. The ordinance provides that vehicles which weigh, with their loads, 2,000 lbs. or over, shall be provided with tires not less than 3 ins. wide, and vehicles weighing 5,000 lbs. or over shall have tiers not less than 4 ins. wide.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week was caused by a rock slide on the Northern Pacific R. R., near Paradise, Mont., Nov. 10. A passenger train ran into the slide and the engineman was killed, while the fireman was badly injured.

◆

A LOCOMOTIVE BOILER EXPLOSION occurred Nov. 5, in the yards of the Southern Ry., at Atlanta, Ga. The engine had just come in from Chattanooga, and was in the cleaners' hands. Two men were killed.

◆

A RAILWAY BRIDGE COLLAPSED under a wrecking train, Nov. 1, near North Adams Junction, Mass., on the Boston & Albany R. R. The derrick had not been fully secured and had slewed so as to strike one of the trusses. The engine and cars went down, but the crew jumped and nobody was hurt.

◆

A BROKEN CRANKSHAFT on the twin-screw steamer, "Fuerst Bismarck," of the Hamburg-American Line, on its latest trip to New York, obliged the vessel to finish its trip with only the port engine working. The crack developed just beyond the after crank cheek of the crank of the low pressure cylinder of the starboard engine. A spare shaft was carried, and this was fitted in place in time to allow the ship to sail on Nov. 14, as scheduled.

◆

A FLY-WHEEL BURST in the power house of the Rochester, N. Y., Gas & Electric Co., on Nov. 6. The wheel was 18 ft. diameter and 42-in. face, and weighed about 20 tons. One of the flying pieces struck the steam pipe above the engine, breaking the pipe and allowing steam to escape, by which the engineer was seriously burned. Other fragments passed through the ceiling of the engine room into the dynamo room above, wrecking it, and putting a portion of the city in darkness. The probable cause of the accident is not given in the press reports, other than the statement that the wheel was defective.

◆

FOUR BOILERS EXPLODED at the Centralia colliery, Shamokin, Pa., on Nov. 7, killing four men and causing a loss of $10,000. The four boilers were in a group of 16. It is stated that one of the men, who was fatally injured, saw steam issue from a crack in one of the boilers, and shouted a warning, but the explosion took place before any one could get out of the boiler house.

◆

A SAW-MILL BOILER exploded at Summersville, W. Va., on Oct. 22, killing three men and injuring three others. Pieces of the boiler were thrown several hundred yards.

◆

THE U. S. BATTLESHIP "TEXAS" sank in the East River on Nov. 9. Fortunately the mud in the bottom of the river in front of the Brooklyn Navy Yard, where the vessel was stationed, was only a few feet below the keel, so that the sinking was not a serious matter as it would have been if it had happened in the middle of the river or at sea. The ship was raised the next day, and the total damage, it is said, will not reach $10,000. The true cause of the accident will not be known until after an investigation by a court of inquiry, which has been appointed by the Secretary of the Navy, but from the imperfect reports now available it appears that it was due to the breakage of a 13-in. sea-cock, through which water enters to supply the condensers, and the filling of the engine-room compartment by water. It is also stated that the bulkhead doors between the engine-room failed to hold water. The accident should lead to a thorough investigation of the water-tightness of compartment doors and of the strength of sea-cocks.

◆

THE LEAKY RESERVOIR AT MONTREAL has been reported on by Prof. C. H. McLeod, of McGill University, and Mr. J. O. A. La Forest, Acting Superintendent. The reservoir has a capacity of 42,000,000 U. S. gallons and is formed by a masonry wall, backed first with puddle and then with an earth and stone embankment. Hook gage measurements, with allowances for evaporation, showed that with 23 ft. of water the level fell at the rate of 2.302 ins. in 24 hours, the test lasting 13 hours, or at the rate of about 350,000 U. S. gallons per 24 hours. With 18 ft. of water the leakage was at the rate of 120,000 U. S. gallons per 24 hours. Mr. La Forest believes the leakage is caused by the ice action near the high water line. Both he and Prof. McLeod recommend that the upper portion of the walls be repointed before cold weather sets in, as a temporary measure. Prof. McLeod suggests that "it might be well to consider the advisability of coating the walls with a waterproof wash." The water committee has been instructed to have the repointing done, as recommended. Mr. La Forest states that the high level reservoir, with a capacity of about 1,900,000 U. S. gallons, leaks 54,000 U. S. gallons a day, making the leakage of the two reservoirs more than 400,000 gallons a day. It costs $8 per day to pump the water wasted, in addition to which the leakage from the larger reservoir passes to the grounds of McGill University where, according to Prof. McLeod, it "constitutes a very serious source of injury to the buildings and grounds of the university."

◆

A MUNICIPAL ELECTRIC LIGHTING PLANT for Des Moines, Ia., is recommended by Mr. John MacVicar, Mayor, after a somewhat extended investigation of the subject. Public lighting now costs the city $53,500, divided as follows: Electric street lamps, $31,696; electric lights for city hall, $2,202; gas street lamps, $5,724; gasoline street lamps, $13,888.

◆

MUNICIPAL BONDS are now in active demand, where a month ago they could hardly be sold on any terms. The city of New York, which in September could not obtain bids for its bonds at all, opened bids on Nov. 10 for 3½% bonds to the amount of $16,000,000. There were no less than 185 bids received and the total of all the bids reached the enormous sum of $181,000,000.

◆

A NEW STEAM GARBAGE SCOW for the city of New York was launched Nov. 9 from the Crescent ship yards of Mr. Lewis Nixon, at Elizabethport, N. J. The boat, which has been christened the "Cinderella," is a twin-screw vessel, formed of two pontoons with a garbage compartment between, having an estimated capacity of 600 cu. yds.

◆

A FAST RAILWAY RUN was made on the Chicago, Rock Island & Pacific Ry., Nov. 8, by a train carrying a party of the Western Society of Engineers from Davenport back to Chicago. The run of 181 miles was made in 3 h. 41 mins., or 3 h. 30 mins. actual running time. The distance of 163 miles from Moline to Blue Island was made in 176 minutes running time, excluding three stops.

◆

MUNICIPAL HOSTILITY TO RAILWAY CORPORATIONS is the main reason given by Judge Biddle at Carlisle, Pa., for refusing the petition of the people of Riverton to have the tracks and property of the Cumberland Valley R. R. and Northern Central R. R. included in the new borough. The former road has large and busy terminal yards, while the latter has a traffic of 40 trains daily. The following is an extract from the decision:

> From recent litigation we know that inharmonious relations exist between the inhabitants of Riverton and the two companies above referred to, and this makes manifest the fact that if the tracks of the latter should be brought into the borough, the business thereon would be liable to be much hampered by ordinances relating to the speed of trains, crossings at grade, employment of watchmen, and other matters in regard to which the authorities of a town are at times prone to legislate. On account of the unusual amount of train work which is done at the locality in dispute, severe damage, both to the stockholders and to the public could be inflicted by an unreasonable or hostile council. We have no hesitation in laying down the broad abstract proposition that it is directly contrary to public policy to unnecessarily subject the corporations of a railway to local municipal control, and, therefore, as no necessity or even reasonable cause for doing so appears in this case, the court would not be justified in granting the prayer of the petitioners.

THE PLANS FOR THE BASCULE BRIDGE over Newtown Creek, Brooklyn, N. Y., have been modified to the extent of increasing the span 24 ft., to give a clear span of 150 ft. clear of the fenders. The designs for the bridge were published in our issue of Nov. 5.

◆

THE WORK OF THE BUILDING DEPARTMENT of New York city during the first nine months of 1895 and 1896 is shown by the following table, which is taken from the quarterly report of Mr. Stevenson Constable, Superintendent of the Department of Buildings:

	1895.	1896.	Increase in 1896.
Applications filed, new bldgs. and alterations	4,228	5,416	1,188
New buildings commenced	2,164	2,175	11
New buildings completed	1,703	2,480	777
Alterations commenced	1,094	1,465	371
Alterations completed	1,105	1,546	441
Iron and steel beams, girders, etc.	58,106	161,162	103,056
Violations of the law reported by inspectors	3,843	4,754	911
Buildings reported by inspectors as unsafe	1,705	2,666	961
Notices issued	10,704	39,457	28,753
No. inspections made of passenger elevators	2,632	4,257	1,625
Unsafe buildings made safe or taken down	1,204	2,510	1,306
Violations removed	2,722	4,628	1,906
Cases forwarded attorney for prosecution	2,714	2,772	58
Pass. elevator cases to attorney for prosecution	16	182	166
Defective pass. elevators reported by inspectors	62	856	794
Made safe on notice from Dept.	44	912	868
Notices of suits issued	5,075	5,284	209
Cases disposed of by attorney	2,841	4,522	1,681
Totals	101,962	247,044	145,082
Money collected by the attorney..	$5,778	$14,337	$8,558

THE STEEL ARCH ROOF FOR THE CHICAGO COLISEUM.

(With inset.)

One of the largest single span steel arch roofs erected in this country since the construction of the great buildings for the Columbian Exposition at Chicago is that recently completed to cover the main auditorium of the Chicago Coliseum, a building designed for convention and exhibition purposes and located about on the site of the "Wild West" show, so familiar a side feature at the great World's Fair of 1893. It is of passing interest to note that this same "Wild West" show was the attraction which inaugurated the recent opening of the building to the public, and perhaps of more interest to some of our readers—of certain political affiliations at least—to note that it was the scene of the struggle which signalized the choice of a Presidential nominee at the Democratic convention held July 7. It is for great exhibitions and assemblies of this kind that the Coliseum is designed. It is the magnitude of its steel roof, however, and not its uses, that makes the structure worthy of description in Engineering News.

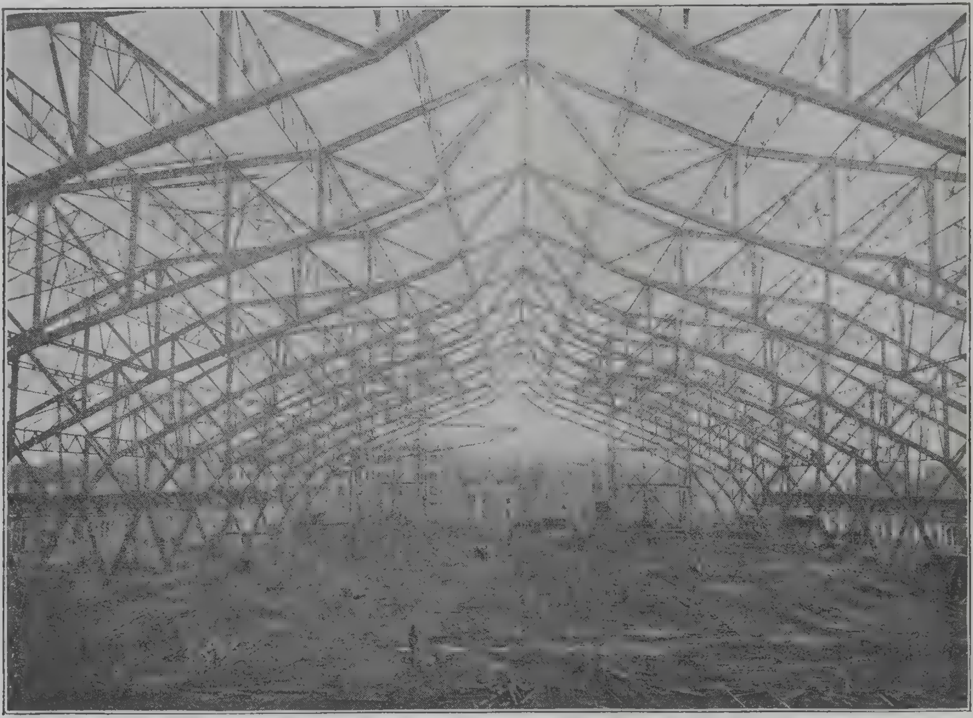

FIG. 11.—INTERIOR VIEW SHOWING ROOF ARCHES CHICAGO COLISEUM

The dimensions of the roof arches of the Coliseum as compared with those of a number of other large arch roofs, are as follows:

---

*These figures of length and width include the area covered by shed roofs and side galleries, except in case of the Coliseum where the end vestibule and ticket office is not included.

Most of the above structures have been described in previous volumes of Engineering News; the two Pennsylvania R. R. train-sheds, Sept. 26 and Oct. 3, 1891, and June 1, 1893; the Philadelphia & Reading R. R. trainshed, Jan. 19 and Feb. 2, 1893, and the Manufactures Building and Paris Machinery Hall, Sept. 1, 1892. No roof arches yet built have exceeded in span those for the Manufactures Building at the Columbian Exposition; and including shed roofs, no building yet constructed has ever had so great an area of ground plan.

As a matter of some interest, the capacity of the Chicago Coliseum as compared with the capacities of some other buildings designed for public gatherings, is given below from figures made public by its architect, Mr. S. S. Beman, of Chicago:

Name of Building.	No. people.	Name of Building.	No. people.
Chicago Coliseum....	50,000	St. Sophia, Constantinople	23,000
St. Peter's, Rome....	54,000	Notre Dame, Paris..	21,500
Cathedral, Milan....	37,000	Cathedral, Pisa......	13,000
St. Paul's, Rome....	32,000	St. Stephens, Vienna.	12,400
St. Paul's, London..	31,000	S. Dominic's, Bologna.	11,400
St. Petronia, Bologna.	26,000	Cathedral, Vienna...	11,000
Cathedral, Florence..	24,600	Madison Sq. Garden..	8,433
Cathedral, Antwerp..	24,300		
St. John Lateran, Rome	23,000		

The manner of seating the large assemblies which the Chicago Coliseum will accommodate will vary somewhat according to the extent of main floor required for exhibition purposes. Two stationary galleries extend around the building on all four sides and these are provided with permanent seats, but the seats on the main floor are movable and will be arranged to suit conditions. Only the weight of the audience in the galleries comes on the framework of the building.

The Chicago Coliseum is 675 ft. 2 ins. long without the vestibule, and 300 ft. wide in its outside dimensions. In Figs. 1 to 4 inclusive, are shown a number of plans and sections which give in diagram the principal features of the steel framework. Corresponding members in the sections and plans are lettered alike, so that reference from one to the other is easy. It is obviously impossible to show within reasonable space the details of all members and the detailed drawings here will be confined to a few of the most interesting features only. From these and the diagrams, Figs. 1 to 4, the nature of the construction will, we think, be reasonably clear.

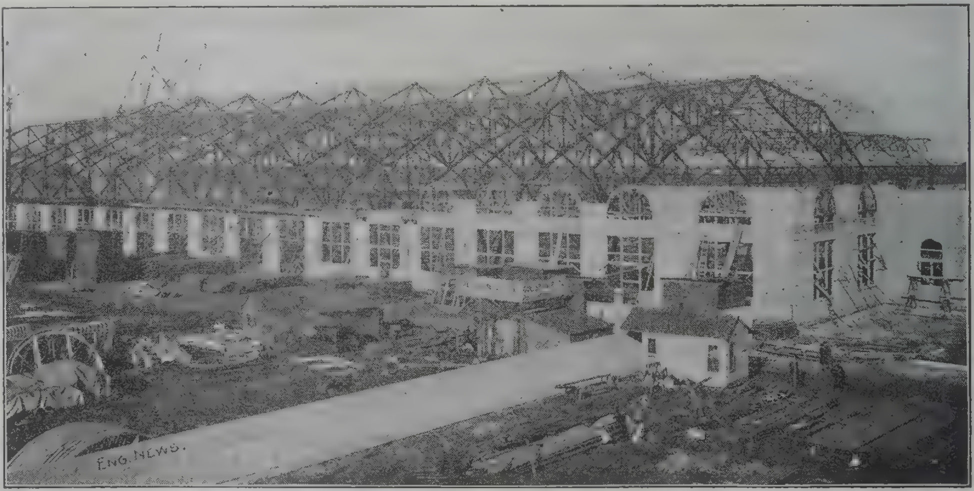

FIG. 12.—EXTERIOR VIEW SHOWING STEEL ROOF FRAMEWORK AND PARTLY COMPLETED SIDE WALLS.

Fig. 1 is a plan of the roof framing, showing the main roof arches, lateral bracing, purlins, shed roof trusses and their supports. Fig. 3 is a part plan of the gallery framing, and Figs. 3a, 3b, 2 and 4 show the above framing in section. There are twelve main roof arches connected in pairs. The two arches forming each end pair have the outline shown by Fig. 5, and the eight forming the four interior pairs have the outline shown by Fig. 6. The main difference between these two styles of arches is at the apices; the apex of each interior arch being raised at the demand of the architect so as to give the building an appearance of height to correspond with its great lateral dimensions, and yet to obtain as far as practicable the advantages of easy heating which a low roof presents. This form of apex was also influenced by the style of skylight framing and roof construction adopted by the architect, as it saved a vertical ridge frame for the ridge skylight and considerable supplementary ironwork; in brief, it was considered a cheaper and practically as satisfactory a construction by the engineer under the conditions imposed upon him. A study of the strain sheet, Fig. 6, showing the apex members will enable the reader to determine for himself the sufficiency of the design. Fig. 2 shows the two styles of arches side by side and also shows the span, height, foundations, etc. It will be noticed, particularly, that the horizontal thrust is taken by the foundations, there being no tie rod between end piers. The strain sheets show this thrust and also the strains in all other members of the arches under various conditions of loading.

The arch roof covers the main auditorium and the shed roof provides for a gallery and extends the main floor beyond the feet of the main arches, as shown by Fig. 2 and Fig. 4. At the side of the building the trusses forming the shed roof and carrying the gallery are carried by the girders and arches Fig. 3b and the wall columns Fig. 2, the construction being quite simple. At the ends the trussing necessary to carry the shed roof is somewhat more complicated, as shown by Figs. 2 and 4, but will be easily understood from the drawings, Sections Y. Z. and N. S. The part longitudinal elevation, Fig. 4, shows the timber roof carried by the steel framework, and it is also indicated in outline on Section Q. R., Fig. 2. This timber roof was used partly for architectural appearance and partly to provide for skylights, the architect fearing that such lights in the plane of the roof would not be satisfactory under snow load and on account of leakage, and also that the cost would be greater.

The framework of the arch roof comprises besides the arches proper 17 lines of purlins and wind bracing. The purlins between the pairs of arches differed from those between the arches of each pair as indicated by Fig. 3a. The purpose of the bracing below the purlins in the latter case is of course for the purpose of holding from lateral motion the lower chords of the arches. With the other type of purlins the lower chord is stiffened simply by a knee brace, Fig. 3a. The wind bracing is in the plane of the top chord of the arches and its character is shown by Fig. 1.

UNIVERSITY OF ILLINOIS

In the foregoing the general arrangement and nature of the steel work is pretty clearly indicated and attention may now be turned to the composition and some of the details of the various arches, girders, purlins, trusses, etc. The main roof arches will be considered first. They are three-hinged arches and the details of chief interest are the feet and bearing shoes and the apices. Fig. 7 is a detail of the arch foot and Fig. 8 details of the shoes. These drawings give all dimensions and need not be described further. Fig. 9 is a detail of the apex of the arches of the form shown by Fig. 6, that is the eight interior arches. This detail is of especial interest in connection with the peculiar shape of the arch at the apex—the reasons for which were stated above.

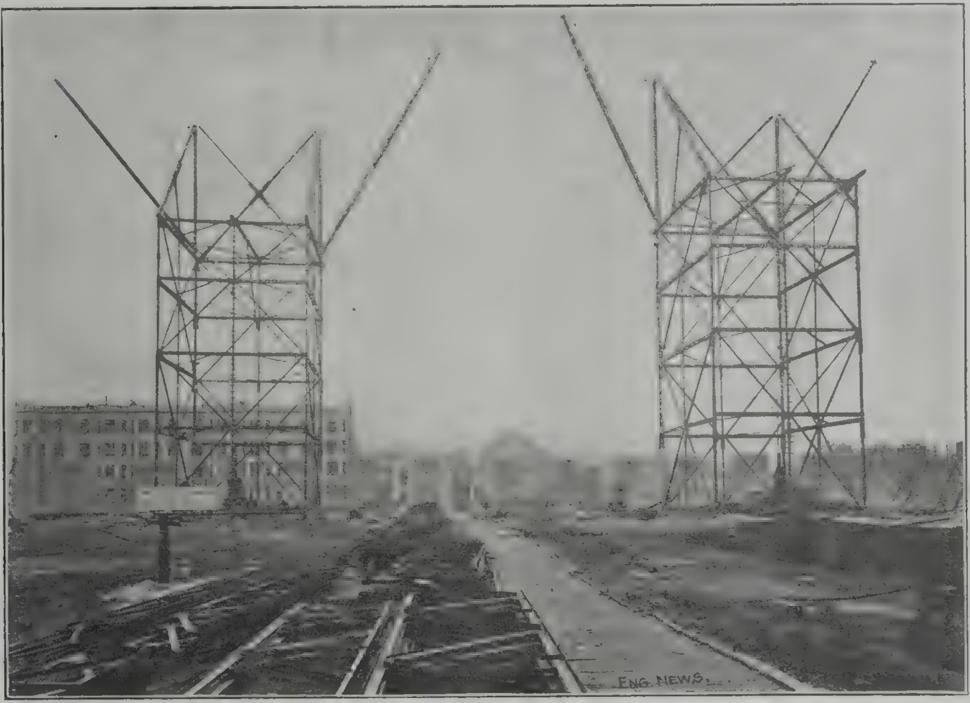

FIG. 13.—VIEW SHOWING TRAVELERS USED IN ERECTING ROOF ARCHES.

The composition of the purlins, girders and other trusses is of one type, viz., riveted triangular truss work. The members consist of one or more angles with riveted plate connections; generally the chords consist of two angles and the web of single angles. The shapes of the various trusses are indicated clearly in the general plans, Figs. 1 to 4. All material was steel and was required to show a tensile strength of 58,000 lbs. to 68,000 lbs., an elastic limit not less than 32,000 lbs., an elongation of 22%, and a reduction of area of 45%. The assumed loads for which the metal work was calculated were as follows:

	Per sq. ft.
Dead load	25 lbs.
Live load, vertical snow and wind	20 "
Live load, horizontal wind	30 "
Purlins:	
Dead load	12 "
Live load, vertical	30 "
Gallery and roof girders:	
Dead and live loads	80 "

In tension the maximum allowable strains were for main trusses 16,500 lbs.; for purlins, 14,500 lbs., and for gallery and roof girders, 15,000 lbs. per square inch. In comparison the maximum strains were, for the main trusses, those obtained by the formula,

$$\frac{15,000}{1+\frac{L^2}{36,000\, r^2}}.$$

and for the purlins and gallery and roof girders, respectively, the same with the numerators 14,000 and 14,500, in the formula. The possible conditions of loading assumed are shown on the strain sheets Figs. 5 and 6.

The extent and general character of the steel work have been pretty clearly shown in the foregoing, but additional clearness will be given to the construction by the photographic views Figs. 11 and 12. The first of these is an interior view along the longitudinal axis of the building and shows the truss work and purlins principally. The second is an exterior view and shows the side walls partly completed and also gives a rather impressive view of the network of roof framing. In Fig. 11 it will be noticed that at the far end one of the roof trusses is being erected, the right half being nearly at full elevation and the left half part way up. The traveling towers used for erection are also shown in this view and more clearly by Fig. 13. Each half arch was assembled complete on the ground and raised into position by tilting up the apex. After the erection of the roof arches the other framing was put in place by means of hoists and derricks placed on the roof.

As the readers of Engineering News already know (Eng. News, Aug. 29, 1895), a serious accident occurred to this building during its construction, and although the data are not available for a full discussion of the causes of this accident, a few words may be said in regard to its occurrence. The accident took place Aug. 21, 1895, after twelve main roof arches and most of the other roof framing were in place, although probably not fully connected, and resulted in the collapse of all but one of the roof arches. The collapse occurred at night when no one was at work, so that no person was hurt, and as far as known it occurred unwitnessed. The accident is stated by the engineer and designer to have been due probably to the fact that roofers had concentrated large loads of boarding and other timber at various points on the roof, thus increasing the strain to a dangerous point at places and at a time when the framework was not in the best condition to withstand it. After the collapse the steelwork was entirely rebuilt and it is of course this second structure that is shown by the illustrations accompanying this article.

The architect for the Chicago Coliseum was Mr. S. S. Beman; the general contractors were the Probst Construction Co., and the designer of and contractor for the steel work was Mr. Carl Binder, all of Chicago. The material was furnished by the American Bridge Works and inspected by G. W. G. Ferris & Co., also of Chicago. The building was erected by the Chicago Exhibition Co. For the drawings from which our illustrations are prepared we are indebted to Mr. Carl Binder.

THE EXHIBITION OF VALVES AND HYDRANTS at New York city, which was to have been held on Nov. 10, has been postponed to Nov. 17. The exhibition will be at the Corporation Yard of the Department of Public Works, 437 East 24th St. All exhibits must be at the yards by Nov. 14. Col. Chas. H. T. Collis, 150 Nassau St., is Commissioner of Public Works, and Mr. A. G. Gear is General Foreman Corporation Yards.

THE TOPOGRAPHICAL SURVEY OF BALTIMORE, MD.

In connection with and as a necessary preliminary to projected municipal improvements in the city of Baltimore, Md., a thorough topographical survey of that city was authorized by an ordinance passed on April 26, 1893. A commission was appointed made up of the Mayor, City Register and City Comptroller, and Col. H. T. Douglas, M. Am. Soc. C. E., was selected as the Chief Engineer of the survey. The first section of the ordinance called for "a thorough, accurate and comprehensive geodetic and topographical survey" of the city of Baltimore, beginning with the recently annexed district. From these surveys official maps were to be made:

> On a scale sufficiently large to show clearly the following details: All streets and alleys as now laid out, with their width between the building lines; the elevation of streets above mean tide, at street corners or at other points, as may be necessary; the dimensions of blocks in feet and inches; all streets not yet opened to be located by dotted lines and their grades established, with a view of conforming to a uniform system of surface drainage or underground sewerage, and the survey made of the unimproved and undeveloped portions of the city shall be such that there may be defined on said map, all streams, water-courses, highways, boundary lines of farms or estates, with the names of the owners thereof; the undulations of the ground to be shown by contour lines representing the different elevations in a manner to enable the establishment of grades, locations of sewers, etc.

The second section of the ordinance provides:

> That plats be also made from said surveys and bound in atlas-form for the use of the Tax Department, City Surveyor and Commissioners for Opening of Streets, etc.; said plats to be made on a scale sufficiently large to show, in addition to the matters contained in the general official map. the following details: The dimensions of each lot or tract of land embraced in the city, with the character of the improvements thereon; the location of all sewers, with their dimensions; the system of water supply, with the location of all fire plugs; all corporation buildings, such as school houses, station houses, etc., all railway lines, and such other details as may be considered requisite.

This work was commenced at once under the direction of Chief Engineer Douglas, and a primary triangulation was made covering 54.7 sq. miles of territory. This was followed by precise traverse and leveling parties, and 1,964 bench marks were established over 26 7-10 sq. miles of area by Dec. 31, 1894. In the same time the topographical party had covered 11,200 acres of territory. The report which gives the above figures also states that the final probable error in the length of the whole base-line was 1 in 354,432 in one line, 1 in 985,334 in another and 1 in 15,000,000 in a third comparison. In precise leveling the computed probable error was 0.614 mm. per kilometer, or less than 1-50th in. per mile. In comparison with similar work by the Coast Survey and Mississippi River Commission this was claimed to be the best on record. The total area embraced by the maps of this topographical survey was approximately 32 sq. miles, though the primary triangulation covered 54.7 sq. miles. The scale of 200 ft. to one inch, or 1:2400, was adopted for plotting the topographic maps, and 40 ft. to one inch for the property maps. The field work was done by transit and stadia, or plane-table and stadia, on the same scale of 1:2400, requiring extreme minuteness and accuracy in drawing. The details of the maps, completed in the field, were to be filled in by direct measurements of directions, or azimuths and distances from each topographic station, with occasional measurements for plotting of details with tape. Free use of the telemeter was made in locating elevations or in tracing contours.

Early in the present year some complaint was made as to the methods and results of this survey, and by joint resolution of both branches of the City Council a committee was appointed to examine into and to report upon the character and condition of the topographical survey of Baltimore. This committee reported in August, 1896, and from their report the following is taken: The committee held six public meetings and heard the testimony of a number of city surveyors, engineers and others interested, and it appointed two experts, Messrs. John W. Donn and John E. Sadler, to examine the work and make tests of the accuracy of the work as they deemed proper.

These experts recently reported that they were satisfied that the work of the triangulation division of the survey had been thoroughly and accurately done, and that the measurements and adjustment of angles and the computations of sides of the triangles had been as accurate as those of any survey ever made. The work of the precise levelling party was also thorough and accurate and the bench-marks established will furnish valuable and reliable data for the use of engineers in any part of the city. But, say the experts, no matter how thorough, accurate and comprehensive may be the methods serving as a basis for such a survey, the results are only valuable when accurately shown on maps of detail.

They then find fault with the methods of securing details for map-making, and say that from the methods adopted it was impossible to show these details upon a map in the manner prescribed by the ordinance. The ordinance calls for all measurements in "feet and inches," whereas all office records and field note-books show that the corners of streets, width of streets, dimensions of blocks, etc., were determined in meters, not in feet and inches. These details were obtained by transit and stadia, and the stadia measurements were generally read only to the nearest meter, and in going over 30 or 40 field-books not more than 1 in 100 measurements is made to a nearer degree of accuracy than one-half meter. One-half a meter is nearly 20 ins., or more than 1½ ft., and when distances are required in "feet and inches" on a map, it is difficult to see how they can be determined when the measurements in the field are made only to meters, of nearly 40 ins.

The work of the draftsmen was found to be excellent, and as they practically merely inked in the completed maps made in the field, they can not be held responsible for errors. The experts then tested the accuracy of field-sheets reported as finished and for the purpose used a Johnson plane-table, a special Fauth alidade, a steel tape and an alinement rod furnished by the Chief Engineer of the survey. They reported that they considered the plane-table and alidade furnished as extremely inefficient instruments for the purpose intended, and not adapted to work of a critical character. The table was very unstable and had neither tangent screws for exact orientation and alinement, nor levelling screws for horizontal adjustment. The alidade, specially designed for this survey, was also an inferior instrument, according to the experts, badly balanced, too light and too small to allow easy handling. They report that without exception every station occupied developed errors in details, on some sheets varying from 1 to 14 ft., and these not in one invariable direction only. The reading of the telemeter to the nearest meter was responsible, for many of the smaller errors; imperfect plotting in the field caused others; and the absence of direct control over the work by a single observer in each party engaged was everywhere apparent. Many important details were omitted and small details on the ground plan of houses were left out, or in error.

Careful examination of the sheets show that the chief object of the engineers was to secure the accuracy of traverse stations, with seemingly scant consideration given to the exact location of topographical details. The record of distances given by stadia to the nearest meter is an evidence of this. On a scale of 1 : 2400, or 200 ft. to 1 in., a measure of one foot is distinctly appreciable, and in standard plane-table work an error of 3 ft. on this scale is annoyingly felt. The report goes on to say that

> This sensitiveness of the instrument makes it unapproachable by any other device or method used, for its excellence in critical work or the work of inspection. Angles measured are correct, although their value trigonometrically may not be exactly known because of the impossibility of protracting them to very small measures of arc. In graphical descriptions, however, such knowledge is rarely required, and if any exigency should call for a statement of trigonometrical value, the finely graduated arc of a transit or theodolite would be necessary for their measures. Topographical studies are best made from graphical delineations and the methods by which those delineations can be most quickly and accurately given, afford the most useful, economical and decisive results. An accurate topographical survey can have but one definition—that the results graphically shown are strictly graded to the power of the scale used. Two-tenths of a foot are definable by a scale of 1 : 600, four-tenths by a scale of 1 : 1,200 (100 ft. to 1 in.), and on a scale of 1 : 2,400, a foot is very easily discernible. In plane-table practice, the whole field encompassed by the scale of the work on a sheet of paper of convenient size is directly controlled by the topographer, and at any time he is able to have under inspection, his work already accomplished.

The experts object to the manner of marking the traverse points, by driving a gas-pipe into the ground under the pavement, for example, and say that these can not be regarded as permanent, and they also find fault with the contour system.

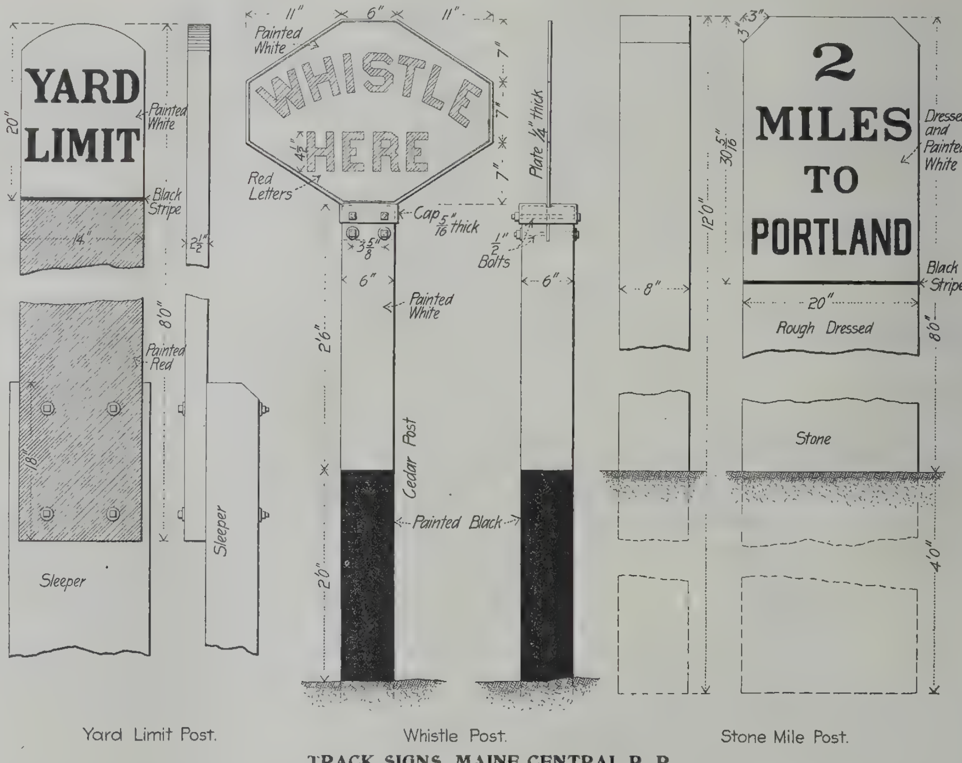
The investigating committee also called in Mr. O. H. Tittman, assistant in charge of the office of the U. S. Coast and Geodetic Survey at Washington. He compared the maps and the ordinance, and testified as follows: That the maps do not contain the width of streets, lanes and alleys, and the length of blocks in feet and inches, nor elevations at street corners, etc., as required by the ordinance. None of these details could be found on the 25 published maps. The committee also called attention to the cost of the survey, which has been $160,000 up to the present time, or about $9.50 per acre of the area covered. As a partial explanation of this excessive cost, more than that of other topographical surveys, it is stated that several thousand dollars were expended in correcting a distance given, in error, by the U. S. Coast and Geodetic Survey, between the Washington Monument and Bay View. The committee deems the money spent in correcting this error as unnecessary, as the distance given was as nearly correct as was required for any operations called for by the ordinance. The committee, in conclusion, recommended a complete suspension of the personnel of the survey, and the suspension of all work until a reorganization can be effected. And this report and recommendation were unanimously adopted on Oct. 12.

* * *

TRACK SIGNS; MAINE CENTRAL R. R.

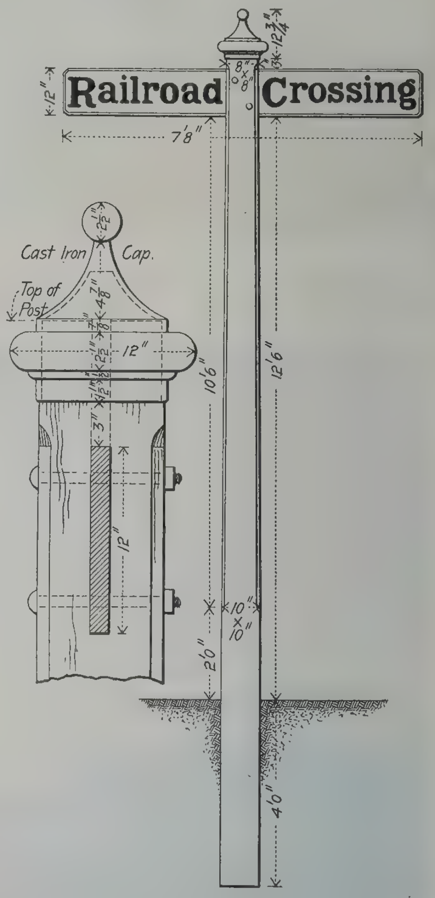
In designing track signs the principal objects to be aimed at are simplicity, durability, and a style that will make them conspicuous. These objects appear to have been attained in the signs illustrated herewith, the blueprints of which we received some time ago from the late Mr. William A. Allen, Chief Engineer of the Maine Central R. R.

The mile post is a rough-dressed stone slab, 12 ft. long, 20 ins. wide and 8 ins. thick, set 4 ft. in the ground, and having 30 ins. at the top dressed smooth for lettering. The unusual height is evidently on account of the heavy snows encountered. The dressed faces are painted with three coats of white lead, with lettering in black and a 5-16-in. black stripe. The post is lettered on both faces, the one shown being lettered "249 miles to Vanceboro" on the back. The yard limit sign is a 2½-in. plank, 14 ins. wide and 8 ft. long, with the bottom bolted to a post or sleeper. The lower part is red and the upper part white, with black letters and a black stripe. The whistle sign differs from the usual style in having the words "Whistle Here" instead of merely a W. It is a ¼-in. iron plate of diamond form, 28 × 21 ins., let 4 ins. into a 6 × 6-in. cedar post whose top is 4 ft. 6 ins. above the ground and is covered with a cap. The bottom of the plate is secured by four ½-in. bolts, the upper ones 7¾ ins. and the lower ones 7¼ ins. long. The post is painted black to a height of 2 ft. above the ground, and thence white. The plate is given two coats of red lead and four coats of white lead, and is lettered in English vermilion.



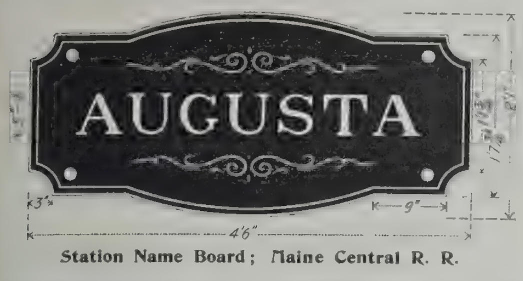
Yard Limit Post. Whistle Post. Stone Mile Post.

TRACK SIGNS, MAINE CENTRAL R. R.



Grade Crossing Sign, Maine Central R. R.

The grade crossing sign is a 1¼-in. board, 7 ft. 8 ins. long, and 12 ins. wide let into the slotted top of a post about 18 ft. 2 ins. long, set 4 ft. into the ground. The post is 10 × 10 ins. to a height of 2 ft. above the ground and then diminishes to 8 × 8 ins. at the top, which is covered by a cast-iron cap. The board is secured by two bolts. The post and board are painted white and the board has a 3-16-in. black border stripe ¼-in., from the edge. The capital letters are 7¾ ins. and the small letters 5¼ ins. high. The station sign is made of two thicknesses of ⅞-in. pine boards, the back board 25 ins. wide at the middle and 19¾ ins. at the ends, and the face board slightly smaller. The boards are put together with four screws and have their edges beveled. The face of the sign is painted black and sanded. The letters are white, with gilt edging, and the scroll work is gray. Over the corner screws are 1½-in. gilt caps. This sign would be better if made with a rectangular board and having the painted flourishing omitted. In this connection it may not be amiss to refer to the almost universal insufficiency of station signs, especially at night, when the board on the platform or hung from the eaves of the platform shed roof is usually in the dark.

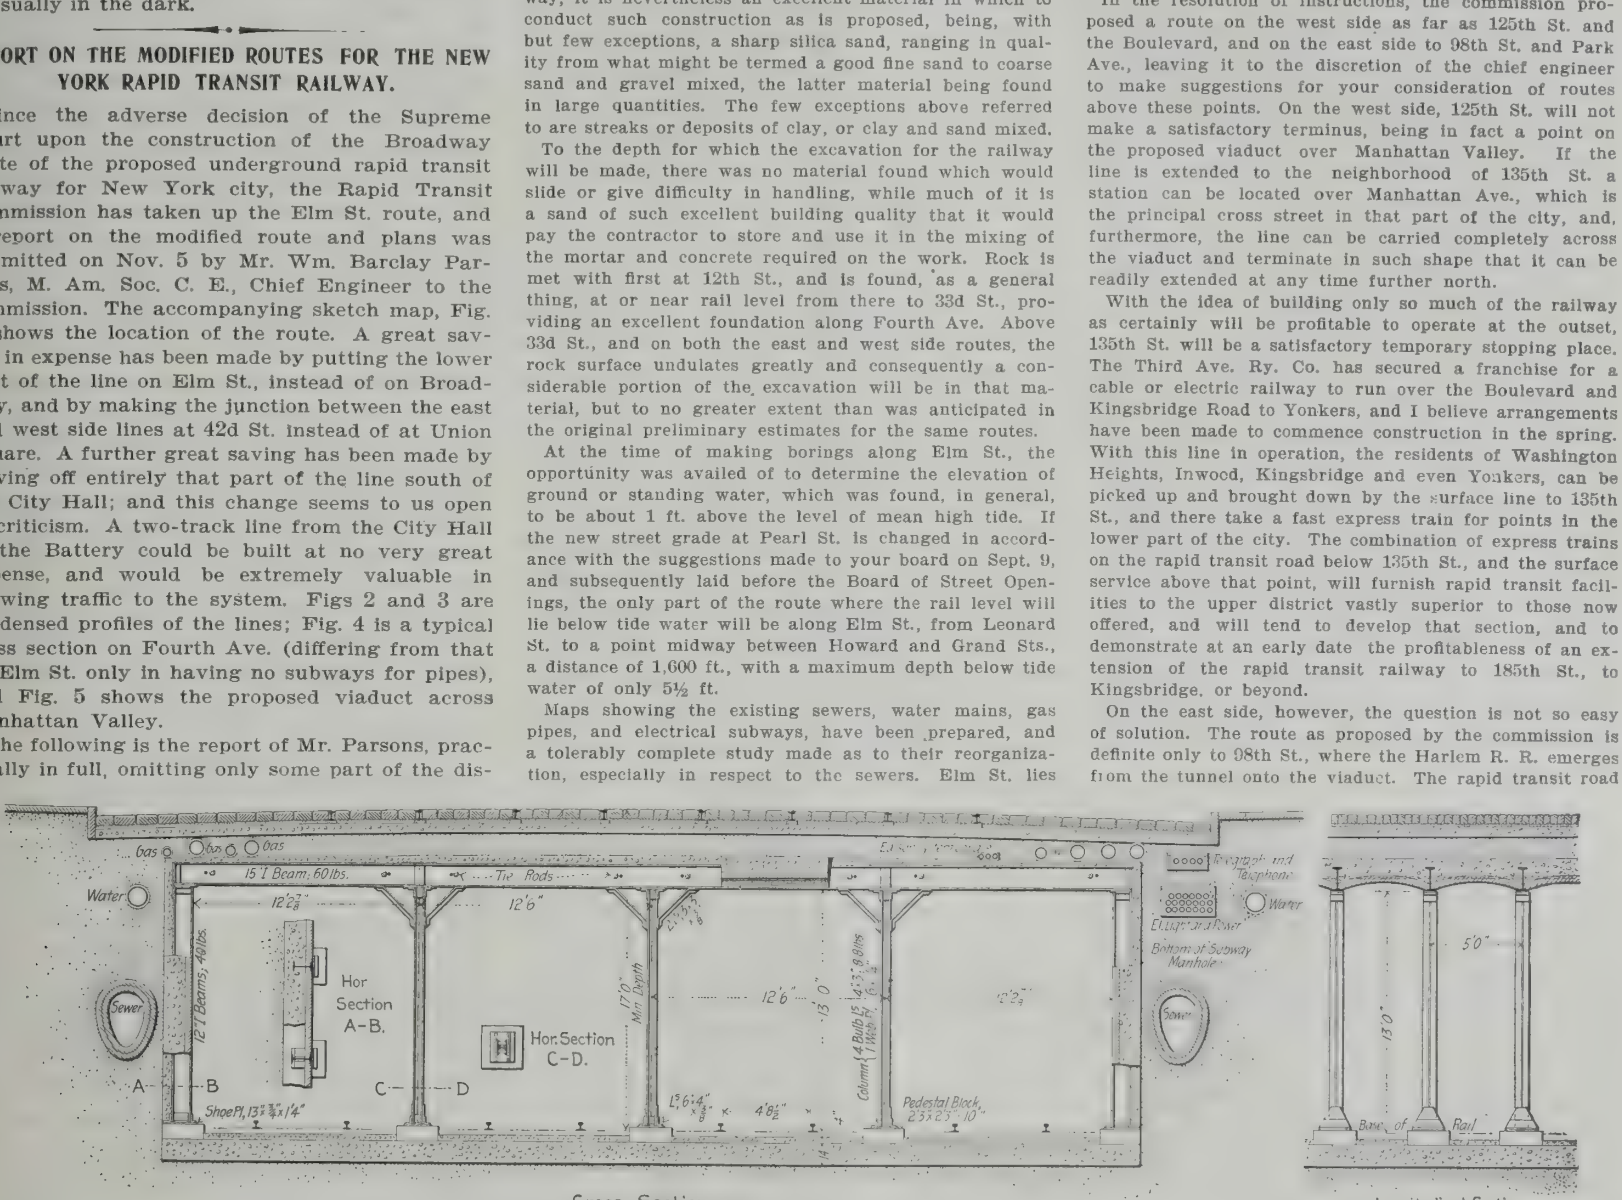


Station Name Board; Maine Central R. R.

REPORT ON THE MODIFIED ROUTES FOR THE NEW YORK RAPID TRANSIT RAILWAY.

Since the adverse decision of the Supreme Court upon the construction of the Broadway route of the proposed underground rapid transit railway for New York city, the Rapid Transit Commission has taken up the Elm St. route, and a report on the modified route and plans was submitted on Nov. 5 by Mr. Wm. Barclay Parsons, M. Am. Soc. C. E., Chief Engineer to the commission. The accompanying sketch map, Fig. 1, shows the location of the route. A great saving in expense has been made by putting the lower part of the line on Elm St., instead of on Broadway, and by making the junction between the east and west side lines at 42d St. instead of at Union Square. A further great saving has been made by leaving off entirely that part of the line south of the City Hall; and this change seems to us open to criticism. A two-track line from the City Hall to the Battery could be built at no very great expense, and would be extremely valuable in drawing traffic to the system. Figs 2 and 3 are condensed profiles of the lines; Fig. 4 is a typical cross section on Fourth Ave. (differing from that on Elm St. only in having no subways for pipes), and Fig. 5 shows the proposed viaduct across Manhattan Valley.

The following is the report of Mr. Parsons, practically in full, omitting only some part of the discussion as to the definite route for the northern or suburban parts of the line:



Cross Section. Longitudinal Section.

FIG. 4.—SECTION OF NEW YORK RAPID TRANSIT RAILWAY ON FOURTH AVE., NEW YORK CITY.

On Aug. 6, 1896, the Board of Rapid Transit Railroad Commissioners passed the following resolution:

> Resolved, that the chief engineer be and he hereby is directed to submit to this board, at as early a date as possible, the routes and general plans for a rapid transit railway, which shall conform to the following conditions:
>
> 1. The total cost, after abundant allowance for contingencies, not to exceed $30,000,000.
>
> 2. The route to proceed from the southern terminus at or near the Post Office, under City Hall Park and Park Row, Elm St. and Fourth Ave., to or near the Grand Central Station, and there to divide into an east side and a west side route. The west side route to proceed under 42d St., Broadway and the Boulevard to a point above 125th St. The east side route to proceed under Park Ave. and over private property to the Harlem River, and across and beyond the Harlem River to as great a distance as the proposed limit of cost will permit.
>
> 3. The railway to have four tracks to the junction of the east and west side routes, and above that point to have two tracks on each route, except that a third track for express service shall be added on both routes where conveniently and economically possible.
>
> 4. The road to be in tunnel, except on the east side route north of 98th St. and on the west side at Manhattan Valley.
>
> 5. The plans to be so drawn as to permit of extension in the future from the southern and northern termini, and of widening the two-track and three-track portions into four-track systems, without unnecessary expense or interruption of traffic.

Along the critical portion of the proposed route, i. e., Elm St., there was no information at hand showing the kind of material that would be encountered in excavating. I therefore caused to be made a series of borings, similar to those made along Broadway. This system of borings commenced at the corner of Chambers and Elm Sts., and extended to the corner of Fourth Ave. and 33d St., so that definite knowledge has been obtained as to the subsurface material. Above 33d St. the result of inquiries made of architects and builders, and the recorded data of sewer excavations of the Department of Public Works, have been sufficient to determine the probable rock line, with enough accuracy for this stage of the proceedings.

While the soil underlying Elm St. is very variable in character, more so in fact than was the case in Broadway, it is nevertheless an excellent material in which to conduct such construction as is proposed, being, with but few exceptions, a sharp silica sand, ranging in quality from what might be termed a good fine sand to coarse sand and gravel mixed, the latter material being found in large quantities. The few exceptions above referred to are streaks or deposits of clay, or clay and sand mixed.

To the depth for which the excavation for the railway will be made, there was no material found which would slide or give difficulty in handling, while much of it is a sand of such excellent building quality that it would pay the contractor to store and use it in the mixing of the mortar and concrete required on the work. Rock is met with first at 12th St., and is found, as a general thing, at or near rail level from there to 33d St., providing an excellent foundation along Fourth Ave. Above 33d St., and on both the east and west side routes, the rock surface undulates greatly and consequently a considerable portion of the excavation will be in that material, but to no greater extent than was anticipated in the original preliminary estimates for the same routes.

At the time of making borings along Elm St., the opportunity was availed of to determine the elevation of ground or standing water, which was found, in general, to be about 1 ft. above the level of mean high tide. If the new street grade at Pearl St. is changed in accordance with the suggestions made to your board on Sept. 9, and subsequently laid before the Board of Street Openings, the only part of the route where the rail level will lie below tide water will be along Elm St., from Leonard St. to a point midway between Howard and Grand Sts., a distance of 1,600 ft., with a maximum depth below tide water of only 5½ ft.

Maps showing the existing sewers, water mains, gas pipes, and electrical subways, have been prepared, and a tolerably complete study made as to their reorganization, especially in respect to the sewers. Elm St. lies nearer the dividing ridge of the city's drainage system than does Broadway, and the taking care of the sewers will therefore be of less serious moment. The Canal St. sewer can be treated in a similar manner to that proposed in the case of Broadway, and approved by the Engineer of Sewers of the Department of Public Works; that is to say, to cut it at the place where the railway crosses, and build a new sewer to the East River, and to turn into that stream the flow from the district lying north of Canal St. and east of Elm St., which now passes west through the Canal St. sewer into the Hudson River. The amount of sewage so diverted will be less than was proposed with Broadway, as the district affected is not so great, and therefore the new sewer will be of smaller size than was previously anticipated.

No part of the route as herein contemplated is a main thoroughfare for water and gas pipes, or electrical subways, while Elm St., being at present with no outlet at either end, contains no pipe of large size, and what pipes are there now, will all be replaced on the opening and construction of the new street. At Fifth Ave. and 42d St. there occurs the most serious pipe crossing along the route, as the large Croton water mains run down the avenue. Fifth Ave, however, at that point forms a decided ridge, the surface of 42d St. falling rapidly both to the east and west. In order to have suitable grades for operating a railway, it would be desirable to pass sufficiently below the level of the avenue to leave all the water and gas pipes undisturbed overhead.

The portions of the proposed route that formed a part of the route previously adopted, were recognized as presenting no serious difficulty in construction. The physical investigations and survey of the newly considered portions show that they contain no features that will cause the road to be excessively expensive, slow, or difficult to build. The proposed route, therefore, escapes entirely the difficulties of construction which were present along Broadway, incident to the heavy traffic, cable railways, complications of sub-surface structures and the care of abutting buildings. The work can be attacked at as many points as can be conveniently operated at once, and the whole brought rapidly to completion at the same time.

In the resolution of instructions, the commission proposed a route on the west side as far as 125th St. and the Boulevard, and on the east side to 98th St. and Park Ave., leaving it to the discretion of the chief engineer to make suggestions for your consideration of routes above these points. On the west side, 125th St. will not make a satisfactory terminus, being in fact a point on the proposed viaduct over Manhattan Valley. If the line is extended to the neighborhood of 135th St. a station can be located over Manhattan Ave., which is the principal cross street in that part of the city, and, furthermore, the line can be carried completely across the viaduct and terminate in such shape that it can be readily extended at any time further north.

With the idea of building only so much of the railway as certainly will be profitable to operate at the outset, 135th St. will be a satisfactory temporary stopping place. The Third Ave. Ry. Co. has secured a franchise for a cable or electric railway to run over the Boulevard and Kingsbridge Road to Yonkers, and I believe arrangements have been made to commence construction in the spring. With this line in operation, the residents of Washington Heights, Inwood, Kingsbridge and even Yonkers, can be picked up and brought down by the surface line to 135th St., and there take a fast express train for points in the lower part of the city. The combination of express trains on the rapid transit road below 135th St., and the surface service above that point, will furnish rapid transit facilities to the upper district vastly superior to those now offered, and will tend to develop that section, and to demonstrate at an early date the profitableness of an extension of the rapid transit railway to 185th St., to Kingsbridge, or beyond.

On the east side, however, the question is not so easy of solution. The route as proposed by the commission is definite only to 98th St., where the Harlem R. R. emerges from the tunnel onto the viaduct. The rapid transit road can be carried up Fourth Ave. along the side of the Harlem R. R. to the Harlem River, as was proposed before. This suggestion, however, met with the strenuous opposition of the abutting owners. If the line be carried to the east of Fourth Ave., it will be brought into close traffic conflict with the Second Ave. and Third Ave. elevated lines, and as these two roads already exist, it seems to me that the people residing in that neighborhood can be served at much less expense, and more immediately, by improving the facilities of those lines, rather than by building new ones.

In studying this question, I have considered the existence of the elevated railways, and have deemed that the best results for the city at large and for the parties who will construct and operate the rapid transit railway, will be obtained by building the new railways as far removed as possible from the present lines, leaving the latter free to take care of their legitimate traffic, but by improved and extended facilities if necessary. The business of the street railways (including the elevated railways) in this city, is increasing at a rate 2½ times as fast as the population. The normal increase in traffic will not only provide a profitable business for the rapid transit road without drawing from existing lines, but makes it appear certain, if the past is any guide to the future, that at no very distant date both the existing lines and that proposed in this report, will be insufficient to properly care for the travel. I have, therefore, endeavored to study out a location that will allow the new and old systems to be developed from independent territory.

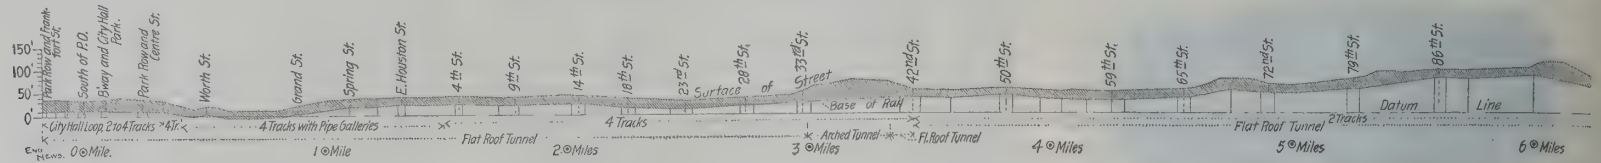


FIG. 2.—PROFILE OF RAPID TRANSIT RAILWAY,

The Board of Experts under Mr. Hewitt, when considering this question, made a suggestion in regard to the desirability of laying out a line in the neighborhood of Lenox Ave. and north of Central Park. North of 110th St., between Eighth and Third Aves., is a portion of Manhattan Island which now supports a large population, and which is capable of supporting a still larger one, but which is wholly without rapid transit lines. This is the best field in New York city for creating traffic. If, therefore, instead of carrying the new route through and along Fourth Ave., or to the eastward of it, it should be carried to the westward of Fourth Ave., it would be removed from the existing railways and serve to create its own traffic, and would at the same time provide rapid transit facilities for a portion of this city's population which is now at an inconvenient distance from the elevated railways.

This region can be served by carrying the rapid transit railway up Fourth Ave., alongside of the Harlem R. R. to 110th St. From that point two alternatives are presented: (1) By laying out an elevated railway along some cross street, as for example 110th St., to Lenox Ave., and thence along and over that avenue to the Harlem River. Lenox Ave. is practically the only street that could be used for that purpose, as Madison and Fifth Aves. are prohibited by law, and Seventh Ave. is open to the same objection that Fourth Ave. would be, namely, that it is too near one of the existing lines of elevated railway. The other alternative would be to branch off at or near 110th St., pass through the rear of the lots abutting say on 110th St., to a point to the east of Lenox Ave., but sufficiently far to the west of Mount Morris Park to avoid the valuable residential property abutting on that square; thence turning to the right with an easy curve and running straight to the Harlem River, parallel to Lenox Ave. The right of way for this purpose from 110th St. would have to be acquired by purchase. This line prolonged across the Harlem River would reach the Annexed District at about 150th St.

The topographical conditions in the Annexed District are peculiar. The tracks of the New York Central, Harlem and New York, New Haven & Hartford railways, with the large yard at 161st St., divide the 23d and 24th Wards in two parts. To the east of the yard there is already a large population; to the west of it, and bounded on the east by the yard and a high dividing ridge, and on the west by another ridge, lies what is known as Jerome Valley, with Jerome Ave. running through the center of it. This valley covers nearly one-half of the two wards, and is entirely without transit facilities. Its surface is such that houses can be erected cheaply and close together, and it provides an area that could, and should, supply homes for a great number of people.

This section, and the other lying east of the railway yard, above mentioned, are two separate and distinct districts and it is impossible for one line to serve both. The easterly district, however, now has the Suburban Elevated Ry. and the Portchester Branch of the New York, New Haven & Hartford R. R., which latter, in connection with the Third Ave. and Second Ave. elevated lines of the Manhattan Ry. system, does a local business with trains at 30-minute intervals.

The Manhattan Ry. has already made certain propositions to your board, looking not only to the improvement and extension of its suburban line, but to the building of a new line which will extend as far north as Mount Vernon and lie well to the eastward of the suburban line. These extensions should be made at an early date and afford immediate relief to the populated portions of the 23d and 24th Wards, and if at the same time a third track were laid on the Third Ave. line, as the Manhattan Ry. Co. proposes, and so enable it to run a continuous express service, the upper part of the city would receive almost immediately a fair rapid transit service—much more quickly than it could by waiting for the rapid transit road itself. It would seem to be wise, therefore, to leave the district lying east of the Harlem R. R., to be served for the present by the improved facilities which can be afforded by the Manhattan Ry. Co. The extension through Jerome Valley could, therefore, be properly taken up as the line of the proposed rapid transit railway. It would be a direct northerly extension of the Lenox Ave. line and would secure for itself a large territory free from competing railways. There are two ways in which a line can be built in this territory. One would be, after crossing the river to build an ordinary elevated railway along Girard Ave. to its intersection with Jerome Ave., and then an elevated line along Jerome Ave. northward to such point as may seem desirable. The other would be, to acquire private property and build a railway (elevated, depressed, or on an embankment enclosed between retaining walls, as the topography of the land will indicate). In my judgment, Burnside Ave. would be a proper point to which to lay out the first installment of construction of this line, although in my estimate I have included the cost of the work to Fordham road. In my opinion, however, this additional outlay would serve a better purpose if applied to the construction of an extension from the Post Office to South Ferry.

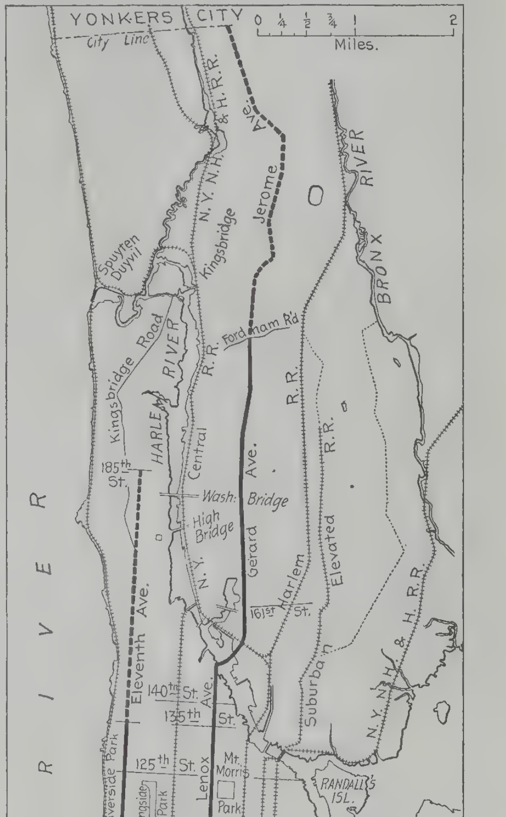

Fig. 1.—Map Showing New Routes for the Underground Rapid Transit Railway; New York City.

The board, in its resolution, determined that four tracks should be constructed to 42d St. On the easterly extension, northward from that point, there is room for but two tracks on the west side of the Harlem R. R., and under or over Park Ave. to 110th St. On the line to the westward, from 110th St. to or near Lenox Ave., I have continued the two-track section, but from 111th St. northward to the Harlem River, I have estimated on a third track to be used for express trains. The station at 125th St. could be so arranged, by proper cross-overs, that an express train could either make a stop at 125th St., or could run through on the third track at high speed, in which case it would have an unbroken run from a point say 1,000 ft. north of the Harlem River, to a station at Fifth Ave. and 110th St., or over 2¼ miles.

On the west side line, I have estimated for a two-track road through 42d St. and up Broadway to 58th St., and a three-track road from there to 98th St. Stations at 60th and 96th Sts., at which points the board had previously laid out express stations, could be arranged in a similar manner to the station at 125th St. on the east side line, so that an express train could stop at either or both of these stations, or, if desired, could make a continuous run from 103d St. to 53d St., a distance of 2½ miles.

As soon as the traffic warrants it, complete four-track roads can be constructed on both the east and west side lines, so as to give a continuous express service, both north and south, at all hours. On Park Ave., north of 42d St., the space on the east side of the Harlem R. R. can be used for the additional tracks.

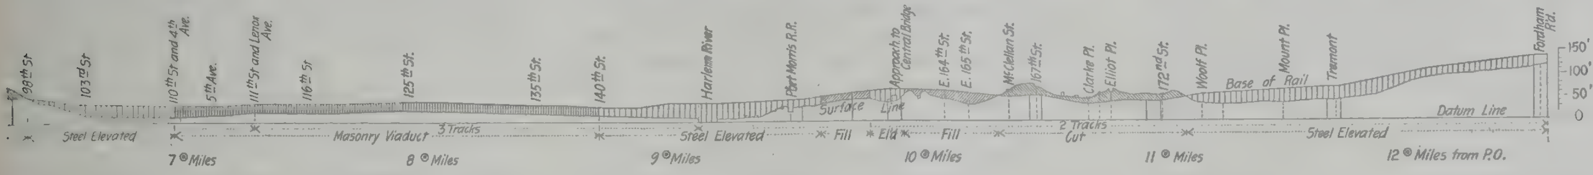
Supposing, however, the trains to stop at 125th St. on the east side, and at 60th and 96th Sts. on the west side, the following schedule, it is believed, could be successfully operated:

East Side.		
City Hall to 42d St.	5½	minutes.
City Hall to 125th St.	21	"
City Hall to north side of Harlem River	24	"
City Hall to Fordham road	35	"
West Side.		
City Hall to 60th St.	11	"
City Hall to 135th St.	21	"

If the 125th, 96th and 60th Sts. stops were omitted the running time from the upper points would be reduced.

The construction designs have been carried only sufficiently far to form a basis for estimates. For the greater part of the route the construction would naturally be in conformity with the detailed plans previously worked out. Along Elm St. pipe galleries have been designed somewhat similar to those previously drawn for the Broadway route. The number of pipes to be contained in these galleries will not be as great as those that would have been provided for in Broadway, and the Elm St. galleries need not, therefore, be quite so capacious. Along Lafayette Place and Fourth Ave., where the street is 100 ft. wide, a plan of construction similar to that previously designed for Fourth Ave. can again be adopted, the pipes resting either directly on the roof of the tunnel or at the side, between the outer walls and the curb lines.

The two and three-track portions of the railway can be widened into four-track systems at any time, without interfering with the traffic, and an extension south from the Post Office under Broadway, as well as extensions north from the suggested east and west terminal, can be made in like manner. The only radical change in construction from the previously considered plans, is the viaduct portion through the blocks north of 110th St. The part of the railway built on private property could be erected on brick arches supported on concrete piers. The streets could be spanned from house line to house line by steel arches, the masonry construction forming suitable and efficient abutments. These arches are designed to give, as the minimum of headroom, 12 ft. at the curbs, and 14 ft. at the centre of the roadway, which is greater than the minimum clearance of the Manhattan Ry. This arch construction, although costing considerably more than ordinary steel elevated spans, gives a structure that will be very economically maintained, one that will bear the heaviest and most severe traffic, one that will be almost noiseless, and one that will diminish the unsightliness of the railway to the minimum. The design is closely allied to the design of the famous Stadt-



NEW YORK CITY. (CITY HALL TO FORDHAM ROAD).

bahn in Berlin, which is very properly considered the finest piece of urban railway construction, where the objections to other similar railways in respect to noise and appearance have been so eliminated that high-class and expensive private residences have been built in its immediate neighborhood.

South of the Brooklyn Bridge Station, at City Hall, a complete loop can be constructed, so that there will be no switching or crossing of express and local trains. As the most convenient location for this loop would be around the Post Office, the opportunity is afforded to have a station in Broadway at that point. The cable pits of the Third Avenue Ry. Co. compel the line under Park Row to be depressed, and it will probably be found convenient to have the Post Office Station a few feet lower than the ordinary stations elsewhere, and thus the pipes in Broadway can be left undisturbed overhead. Two tracks have been projected to serve the Post Office on the Mail St. and Park Row sides, so that direct and constant communication can be had between the Post Office and Grand Central Station and much time saved over the present system of transfer by vans. Other tracks for the storage of trains or for sidetracking temporarily disabled trains can be provided. Should the newspapers whose offices are on Printing House Square and Park Row, desire it, it is possible to construct for them a special track on which, during the night, cars can be set, one or more for each newspaper, and into which the morning editions can be loaded directly from the press rooms through the vaults under the sidewalk. These cars can be taken to the Grand Central Station in five minutes on express trains and so save over half an hour on all papers sent north and east.

In estimating upon the plans herein proposed, the cost of real estate, as well as construction proper, had to be taken into account, as private property to a large amount will have to be acquired. To ascertain the probable cost of construction, profiles covering all the routes have been prepared, and stations located corresponding to the stations previously decided upon by your board in connection with the Broadway plans. The actual quantities of the different classifications of material to be excavated and the value of the material entering into the work, have been carefully computed. Prices have been assigned to the various items after consultation with large contractors and after taking into account the prices used in previous estimates, or as modified by the experience gained in similar work in Boston, or by recent large street excavations made in this city. The quantities taken and the prices allowed are, in my judgment, amply sufficient to complete the work.

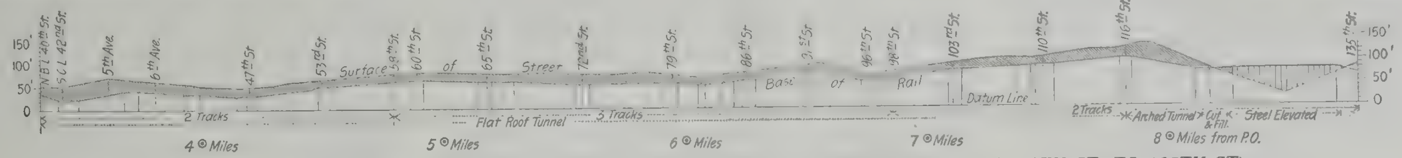


FIG. 3.—PROFILE OF RAPID TRANSIT RAILWAY, NEW YORK CITY. (WEST SIDE LINE, 40TH ST. TO 135TH ST).

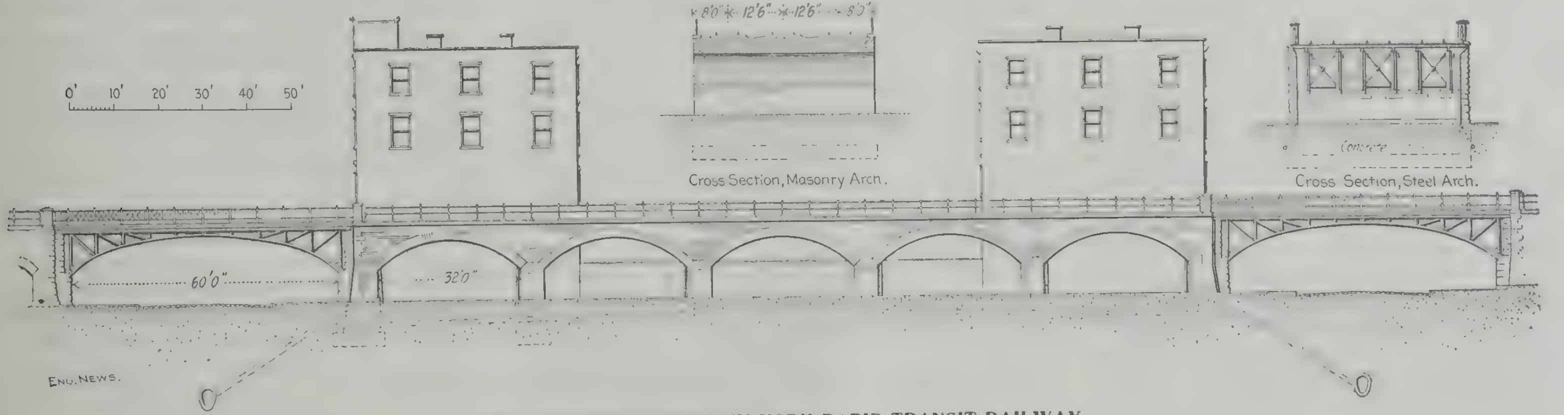

FIG. 5.—VIADUCT FOR NEW YORK RAPID TRANSIT RAILWAY.

The total mileage contemplated by this report is as follows:

Two-track	10.90	miles.
Three-track	3.99	"
Four-track	3.03	"
Total	17.92	"

I believe that the work, as described in this report and its accompanying drawings, including proper terminals and storage places, can be constructed and built in the most substantial and approved manner for an actual cash cost of $20,048,000, with an extra allowance of $1,200,000 for interest during construction. Although, in my judgment, the work can be completed for the sum named, I should advise that an extra arbitrary allowance be made to cover extraordinary contingencies, and such extras as human foresight cannot see. To cover all such contingencies, an allowance of 20% would, in my opinion be amply sufficient.

In order to estimate the cost of the right of way, I procured the advice of those conversant with real estate values, and, acting under such advice as the best means of proceeding, I ascertained the assessed valuation of all land to be taken. From Fourth Ave. to a point near Lenox Ave., I have estimated on a right of way 25 ft. in width, sufficient for two tracks, to be taken from the rear of the lots abutting on 110th St. From 110th St. north, I have estimated on a right of way with a minimum width of 40 ft. and a maximum of 50 ft., according as the lot lines occur. This minimum width of 40 ft. would be amply sufficient for the construction of three tracks. I have had a careful search made of actual sales that have taken place in this neighborhood during the past three years, and on comparing the same with the assessed valuation, I found that the ratio of assessments to sales reported (exclusive of those set down for a nominal sum) is about 50%. Although advised by real estate operators that an allowance of 10% would be sufficient to cover the increased valuations or improvements between now and the probable construction of the road, I have added in order to be liberal, 20%, as in the case of the construction estimate.

North of the Harlem River, a right-of-way width of 50 ft. has been assumed in order to allow for slopes in the cuts and fills, and to provide an ample margin for the addition of a third and fourth track in the future. There will be two other points on the road where property will have to be acquired, first at 9th St. and Astor Place, where the line will pass under the corner of a bloc order to diminish excessive curvature; and the other on Park Ave.,, between 97th and 99th Sts., where the line emerges from the tunnel to the viaduct and where two tracks will take up the whole of the roadway between the buildings and the wall of the Harlem Railroad.

A certain strip would have to be acquired between those two streets in order to make a new roadway. The actual value of the real estate, determined on the basis as herein described, amounts to $3,000,000, and the cost of the railway complete, would therefore be as follows:

Construction	$20,048,000
Real estate	3,000,000
Interest	1,200,000
Total	$24,248,000

If to this be added the very ample amount for unforeseen contingencies already suggested, we have as an outside estimate of money which should be in hand for the work, the sum of $29,097,600.

If the board should prefer to occupy the streets with an elevated railway, instead of using private property, the above estimate will have to be altered to some extent. For the masonry viaduct between Park Ave. and 110th St., to 140th St. (above which point to the Harlem River a steel viaduct will probably be constructed, curving to meet the bridge), the estimated cost is $1,665,040, interest and contingencies included. To build a high grade steel viaduct of the same capacity in regard to tracks, would cost $1,251,792, extras likewise included.

The cost of the right of way in this portion of the route is estimated at $2,537,600, but if an elevated railway were constructed in the street, damages for abutting property would undoubtedly have to be paid. What these damages will amount to I cannot, of course, precisely say. I have conferred with lawyers and real estate experts who have had experience in damage suits against the Manhattan Ry., and they are agreed that it is impossible to foretell, except within wide limits, what amount of damages the courts would be likely to award. The assessed valuation of the abutting property is $6,274,900, and, therefore, on the ratio of 50% between the assessed and actual valuations, the latter would be to-day $12,549,800.

North of the Harlem River the portion of the line which crosses private property to the point where it will reach Jerome Ave., is estimated to cost $698,328, extras included. The most reasonable elevated structure that it would be advisable to construct along Girard and Jerome Aves. for the same distance, would amount to $753,024, or $54,696 more. The right of way over this portion of the route is estimated to cost not over $230,000. As to whether this cost of land will be offset by abuttal damages on Girard and Jerome Aves., it is impossible to state. Probably some damages would have to be paid, but they are not likely to be excessive. The estimate for an outside provision of money falls short of the $30,000,000 stated in the resolution by $902,400. But I understood this limit to be set arbitrarily by your board, as a maximum limit not to be exceeded, and on the other hand not necessarily to be equalled by the estimated cost, provided satisfactory plans could be obtained for a less figure.

I have made no provision for abuttal damages for the portion of the road in the tunnel. In my opinion there would be no damages, or, if in exceptional cases there were any, they would be of insignificant amounts. From 98th St. to 110th St. on Park Ave. a claim for such damages might have more apparent justification, but as Park Ave. between these streets is already a railway street, and as the presence of the rapid transit road on Third Ave. has been considered to augment rather than depreciate the value of abutting property, there would not, in my opinion, be any reasonable claim for material damages here. If, however, any claim for abuttal damages were made and sustained, it is in my opinion clear that it would be met several times over by the sum of $5,000,000, which the Rapid Transit Act added for that purpose.

Changes to standing advertisements must be in hand on Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

The new plan for the New York Rapid Transit railway, which is given in full in another part of this issue, differs from the old plan, which was thrown out by the Supreme Court, chiefly in comprising only those lines that are immediately necessary, and leaving the remaining portions of the system to be added as the growth of traffic makes necessary. The substitution of the Elm St. route for the Broadway line, between City Hall and Union Square, is one which this journal has always advocated. Its effect is to move the line eastward a distance of only 300 to 500 ft. over a distance of less than two miles, but it will make a saving of several millions in the cost of the road, because the road can be built in Elm St. simultaneously with the widening and reconstruction of that thoroughfare. Further than this, the abandonment of the line through the mercantile district on Broadway, will entirely avoid the opposition of the property-owners along that section, which was the main cause of the defeat of the last Rapid Transit plan. It will settle the disputed question of injuries to the buildings along the route, for it was only along this part of Broadway, where the buildings are old and the foundations are shallow that any real question on this point arose. It will also dispose of the opposition due to the proposed appropriation for the road of the sidewalk vaults along the line.

Further than this, the construction and operation of this road in such a manner as to give New Yorkers real rapid transit, will at once bring about a public opinion in its favor that will result in the early extension of three-track or four-track lines to the entire territory which the system is designed to cover.

New York has now a better opportunity than ever before to secure the transit facilities that it has so long needed. The work is in charge of a capable commission, possessing in the highest degree the public confidence, and assisted by thoroughly competent engineers. It is hampered only by the legislation under which it is working, which prescribes a plan for the construction and operation of the road that is difficult and complicated to carry into effect, and which is not calculated to secure to the city the greatest return from its investment. It is to be hoped that the new legislature, when it assembles, may remedy these faults and enable the Commission to proceed unhampered in its work. It can no longer be said that what is proposed in New York is wholly without precedent. Boston has been quietly building during the past two years a subway under its downtown business streets, not to secure rapid transit, properly speaking, but to avoid the blockade in its narrow streets due to the great numbers of electric cars. It has already rented this to the West End Ry. Co. at a price which will make the work pay for itself ultimately without cost to the city.

From a financial point of view, New York's proposed enterprise is far less risky than that which Boston has undertaken and successfully carried out, and it is to be earnestly hoped that the present plan may be carried out without delay.

◆

The present status of the topographical survey of the City of Baltimore, as set forth elsewhere in this issue, is unfortunate, to say the least. As a preliminary to the development of annexed territory and the general improvement of the older portion of the city, an accurate and detailed survey of the existing area was ordered. This work was placed in the hands of an engineer of experience and reputation and up to the present time $160,000 has been expended upon it. The survey was generally supposed to be nearly completed upon a most exact and refined basis, but late objections made to the results as published have caused an investigation by a committee of the City Councils and the finding of this committee is now made public. The expert examination made shows that the triangulation and the precise levelling of the territory in question have been most thoroughly and accurately done, with results which are possibly even more exact than the requirements of the city ordinance would demand. But while the basis of the survey was thus elaborated it is charged that the filling in of the detail was accomplished by methods which could not, and do not give accurate results. The maps made are in error in part and do not give the detailed dimensions in feet and inches, as required by the ordinance, and fail to contain the very information for which the survey was originally ordered.

◆

The experts appointed charge the errors found, varying from 1 to 17 ft. on some sheets, to the adoption of the metric system in the detail work and the reading of stadia rods, in most cases, only to the nearest meter. They object also to the instruments used, stating that they were unstable and not properly equipped for the critical work demanded, and they generally condemn the methods of field work as unreliable, so far as the detailed dimensions are concerned. As a result of the investigation the survey is practically suspended and is being reorganized. A general examination of the reports of the survey and the results of the investigation would seem to indicate that the engineers responsible for this work misunderstood the chief purpose in making this survey. No engineer will object to the extreme care exercised in laying down the basic lines of the survey, nor to the precise levelling done for the establishment of bench-marks for future use; even though this refinement may have cost more money than the city authorities deemed necessary for the purposes intended. But equal care should have been observed in filling in the details of the survey. After all, the valuable and essential result was the preparation of a series of maps accurately showing the detailed surface conditions, with the exact dimensions and elevations plainly expressed upon the maps in a scale sufficiently large for practical use. These maps were intended as a basis for laying out and grading new streets, for designing a comprehensive drainage system and as a record of all existing streets, blocks, structures, water distribution, sewers, etc. It is evident that for work of this character extreme accuracy of measurements was essential and errors of even a foot would be annoyingly felt. The use of the stadia for general topographical work is proper enough, and with careful methods and proper tools the results attained are usually quite as accurate as those obtained with the steel tape and much more rapid and economical. But we believe there is a limit to the refinement to which stadia work can be pushed, and that this limit was passed in Baltimore. With an ordinance calling for the determination and record of dimensions in feet and inches a telemeter reading to the nearest meter, or nearly 40 ins., could not possibly give the results demanded. In the St. Louis topographical survey the stadia was extensively used, but we are told that few buildings or street corners were thus located. With very well equipped and stable instruments, properly graduated stadia rods and the exercise of extreme care, very accurate work can be done; but the report of the experts would indicate that these conditions did not exist in the Baltimore survey and gross errors are frequent. The cost of the Baltimore survey is also excessive enough to have apparently secured more thorough work in all branches. The general cost, including triangulation and levelling, was about $9.50 per acre; while the cost for topography alone is set down at $1.50 per acre, as compared with 73 cts. for St. Louis, and 50 cts. per acre for a survey of 3,000 acres, including mapping and the location of all buildings, fences, railways, etc., in the vicinity of Madison, Ill. The more accurate survey of our older cities is to be always encouraged, and work of this character can not be too well done. But if economy in first cost is absolutely necessary, it may be said that a probable error of even more than 1 in 15,000,000 in a base line is much less likely to affect the useful and practical end of such a survey than an inefficient and inaccurate method of securing detailed dimensions. The trouble in Baltimore seems to have been that the engineers, in aiming to secure an exceptionally accurate and a most creditable base for their survey, either expended too much money upon this preliminary work, or failed to properly appreciate the practical value and necessary uses of the more detailed portions of the survey.

◆

In our report of the test of the Roebling system of fireproof floor construction, in last week's issue, we stated that the maximum deflection of the floor before the water was put on was about 4 ins. We should also have stated that this deflection was greatly diminished after cooling. The day after the test a load of 600 lbs. per sq. ft. was placed on the roof without apparent injury, and when it was removed the deflection, or permanent set, of the roof was found to be only 1⅝ ins.

HONESTY IN THE MANAGEMENT OF CORPORATIONS.

It is a fact which is not always realized at the present day, that the corporation is an essential factor in the modern industrial and economic world. The public, as is well known, is unfriendly to corporations; and it has reasons for its prejudice in the abuses that have attended corporate management; but the fact is that there is scarcely a feature of our modern industrial system which has worked such a vast body of good to the world at large as the corporation. We use the word in its broadest sense, of course, to signify any association of persons, organized according to law, to co-operate with each other in carrying out common ends and sharing common responsibilities, but without the risk which a partnership entails. In fact, "corporation" and "co-operation," though of different etymological origin, have a similarity in significance as well as in sound. It is only by the co-operation of large numbers of men, banded together in a corporation, that the great and beneficent enterprises of this century have been possible. The railway itself, in its present form at least, would be an impossibility without the corporation.

It is seldom realized, either, what an enormous proportion of the world's business is at the present day carried on by corporations, public and private. Every city and organized village or borough is a corporation.. All our railways and street railways, and nearly all our lines of water commerce are carried on by corporations. With a few unimportant exceptions we can say that all the lighting by gas or electricity, all our systems of water supply, and the great bulk of our mining operations, are carried on by corporations.

In the field of manufacturing and of buying and selling, the corporation is a less necessary factor; but here also corporations conduct the bulk of the business and are all the time tending more and more to displace the partnership arrangements which were so common earlier in the century. Corporations conduct also all our banking and insurance business, such necessary factors in the modern business world.

The great transformation in methods of business, which has accompanied the transfer of business from private hands to the hands of corporations is also not fully realized even by intelligent people. For example, nothing is more common than to hear as an argument against a city undertaking the work of lighting its own streets, or even furnishing itself with a water supply, the statement that such things should be left to private enterprise, so that the man who carries them out will be influenced by self-interest to perform the work in the best and most economical manner. The fact of the case is, however, as every one realizes who will stop to reflect, that the actual carrying out of such work, is, and must of necessity be, put into the hands of men who have no financial interest in its results, no matter whether the city does the work or some private corporation. We thus arrive at the truth that the carrying out of the great bulk of all modern enterprise must of necessity be done by corporations, either public or private; and the difference between the two classes is not so great as is sometimes claimed.

In the change which has taken place from individual enterprise to corporate enterprise, at least one great sacrifice has had to be made. We have had to part in some degree with the motive of self-interest as an incentive to good work. The man who runs his own business will ordinarily try to carry it on in the best manner possible, so that he may get the greatest returns. The man who in managing the same business on a salary has no such incentive. But in practically all industries carried on by corporations, this sacrifice must be made. The managing officers of railways, electric light plants, gas companies, etc., have as a rule no financial interest in the companies which they serve. Even when they do own some of its stock they have opportunities to make a hundred dollars by playing false to their trust for every dollar they could make through honest management in the shape of increased returns upon their stock. In fact, the temptations which beset the officer of a great railway corporation, for example, are in many respects similar to those which are set before city officials. We hear a great deal of corruption in municipal affairs; but we question whether the percentage of fraud and acceptance of "commissions" among city officials is any greater than it is among the officials of private corporations of similar size. Or, since we by no means believe in the total depravity that is frequently charged against city officials, let us say that we believe that the honest and faithful administration of positions of trust is as high among the responsible officials of cities at the present day, as among the responsible officers of great corporations.

It will be noticed that we are especially confining our comparisons between the public and the private corporations to those of large size. It is of course true that there are very many minor corporations in which the active manager is also the principal owner, and in which therefore the principle of self-interest as an incentive to good management is operative. But the tendency of the times is not in this direction; but all the other way. The great corporations doing business on an enormous scale are the ones that survive in the competitive struggles; and in the cases where a keen business man builds up a great industry of which he is the owner and manager, it is almost invariably the case that the lapse of a few years sees its ownership in the hands of his heirs and its active management in the hands of men who own no interest in the business.

Further, as respects our great corporations, we are very far from saying or believing that their active managers are, as a rule, false to their trust. On the contrary it is a remarkable evidence of the improvement in public morality and business integrity which has gone on during the present century, that it should be possible to place such a vast proportion of the world's industries in the hands of men whose moral integrity is the sole guarantee of faithful service. Every thoughtful observer of modern life cannot fail to be impressed with the fidelity with which thousands of men carry on the business entrusted to them year after year, handling affairs and funds of great magnitude with the same interest and zeal as if the business were their own, and content to receive a not always generous salary as their sole reward.

But there is another side to the picture, and in fairness that also must be drawn.

The responsible managers and heads of departments of a great corporation have always before them temptations to make gains, which if not dishonest, are at least incompatible with a high sense of moral integrity. It is very often possible to so manage a corporation's business as to cause the market price of its stock to move up or down, and the man who can cause these fluctuations can reap sure profits on the stock exchange. Again, every great corporation must of necessity have important agreements with other or subsidiary concerns, and there are mines of wealth here to the unscrupulous official. We may take for example the operation of freight cars owned by private car companies. It is well known that these cars return great profits to their owners, and are kept running while cars owned by the railways themselves are left to stand idle. It is claimed that ownership of the stock of these private car companies by officials high in authority in the railway companies is one reason why the practice continues despite efforts for reform. In another field, it is well known that the profits made by "construction companies" are not seldom recorded by a "vest-pocket" bookkeeping, which for good and sufficient reasons is never made known to the holders of the corporation's securities. Shrewd observers believe that a good part of the incentive for the great railway construction of the years 1885 to 1890, as well as of the present rage for electric railway construction, is not so much the profits that will accrue to those who own and operate the completed railway, as the fortunes to be reaped by contractors, construction companies, land companies and similar organizations from the building of the lines.

But there is no need for us to specify in detail the methods by which corporation officers can if they will grow rich on small salaries. The main point we wish to show is that these temptations exist; and that a certain percentage of men yield to them to a greater or less degree.

Turning now to the case of city corporations, we find that those who have drawn the charters of most of our cities, have apparently been wiser than the directors of private corporations, with respect to their appreciation of the temptations which beset corporation officers. The officers of almost all cities are obliged by law to let all contracts of any magnitude by public advertisement. Definite specifications must be prepared upon which bids must be received and publicly opened. We are aware that this requirement is considered a burdensome one by some engineers, especially when coupled, as it sometimes is, with the requirement that the proposal of the lowest bidder must be accepted. But the actual results of this system during many years have proved so satisfactory that we believe the directors of private corporations might well inaugurate a similar practice. It is an old and true saying, that the best way to make men honest is to keep them honest. Many men have yielded to temptation who would never have done so had not they felt that they were absolutely secure from being found out. Experience has proved that the best safeguard against frauds and dishonest transactions in business of every sort is thorough publicity. The general adoption of this principle has done wonders in the purification of the business of our cities, and it is equally applicable to the affairs of private corporations.

It will not be overlooked that the public advertisement and letting of contracts operates also as some check against loss to the corporation through the mere inertia, conservatism or lack of enterprise of its managers. In how many cases is a contract awarded by a private company without any attempt to secure competition and lower prices? The excuse given for this proceeding is a familiar one. The officer who let the contract knew the parties to be a reliable firm, who would do a good piece of work and so he gave them the contract rather than bother with several other firms which he knew nothing about. But if we suppose a case of importance where a large amount might have been saved by open competition, was it not his business to secure it and provide proper safeguards to ensure responsibility and good workmanship? Have not the stockholders of a corporation as much of a right to the benefit of the lowest possible price as have the taxpayers of a city?

We are well aware that in the case of cities the method of open competition is often objectionable from its lack of flexibility, which is one of the evils which seem to be inseparable from any business which is carried on by a governmental body. The red-tape and its delays are often irksome and costly.

But the private corporations in adopting this system are held by no such restrictions, and can have its benefits without its drawbacks. It is as effective, for example, for a board of directors to advise their executive officers to let all contracts in open competition, except when good reasons exist against so doing, as it would be to pass a mandatory resolution.

As most of our readers are aware, the practice of publicly advertising contracts of all classes is rapidly growing among private corporations. We believe that as the likeness between these organizations and municipal corporations becomes more generally realized the custom will become still more common, to the great advantage of the corporations' security holders.

LETTERS TO THE EDITOR.

A 54-in. Wooden Barrel Sewer.—Correction.

Sir: Permit me to call your attention to some errors in the description of the wooden outfall sewer in your issue of Nov. 5. These plans are not of sewers actually constructed in Brooklyn, but are adapted from plans of similar sewers of different sizes. The titles under the two illustrations were interchanged. The paragraph relating to creosoting should read: "The 'streaks' or staves are creosoted with 10 lbs. of dead oil of tar per ft. (of timber), weighing 8½ lbs. (per gallon), at 120° F." The error in the last paragraph is doubtless due to an oversight of my own. Yours very truly,

J. C. Meem.

Municipal Building, Brooklyn, N. Y., Nov. 6, 1896.

(The last paragraph states that the "sewers are built in elliptical or other shapes as well as circular, according to necessity."—Ed.)

The Cement for the Melan Bridge at Topeka, Kan.

Sir: In your issue of Oct. 29, I notice some further discussion of the cement for the Melan bridge at Topeka, Kan. In the original specification for cement for this work (which specification was fully discussed in your issue of May 7, 1896), there was a paragraph as follows: "It is not probable that any American natural Portland cement (so-called) will meet these requirements." It may be of interest to your readers to know that the later specification for the work in question, issued Sept. 2, 1896, is a revised form of the original one and does not contain the clause above recited, reflecting upon the character of American Portland cements.

This is no doubt due to the article originally published in your editorial columns and the discussion it brought forth. The thanks of American cement manufacturers are due to you for the fair treatment received in this matter. Yours truly,

American Cement Company,
R. W. Lesley, Vice-President.
22 South 15th St., Philadelphia, Nov. 4, 1896.

An Experience in Raising a Swing Bridge.

Sir: I have read your article describing "a device for raising swing bridges" with a good deal of interest, but think that Mr. Roemheld is late in mentioning it as his invention, as I made use of practically the same scheme nearly four years ago. In January, 1893, I was requested to examine the drawbridge across the Ouachita River, near Columbia, La., on the line of the Houston, Central Arkansas & Northern Ry. I found that the pier upon which the turntable rested had settled upstream to such an extent that the bridge was 1½ ins. out of line and ⅞-in. out of level. I was then 300 miles from Little Rock without any tools other than a hammer and a monkey wrench, and only a couple of men to assist me. I found some old plates in the yard where the iron for the bridge had originally been stored and with these and some stove-pipe iron proceeded to level up the span. In front of each of the six wheels, three of which were exactly under the vertical line of each of the two lower posts, on the low side of the drum, I laid a plate ⅛-in. thick, so placed that I had 3 ins. of room to make a run for the plates. The three wheels under each of the lower posts together covered one segment of the lower wheel tread. I turned the draw towards the plates, running each of the wheels, six in all, upon its respective plate, and then stopped. I next placed a ¼-in. plate behind each of the six wheels and reversed the operation, running the wheels up on the ¼-in. plates. I repeated this operation, see-sawing backwards and forwards until the drum was level. I then proceeded to level up the tread, which I did by forcing plates under each of the tread segments, excepting the two upon which the six wheels rested, spacing these supports about 12 ins. apart. In the middle of this operation it was necessary to open the draw for a steamboat to pass through, and although the tread was only supported with scrap iron we had no trouble, and at no time were trains delayed. Having the tread level all round the circle, I then tamped a rust joint under it, and took out the scrap iron plates, which of course had only been placed there temporarily. After the completion of the work every wheel in the circle took bearing in all positions of the draw. The span above referred to was a 360-ft. draw, single track. In comparing this method with that used by Mr. Roemheld, I prefer using the flat plates, as it is no trouble to run the wheels up on a plate ⅛-in. thick, and when it is there, there is no fear of its running back as is likely to occur in using wedges.

Yours truly, E. T. Terry,
Terry & Tench Construction Co.
Railroad Ave. and 135th St., New York city.
Nov. 7, 1896.

Metallic Structures, Corrosion and Fouling and Their Prevention.

Sir: Will you allow me a few lines respecting your review, in your issue of Oct. 15, of "Metallic Structures, Corrosion and Fouling," as it impugns my professional status. I am not "a professional book-maker." In this country it would be impossible for an engineering one to exist, notwithstanding any liberalities of the publishers.

As far back as 1866, I was assistant resident engineer on the extensive Limehouse Dock Improvement Works, London, constructed without the intervention of a contractor. I have also had sole charge of the construction of many miles of railway and been engaged in general engineering practice, and in addition, for some 20 years, had much to do with anti-corrosive and anti-fouling paints, dozens of steamships and metallic structures having been attended to and coated through my instrumentality; the subject of corrosion and fouling has therefore been constantly before me.

In my books I record what I know and refer to the special experiments and unique experiences of others, acknowledging the source of information and so endeavor to offer as much news as possible, even though some paragraphs may appear to be contradictory. The subject is a very wide one, and to attempt to absolutely determine the relative corrosion of different kinds of iron under every condition of manufacture and use would only mislead. Flaws, which the microscope can alone reveal, have their influence, as you well know.

I am practically acquainted, as a civil engineer, with the subjects upon which I have written books, for they are connected more especially with railway and dock work. The book "Scamping Tricks," to which you refer, I wrote to record those I have seen and heard of on various works; and it was favorably reviewed in your columns. I trust writing a few books does not make one a "professional book-maker," or kind of engineering outcast.

I thank you for your review of "Metallic Structures," and for the expression, "the book contains a great quantity of useful information." I may say all the reviews in technical press here, some nine in number, have been most favorable. If attention and some light has been directed to the matter of corrosion and fouling and paints through my book (and I know of none other for engineers on the subject) I am satisfied; as, although I'm afraid you do not think so, the labor of writing such a work is very considerable and by no means professionally remunerative. Apologizing for trespassing on your valuable space,

I am, yours faithfully,
J. Newman, Assoc. M. Inst. C. E.
Logan Villas, Bath Road, Hounslow, England,
Oct. 27, 1896.

Swing or Lift Bridges for Heavy Traffic.

Sir: I have read with great interest your discussion upon movable bridges in your issue of Nov. 5, illustrated by the designs made for the Newtown Creek bridge. You say: "But when we come to narrow channels, and especially those where a large traffic is moving, the swing bridge is no longer so satisfactory." I beg to differ from your limitation "where a large traffic is moving." The swing bridge gives two passages of even greater width than can be given by any other system, through which two sets of vessels may pass at once, thus doubling the capacity of the bridge. The true place for a bascule or lifting bridge is over a narrow channel where the central pier would offer too much obstruction. Where there is room enough, it is my belief that nothing can excel the swing bridge for durability and certainty of operation.

The whole question was very carefully considered by Mr. Birdsall and myself in designing the two Harlem River bridges, and we see no reason to differ from the conclusion, then reached, that a swing bridge with two openings best accommodated the river traffic. For certainty and rapidity of action, we believe it excels any other form, and that best accommodates the land traffic.

A swing bridge can be so designed as to require the least possible power to move it. The real use of the power machines is to hold it against high winds.

T. C. Clarke, M. Am. Soc. C. E.
New York city, Nov. 7, 1896.

(The passage quoted from our editorial was somewhat ambiguous. What we should have said was, that a swing bridge is not so satisfactory for narrow channels, especially for narrow channels where the water traffic is heavy. In the case of bridges which are only opened once a day or once a week, we have no doubt that the swing bridge is the best type, even for narrow openings, where the pier has to be set to one side of the channel and a structure with unequal arms has to be built.

Our correspondent would limit the use of lift bridges to openings so narrow that a center pier would be an obstruction; but it is a matter of judgment as to when a center pier does become an obstruction. There come to our notice quite frequently accidents in the shape of collisions between swing bridges and vessels; and in a narrow and winding steam especially with a tidal or other current, it is frequently a difficult matter to tow a vessel or string of barges through the narrow opening without fouling something. Clear openings of the width of those on the Harlem River bridges, however, are probably wide enough to give all needful safety to traffic. It was openings of less width that we had chiefly in mind in our argument that the lift bridge should be considered as well as the swing bridge when the design of a structure is to be fixed.—Ed.)

The Resistance of Concrete to Fire.

Sir: In reference to the tests of various systems of fireproofing now being conducted by the Department of Buildings in this city, your short editorial in your last issue hardly does justice to the importance of the knowledge gained by them. In it you mention in reference to the Roebling test, the ability of the cinder concrete to withstand intense heat and sudden cooling. This has now been definitely proved in a second test under even more stringent conditions than the above. In the Roebling test the concrete might have been sufficiently protected by the metal lath center which upheld the arch. On Nov. 7, in a test with a fire of equal volume and temperature, the cinder concrete had no such support whatever, being laid as a beam between the I-beams; and this so withstood the effects of white heat and the shock of sudden cooling under water at sufficient pressure for sufficient length of time to ordinarily dislocate a 12-in. brick wall, that after completion of the test it was in as perfect condition as it would have been had there been no fire at all and the water only applied. This should place at rest any doubt as to the fire resisting ability of such concrete. The tests were also valuable in showing the non-conductivity of the concrete. At no time during either of these tests was the upper surface of the material too hot to handle, and although no temperature was taken of the same, I doubt whether it exceeded 150° F., about the same as that of the outside of the 12-in. walls.

But next to these two points, the most important knowledge gained was the power of the beams to both carry the load and withstand sudden cooling under such conditions. In the Roebling test the deflection of 4 ins. was largely due to loss of strength in the beam carrying the flooring, due to its heating, and the diminution of deflection after cooling demonstrated the return of strength. But the suspended ceiling which was supposed to protect the beams, gave way early in the test, exposing the lower flanges directly to the intense heat. Immediately before the application of the water when the furnace was opened these were at a white heat. I feared at the time that the application of water would cause a "firecrack" in the steel, but the latter came through the ordeal practically uninjured.

Is it not now of as much importance to ascertain the action of the steel beams under intense heat as that of the materials hitherto designed to protect them? These tests are very interesting and of the utmost importance and the lessons we are learning are changing our ideas as to design of fireproof work. The result of tests when reduced to a unit of comparison will not longer be so much as to the resistance of the "fireproof" layer as to the relative resistance of the I-beams, with various methods of protection. The moment of resistance or maximum fiber strain of the beams as shown by deflections will be the guide for determination of results.

Yours truly,
Oscar Lowinson, Jun. Am. Soc. C. E.
39 Cortlandt St., New York, Nov. 9, 1896.

(The test of Nov. 7, referred to by our correspondent, is described on another page of this issue. We fully agree with our correspondent that these tests are of the greatest value to engineers and deserve careful study by everyone interested in any way in fireproof construction. The lessons learned from these tests will greatly influence the designs and specifications for fireproof construction in the future.—Ed.)

Further Discussion of the Nicaragua Canal Survey.

Sir: Regarding the criticisms of the Nicaragua Canal route and the proposed new schemes, it must be apparent that their source is from persons whose knowledge of available data is either immature or entirely wanting. This is well stated in Mr. Le Baron's last letter in your issue of Nov. 5, referring to the report of the U. S. Commission. Its injustice, in view of the high standing of its members, in their criticism of the Canal Company's data, is only explainable by lack of complete information; although it is supposed they would have gathered some new data.

In my capacity as chief draftsman and chief of party for nearly four years in Nicaragua I can fully realize the justice of Mr. Le Baron's claims, although he is not familiar with the work of the last three years, which was very extensive. The problem of a location of the canal in the lower San Juan valley has been thoroughly investigated by many engineers eager to establish this possibility, and the experience of all fixes the impracticability of a dam of any height on the river lower than Ochoa. The only points at which such a scheme would be feasible on the Nicaraguan side are at Serapiqui, Tamborcito, and Tamborgrande. At the first there is a hill on the Costa Rican side which promises well but it is surrounded by swamps, as was proved by both Mr. Le Baron and Mr. Davis. These gentlemen ably investigated the Costa Rican side of the river at the other points with similar conclusions.

I was anxious to make the attempt to solve this problem and under the dircetion of Division Engineer Davis I made a careful examination of the south bank of the river from near Ochoa to Tamborcito, extending my work from two to three miles back from the river and found nothing available as a dam site except near Tamborgrande, and to my extreme disappointment the hills at that place have no connection with any spur from the Costa Rican mountains, except by connecting up various isolated hills across long stretches of very bad swamp. This district is well known to the rubber hunters, and I took every opportunity to question them both at Greytown and along the river; and all agree in saying there are no hills near the river. This is an established fact and the problem is reduced to operating a canal with low lift locks in conflict with the great floods, or the present route, avoiding these as far as possible. The latter offers the great advantages of less risk, less cost, greater facility for operating and greater permanency. These are things that must appeal to all men, irrespective of engineering training.

As to the Salinas Bay terminus for the canal, Mr. Miller certainly cannot devise any scheme for reaching it except by flying. As to the canal project in its present form: The engineer must make the best of existing conditions and there is abundant evidence to show this has been done with rare fidelity. No doubt some of the conditions are not ideal for a canal, yet the project is certainly most feasible. All the different schemes have had careful consideration and the present plan is merely the survival of the fittest, the result of most mature judgment and unquestionable ability, and in the light of many years actual contact with the data, and is not controvertible except in an equal light.

It has been my good fortune to become intimately acquainted with two of the great existing canals since leaving Nicaragua and the difficulties to be overcome there in comparison with these are apparent to me in quantity not quality. The cost estimated is most liberal in view of recent progress. Dredging, for instance, as low as four cents per yard; rock excavation at 79¾ cts. a yard now nets the contractor a large profit. The eagerness of contractors to take the work at estimated prices is a complete vindication against any criticism of under-estimated cost. As to quantities, no data for a work of such magnitude have ever been taken so carefully and completely, and in the case of earthwork, the data would serve for a final estimate to the contractor. As to the criticism regarding incomplete data; to obtain them with the nicety that seems desirable, would require many years and an enormous outlay, could be only comparatively accurate, and finally be only useful as dependent on the judgment of the engineer. Such nicety is only useful and obtainable in the abstract, not in dealing with the concrete, as is shown in dealing with all engineering structures. The devices of the successful engineer in treating with these problems may be quite questionable, depending as they do on his judgment; yet bridges, arches, etc., were built before science was formulated. The data for designing in all the problems of the canal are known within the limits of accuracy, so that they can be used practically, and the sole idea has been to give unquestionable safety, not to figure to a least cost basis at the expense of safety. This is not permissible where the slightest accident after completion might mean irretrievable ruin to the enterprise. If the abstract values of the gagings, etc., could be placed at the disposal of the most eminent theorist his conclusions as to use in design, without actual years of experience on the ground, would not only be faulty but even dangerous to follow.

The points I wish to emphasize, in addition to those presented by Mr. Le Baron, are: that the criticisms have in view only the abstract, when the problem is with the concrete, where the judgment of the engineer is supreme; that the supposititious claims thus far made long ago had faithful and complete consideration; and hence the work of the engineers must have been of rare fidelity considering the magnitude of the many problems and the difficulties of work in a tropical wilderness where the vision is limited by the range of the machete.

Yours truly, Boyd Ehle.

Tonawanda, N. Y., Nov. 6, 1896.

Specifications for Water Tube Boilers for the St. Louis Water-Works.

Sir: The editorial on this subject in your issue of the 29th ult. is quite interesting, although not altogether complete. Being familiar with this work, and my relations being close with all the parties interested, I take the liberty of adding something to the discussion.

The work was under the immediate supervision of Water Commissioner M. L. Holman, who is a Vice-President of the American Society of Mechanical Engineers, a member of the American Society of Civil Engineers, and an ex-President of the Engineers' Club of St. Louis. In my opinion the matter has been handled in strict accord with advanced engineering practice, and is deserving of proper credit.

You express surprise that bids were received on only a few of the water tube boilers which were admissible under the specifications. This was probably due to the requirements of paragraph 2, that no boiler would be considered which did not have an established record of 65% efficiency with common Illinois coals. Unfortunately, very few makers of this type of boiler have made sufficient study of fuel economy under these conditions, to establish particularly creditable records. The St. Louis Water Department has had some rather unpleasant experiences with boilers, which although possessing excellent records with good coal had not been adapted to lower grades of fuel, and it was to avoid further experience with untried boilers that this clause was inserted.

You take the position that there should be no material difference in efficiency between any of the boilers admissible under these specifications. In my opinion this is begging the entire question, eliminating as it does the problems of size and angle of tubes, draft areas, circulation, heating and grate surface per unit of work done, ratio of heating to grate surface, draft required, water areas, path of hot gases, etc. Experience has shown us that there is quite a difference between the different types, not only of water tube, but of all other kinds of boilers. Those manufacturers who have made a study of boiler efficiency with Western low grade coals have developed designs which appear to be materially better than those which have been designed and developed for Eastern fuels. In my own experience I have in one case easily developed a horse-power on 3.56 sq. ft. of heating surface, and in another found it difficult to do the same work with 11.

In the specifications referred to, you criticise the exclusion of what in your opinion are the most important features of a boiler—the dimensions of heating and grate surface. I cannot see what difference this makes when we specify the amount of water to be evaporated, the efficiency, the dryness of steam and the required smoke performance. It seems to me that—within reasonable limits, of course—it is absolutely immaterial whether the bidder furnishes one or fifty square feet of heating or grate surface to do a given amount of work. If there were to be any preference, it would seem to be in favor of the man who did the work with the least amount of material, thus occupying less space and requiring less looking after.

Neither can I agree with your implied criticism that both Illinois coals, and Thompson calorimeters, "are apt to be very erratic." Such an opinion is not borne out by extended experience. I recently read before the Engineers' Club of this city a paper on "Boiler Efficiency, Capacity and Smokelessness, with Low Grade Fuels," which is now in the hands of the publisher and will appear shortly. Accompanying this paper are a large number of calorimeter determinations and proximate analyses of Southern Illinois coals coming regularly to this market. These figures show a striking uniformity of the coal from the same mine and of the same grade, as well as a surprising harmony between the proximate analyses, and the calorimetric determinations made with the Thompson calorimeter. For instance, the entire range of Mount Olive coal, between screened lump and slack, shows a difference of less than 5% from the average, while coal of one size varies less than 3% from the average. Coals from different mines, and of different sizes from the same mine, vary considerably, but coal from a certain mine and of the same size, shows no variation which can be termed "erratic."

Neither can I see how there can be any uncertainty in bidding on work of this kind, and I must respectfully protest against the use of the term "guess-work" in this connection. When the kind of coal is specified, the mine from which it must come, its calorific value, the method of determining its calorific value—all are clearly stated—it seems to me that every reasonable cause of uncertainty is removed. If a boiler manufacturer has had much experience with coal of this character and knows what his boiler is capable of doing, there is in my opinion much less "guess-work" as to the efficiency he is going to secure than there would be, for instance, in estimating in advance what it was going to cost him to construct and erect the eight boilers in question. In the present case, considerable time was given in advance of receiving bids, so that interested boiler-makers could conduct investigations with a view of ascertaining what their boilers would do, and I happen to know that at least two of the bidders did conduct such trials; and I know also that it was the intention of the O'Brien Co. to set up a boiler in their works and conduct a further extended series of experiments upon it, to determine the exact conditions under which it would give the maximum efficiency.

I am fully convinced that if those boiler-makers who do not approve of this way of letting boiler contracts will take the matter up and study it further, they will find that it does them no injustice, but on the contrary promises to accomplish just what it is intended to do, namely, secure the most economical type of boiler that can be built. It is, of course, unfortunate that legal complications have prevented the installation of this plant under the original specifications, and I am in a position to assure you that Mr. Holman's change of plan is not due to any lack of confidence in the method, but merely because further procedure on any line admitting competition between the two types of boilers in controversy would undoubtedly reopen the legal complications which prevented the first letting. As the city wants boilers and not lawsuits, Mr. Holman is simply taking the most direct means to accomplish his purpose.

This plan of buying boilers is not at all new. It was used by Mr. Holman himself at the Chain of Rocks boiler plant some years ago, and more recently in my own practice in the case of the boiler plant in the new City Hall here, and the Y. M. C. A. Building. Neither is it uncommon to omit all reference to either heating or grate surface, simply specifying the work to be done, thus avoiding the controversy between different manufacturers as to the amount of heating surface required to do certain work. I repeat that when a steam user buys a boiler he wants ability to evaporate a certain quantity of water per hour, and not so many feet of heating or grate surface.

I am inclined to agree with you that the O'Brien bid included a rather larger amount of heating surface than was necessary, but these people being comparatively newcomers in the water tube field, felt that they could afford to be generous in their proportions.

Respectfully yours, William H. Bryan.

St. Louis, Mo., Nov. 7, 1896.
